ARTS and SCIENCES.

T

T, A consonant, and the nineteenth letter in the alphabet; the sound of which is formed by a strong expulsion of the breath through the mouth, upon a sudden drawing back of the tongue from the fore part of the palate, with the lips at the same time open.

The T, at the beginning and end of words, has always the same sound, nearly resembling that of D, for which reason they are often put for each other; and Quintilian even rallies those who made any scruple of writing the one indifferently for the other: as *at* for *ad*, *set* for *sed*, *haut* for *haut*, &c.

The customary sound of T is that which occurs in the words *take*, *temptation*; but before an *i*, when followed by a vowel, it has the sound of an obscure *s*, as *nation*, *salvation*, except when *s* precedes *t*, as *Christian*; and in derivatives from *y*, as *mighty*, *mightier*.

The T is one of the five consonants which the abbot de Dangeau calls *palatal*: these five are *D*, *T*, *G*, *K*, and *N*; the four first of which have the same relation to each other, as the labials *B-P* and *V-F* have; *D*, for instance, having the same relation to *T*, that *B* has to *P*, and *V* to *F*.

The T, the same author observes, is a letter of a strong sound; so that a feeble one cannot be heard before it. Hence, to form the supine of *rego*, the *T* of *tum* changes the *g*, and strengthens it to the sound of a *c*, so that we say *reſtum*; as in the preterperfect tense *rexi*, which we pronounce *reckſi*.

Th has two sounds: the one soft, as *thus*; the other hard, as *thing*. The sound is soft in these words, *then*, *thence*, *there*, with their derivatives and compounds, *that*, *these*, &c.; and in all words between two vowels, as *father*; and between *r* and a vowel, as *burthen*. In other words it is hard, as *thick*, *thunder*. Where it is softened at the end of a word, an *e* silent must be added, as *breath*, *breathe*. Johnson.

VOL. XXXV.

T

T is used as an abbreviation on ancient monuments, &c. for Titus, Titius, and Tullius.

T, among the *Ancients*, was used as a numeral letter, signifying 160, according to the verse,

“ T quoque centenos & sexaginta tenebit.”

When a dash was at the top, thus, \overline{T} , it signified 160 thousand.

T, with a kind of acute accent over it, denoted among the Greeks 300; and if the accent was below it, thus $\underset{\cdot}{T}$, it denoted 300,000. The ט of the Hebrews signified 9; and with two points fixed horizontally over it, thus, $\overline{\overline{\text{ט}}}$, it signified 9000.

Sometimes an acute accent over this, or any one of the first nine letters, multiplies its value by a thousand.

We shall here observe, that the number 15 should be represented by יה, *i. e.* 10 and 5; but, because these letters constitute part of the word יהוה, *Jehovah*, the letters ט, *i. e.* 9 and 6, represent 15, to prevent, as the Jews allege, the profanation of the peculiar name of God. For the same reason, ט, *i. e.* 9 and 7, are used instead of י, *i. e.* 10 and 6, to express 16.

T, on the French coins, denotes those that were struck at Nantes.

When the Roman tribunes approved of the decrees of the senate, they testified their consent by subscribing a T.

T, in *Music*, is the initial of tenor, vocal and instrumental; of *tacet*, for silence: as *adagio tacet*, when a performer is to rest during the whole movement. In concertos and symphonies, *t* is the initial of *tutti*, the whole band, after a solo part. It also frequently stands for *trillo*, or *tr*, a shake.

T is also a mark or brand, with which by stat. 4 Hen. VII. every person convicted of felony, false murder, and admitted

B

to

to the benefit of the clergy, shall be marked on the brawn of the left thumb.

T, or TAU, in *Heraldry*, is a kind of cross-potent, or truncated; found in all the armories of the commanders of the order of St. Anthony.

The azure T, or Tau, is seen in arms above 400 years old. Its origin, according to some authors, is taken from the Apocalypse; where the same is a mark that the angel impresses on the foreheads of the elect: others take it to represent a crutch, a symbol proper enough for this order, which was sworn to hospitality. But the truth, F. Menestrier observes, is, that it is the top of a Greek crossier.

The bishops and abbots of the Greek church wear it still; and if it be found on the habit of St. Anthony, it is only to shew that he was an abbot.

T *Bandage*, in *Surgery*, is so called from its resembling that letter in shape. It consists of two bands of linen, of greater or lesser breadth, according to circumstances. The transverse piece of the bandage serves to go round the body above the hips. The perpendicular portion is sewed at one of its ends to the middle and back point of the band, which surrounds the pelvis; and its other or anterior extremity is generally slit into two portions, or tails, about six or eight inches in length. The perpendicular piece of the T bandage applies itself between the glutei muscles and to the perinæum; while the two tails, which we have just now described, are carried between the thighs and the pudenda to the right and left, and are lastly fastened to the transverse piece, which surrounds the body. The T bandage is chiefly employed for keeping on the dressings, after the operation for the fistula in ano, in diseases of the perinæum, and in those of the anus, groins, &c.

Besides the common T bandage, surgeons make use of another, which they call *double*, and which is furnished with two perpendicular pieces, sewed to the transverse one, about four inches apart. The double T bandage is represented to be particularly calculated for cases of lithotomy, and for diseases in the perinæum; because the two perpendicular bands may be made to cross each other on the part affected, and leave the anus uncovered; an advantage which the single T bandage certainly has not.

The T bandage admits of application also in other modes. When the cross band is broad, it may be applied round the chest, while the perpendicular portion, being slit into two, may be made to pass over the shoulders, so as to keep the bandage from slipping downward. There is no kind of bandage which can be more conveniently applied to the chest, than that which has just now been described. See **BANDAGE**.

TA, in *Geography*, a fortified city of China, of the second rank, in the province of Se-tchuen; 650 miles S.W. of Pekin. N. lat. $31^{\circ} 18'$. E. long. $107^{\circ} 15'$.—Also, a river of China, which runs into the East sea, N. lat. $36^{\circ} 55'$. E. long. $121^{\circ} 34'$.

TA, *Lough*, a lake of the county of Wexford, Ireland, not far from Carnfore Point. It receives two or three smart rivulets, and having no outlet, the waters accumulate, and gradually overflow the adjacent grounds; till the peasantry, once in three or four years, let them off, by making a cut through the high sand-bank that parts the lake from the sea; which cut very soon fills up again.

TA, a name given in China to their pagodas. These are most numerous in hilly parts of the country, upon the summits of which they are frequently erected. They are generally from 120 to 160 feet high, which height is equal to four or five of their diameters at the base; and they consist mostly of an unequal number, five, seven, or nine galleries

or stories, diminishing as they rise, with as many projecting roofs.

TA, τα, one of the four syllables used by the ancient Greeks in solmification, or the first lessons in fingering.

TAAIF, in *Geography*, a town of Arabia, in the province of Hedsjas, situated upon a lofty mountain, in a country so agreeable, that the Arabs compare its environs to those of Damascus and Sana. This city supplies Jidda and Mecca with excellent fruits, particularly raisins; and carries on a considerable trade in almonds, which abound in its territories. Near Taaif is the lofty mountain of Gazvan, which, according to Arabian authors, is covered with frost and snow in the midst of summer.

TAAMBOOTERA, a large town of the Birman empire, on the Irawaddy.

TAAPAN, a town on the east coast of Mindanao. N. lat. $7^{\circ} 38'$. E. long. $124^{\circ} 5'$.

TAAS, or TAÆS, a city of Arabia, in the province of Yemen, situated at the foot of the fertile hill of Sabber, and encompassed with a wall, between 16 and 30 feet thick, and flanked with several towers. Within the circuit of the wall stands the fortress of Kahhre. The city has only two gates, each fortified with three towers; affording a very insufficient defence against any assault but that of Arabs, unskilled in the use of artillery. The saint who is the patron of TAÆS is the famous Ismael Mulk, reported by tradition to have been once king of this country. His remains are interred in a mosque bearing his name. Near this mosque is a garden, which was possessed by Ischia, his son. The city has several other deserted and ruinous mosques. The last lords of TAÆS have chosen to distinguish themselves, not by mosques, but by noble palaces, and have contented themselves with a small kubbet for their oratory and burial-place. These palaces are now the ornaments of the city. Near the city are the ruins of two ancient cities: one called Thobad, situated near mount Sabber; and the other Oddena, upon the summit of mount Sabber, over-against Kahhre. This was formerly the residence of the kings of the country. Its only remains are the ruins of some mosques. TAÆS has undergone several revolutions; but after various events, which we cannot recite, the Imam sent a Dola to this city, and it is now under the same government as the other cities in his dominions; 48 miles E.N.E. of Mocha. N. lat. $13^{\circ} 33'$. E. long. $44^{\circ} 10'$.

TAASINGE, an island of Denmark, about 16 miles in circumference, situated between Funen and Langeland, with a town upon it of the same name. N. lat. 55° . E. long. $10^{\circ} 37'$.

TAAUT, THOYT, or *Thot*, in *Ancient Mythology*, the name of a deity among the Phœnicians, and probably the same with the Egyptian *Thoyt*, *Thot*, or *Hermes*, the *Theutate* or *Teutat* of the Greeks, and the *Mercury* of the Latins. His cosmogony has been transmitted to us by the Phœnician writer Sanchoniathon, whose account is preserved by Eusebius, De Præp. Ev. lib. i. cap. 10. To him the Phœnicians ascribe the first invention of letters. See **MERCURY**.

TAAWIRRY, in *Geography*, an island in the South Pacific ocean. There are two situated within the reef of the island of Otaheite, and on the east side of the main island. Within these islands there is anchorage within the reef that surrounds them. The French vessels under the command of M. Bougainville lay here. The name of the other island is Boourou.

TAB, the ancient *Arofis*, a river of Persia, in the province of Fars or Farfitan, formed by the junction of two streams, within a few miles of the town of Zeitoon. Both these

these streams take their rise in the recesses of the mountains of Fars; the first at the foot of the high hill of Kamarah, and the other near that of Ardicoone, 12 furlongs (the furlong being estimated at three English miles and three quarters) N.W. of Shirauz. This branch of the river is mentioned by Arrian in the march of Alexander. It divides Fars from Chufistan, and passes through the centre of the town of Endian, being navigable for boats of 20 tons burthen. Nine miles above the town is a ford; and 16 miles below it, the Tab falls into the sea. When the river passes Zeitoon, the waters are perfectly sweet; but in its course over the hills, towards Endian, they become corrupted, and at that place are so brackish as to be hardly fit for use.

TABA, a town of Africa, on the Grain Coast.

TABA *Islands*, four small islands in the East Indian sea, lying north-west and south-east near the east coast of Borneo. N. lat. 2° 6'. E. long. 118° 12'.

TABA, or *Tabo-feil*, in *Modern History*, a name by which the Negroes, who inhabit the Gold Coast in Africa, describe their king, whose power is very arbitrary, inasmuch that they regard him as a being superior in nature to themselves.

TABAB MANAM, in *Geography*, a town of Abyssinia; 100 miles S.S.E. of Gondar.

TABACUM, in *Botany*, whence comes its common English name Tobacco, or, at present, Tobacco. (See NICOTIANA.) Bauhin says, after Monardes, that this appellation is derived from an island so called; but it should seem to originate from the Indian name of the plant, *Tubac*, or *Tubacka*.

TABÆ, in *Ancient Geography*, a town of Asia, in Cilicia.—Also, a town of Asia, on the confines of Pisidia, on the coast of the sea of Pamphylia.—Also, the name of three towns in Asia Minor; one in Caria, another in Peræa, and a third in Lydia.

TABAFRA, in *Geography*, a town of Africa, on the Ivory Coast; 15 miles E. of Druin.

TABAGO, an island in the Pacific ocean, near the coast of Mexico; about three miles long, and two broad. It is mountainous, and on the north side the high land declines with a gentle descent to the sea. Near the strand the soil is a black mould, and deep, but towards the top of the mountain strong and dry. The north side of the island makes a very pleasant appearance, and seems to be a garden of fruit-trees, inclosed with others of the forest-kind. The principal products are plantains and bananas, which grow very well from the foot to the middle of the mountain; but those near the top are small, as wanting moisture. There was formerly a small town near the sea, on the north side of the island; but it was ruined by the privateers that then frequented those seas. Before it is a good road, about a mile from the shore, where ships may ride very safely in 16 or 18 fathom water; 18 miles S. of Panama. N. lat. 8° 40'. W. long. 80° 9'.

TABAGUILLA, or *Little Tabago*, a small island in the Pacific ocean, near Tabago.

TABAJANA, a town of Africa, in the country of Woolly; 12 miles W.S.W. of Medina.

TABALLAR POINT, a cape on the east coast of the island of Borneo. N. lat. 2° 12'. E. long. 117° 4'.

TABALTHA, in *Ancient Geography*, a town of Africa, on the route from Tuburbum to Tacapæ, between Cellæ Picentiniæ and Septimunicia. Anton. Itin.

TABALUM, a town of Asia Minor, in the vicinity of Ionia. Herodotus.

TABANA, MANKOUP, a town in the interior of the Tauric Chersonesus. Ptol.

TABANIE', in *Geography*, a town of Egypt, on the east branch of the Nile; 6 miles S.W. of Manfara.

TABANUS, the *Ox-fly*, in *Entomology*, a genus of the Diptera order of insects; the generic characters of which are, that the mouth has a fleshy proboscis, terminated by two lips, and that the rostrum is furnished with two awl-shaped palpi, placed on each side of, and parallel to, the proboscis. Gmelin, in his edition of the Linnæan system, enumerates 38 species.

The insects of this genus very much resemble those of the *Musca*; which see.

Species.

ROSTRATUS. With brownish eyes, and sucker of the length of the body.

BARBATUS. With black eyes, and sucker half the length of the body. Both these species are found at the Cape of Good Hope.

MAURITANUS. With blackish eyes, a black spot on the second segment of the abdomen, and sucker equal to the body. Found in Barbary and Spain.

BOVINUS. Greenish eyes; marked down the back by a series of large, whitish, triangular spots, and on each side is a similar appearance, but less distinct than that of the dorsal row. This is the largest of the British species, and, like others of its species, is seen generally in the hottest part of the day, during the middle and the decline of summer. It is very troublesome to cattle. Its larva is large and dusky yellowish, like that of a tipula, marked by transverse blackish streaks or rings; residing under ground in moist meadows, &c.; and changing into a cylindrical brownish chrysalis, with a roundish or slightly pointed extremity, from which within a month proceeds the perfect insect.

AUTUMNALIS. With glassy wings, and brown abdomen, and a whitish three-fold spot. Found in Europe.

CALANS. With green eyes, a white line on the back, and red antennæ. Found in South America.

TARANDINUS. With green eyes and feet, and the segments of the abdomen yellowish at the margin. Found in the north of Europe.

EXÆSTUANS. With green eyes, the segments of the abdomen white at the margin, and whitish legs. Found in Surinam.

FERVENS. With green eyes, yellow abdomen and antennæ, and brown head and thorax. Found in South America.

MEXICANUS. With a livid body, green antennæ, and greenish wings. Found in Surinam.

RUSTICUS. Cinereous, with grey eyes, and two black points in the front. An European insect.

BROMIUS. With a purple fascia about the eyes, and cinereous body. Found in Germany, and the northern part of Europe.

OCCIDENTALIS. With eyes having double brown fasciæ, a brown body, and the abdomen marked with three yellow lines. Found in Surinam.

TROPICUS. With eyes having triple purplish fasciæ, and the sides of the abdomen ferruginous. An European insect of a brown colour, smaller than *T. bovinus*, and less common, troublesome to cattle, and especially to horses.

ANTARCTICUS. With eyes like the former, black abdomen, and segments with whitish margins. Found rarely in Norway.

PLUVIALIS. With eyes waved with four-fold fasciæ, and brown-speckled wings. This is an European species, very troublesome with us in the latter part of summer, fastening

on the legs, hands, &c., and peculiarly teasing on the approach of rain.

CZCUTIENS. With eyes that are of a very lucid green, marbled with black spots and streaks; and wings marked by large black bands or patches. This is an European insect, not uncommon with us in autumn.

LUGUBRIS. With black eyes and body, brown wings, and white spots. Found in Europe.

MORIO. With eyes and body wholly black, and glassy wings. An inhabitant of Barbary.

LINEATUS. With greenish eyes, lineated thorax, obscurely blueish abdomen, and red antennæ. Found in America.

FASCIATUS. With green eyes, brown body, and wings having a brown fascia. Found in Sierra Leone.

ATRATUS. With blueish abdomen, and black wings. An American insect.

PELLUCENS. Black, with fasciated eyes; the first segment of the abdomen blueish, and whitish legs. A German species.

RUFICORNIS. With fasciated eyes, white wings, brown side, and red antennæ. Found in America.

PAGANUS. With green eyes, three yellow fasciæ, and both sides of the abdomen ferruginously spotted. Found in England.

ITALICUS. Cinereous, with brown eyes; obscure abdomen, with the base palely pellucid. Found in Italy.

CAYENNENSIS. With eyes brown before, and behind green; black abdomen; the second and third segments yellow, the rest white at the margin. This and the next are found in Cayenne.

PUNCTATUS. Cinereous, with testaceous eyes, and white wings speckled with black.

INANIS. Cinereous, like the former, with brown eyes, and pellucid abdomen, having a brown apex.

BOREALIS. With eyes having three purplish fasciæ, black abdomen, and the margins of the segments whitish. Found rarely in Norway.

LONGICORNIS. With spotted eyes, wings half brown, a white spot, and longer antennæ. Found in Brasil.

STRIATUS. Cinereous, with brown abdomen, and three abbreviated white lines. A Chinese species.

BIDENTATUS. Ferruginous; the abdomen having on each side two yellow spots, and the scutellum bidentated. Found in Aultria.

BISPINOSUS. Brown, ferruginous, abdomen black at the base, and scutellum bispinose. Found in Gottingen.

MÆRENS. Varied with whitish and black; black eyes; white wings; side and fascia black. Found in Cayenne.

GRISEUS. Black, with greyish thorax; the second segment of the abdomen having on the hind part a cinereous fascia, the fourth, fifth, and sixth being on both sides cinereous, and the wings ferruginous.

ALBIDES. With eyes having four fasciæ; the abdomen with a black ring, and the legs white. Found in Bulgaria.

MARITIMUS. Cinereous, with glassy wings; margin and broad fascia black. Found in Carniola, Aultria, and France.

TABARA, in *Geography*, a town of Spain, in the province of Leon; 14 miles N.W. of Zamora.

TABARABA, a river of Mexico, in the province of Veragua, which runs into the Pacific ocean, N. lat. 8° 40'. W. long. 82° 48'.

TABARCA, a town of Africa, in the kingdom of Tunis, situated on the north coast, at the mouth of the Zaine, of which little but ruins are existing, and a small garrison; 60 miles N.W. of Tunis.

TABARCA, or *Tabaquer*, an island in the Mediterranean, near the coast of Africa, at the mouth of the river Zaine, which separates Algiers from Tunis. The Lomelines, a noble Genoese family, have been in possession of the little island that lies before Tabarca, at the mouth of the Zaine, ever since the time of the famous Andrea Doria, to whom the Tuniseans gave it, with the solemn consent of the grand seignior, in ransom for one of their princes, whom Andrea had taken captive. This place is defended by a small castle, well armed, and in good order, and protected the coral fishery which was carried on in these seas. But, in the year 1740, that monster of princes, Aly Bashaw, the reigning king of Tunis, took it by treachery from the Genoese; and, contrary to all justice and the right of nations, put some of them to the sword; and the rest, in number 300 or 400, he carried into captivity. N. lat. 36° 55'. E. long. 9° 8'.

TABARCA. See **PLANA**.

TABARD, or **TABERD**, derived from the low Latin *tabarda*, denotes a short jacket or coat, open on both sides, with a square collar and hanging sleeves. From the wearing of this garment, some of those on the foundation of Queen's college, Oxford, are called *Taberdarii*.

From an inn in Southwark, whose sign was the *Tabard*, afterwards changed to the *Talbot*, Chaucer and his companions set out on a pilgrimage to the shrine of Becket at Canterbury; on which was founded his *Canterbury Tales*.

TABAREK, a town of Persia, in the province of Irak; 8 miles S.E. of Casbin.

TABARIA, or **TABERAYAN**, or *Tabarieb*, anciently *Tiberias*, a town of Palestine, situated on the west bank of a lake, called in the scriptures the "Lake of Gennesareth," and the "Sea of Tiberias," and at the foot of a high and sharp mountain; surrounded with walls, except towards the water. This town was built by Herod Antipas, to the honour of Tiberius, and was long the capital of Galilee, and after the destruction of Jerusalem, for some time the residence of the high priest. This city Herod was obliged to people mostly with Galileans and strangers, because it being built on a ground which was full of sepulchres, he could scarcely get any of that nation to settle there, though he endowed it with considerable privileges, and gave its inhabitants the greatest encouragement, viz. lands to some, houses to others, to take off their qualms of conscience about treading on dead bodies. At the destruction of Jerusalem the town submitted to Vespasian, and received the Jews which escaped. In the year 1100, it was taken by the Christians under Godfrey; but in 1116, it was retaken by the Saracens, through the treachery of Raymond III. count of Thouloufe. During the time of Christianity it was the see of a bishop, suffragan of Nazareth. Near it are some warm baths. The Christians have a church here, and the Jews a seminary. In 1759, it suffered much by an earthquake; 16 miles S. of Safad.

TABAS, a town of Asiatic Turkey, in Natolia; 34 miles S. of Dignizlu.

TABAS, the ancient *Tabienne*, a town of Persia, in the province of Chorasan, situated in a range of hills, 337 miles from Herat and 150 from Yezd. It contains a population of about 20,000 persons, and carries on a trifling trade with Herat and Yezd.

TABASCO, a province of Mexico, bounded on the north by the gulf of Mexico, on the east by Yucatan, on the south by Chiapa, and on the west by Guaxaca, about 100 miles in length, but narrow. The climate is not reckoned healthy, nor is the soil remarkable for its fertility.

The

The inhabitants, however, have good farms well-stocked with cattle, which sell to good advantage. They have also great plenty of Indian corn and cocoa-nuts, which they send to Vera Cruz. Most of the country is flat and moist, has many marshes and lakes well-stocked with fish. It rains nine months out of the twelve, so that the air is excessively damp; and in February, March, and April, remarkably hot, when infinite swarms of gnats and other insects are produced. The coast, from the beginning of September to the end of March, is subject to tempestuous northerly winds, which render sailing dangerous during that season. The Spaniards brought hither vines, lemon, orange, and fig trees, which all thrive here very well. Here are large thickets of mangroves and bamboos, and woods of cedar, Brazil wood, &c. frequented by lions, tigers, wild bears, and deer. They have a great number of rabbits, apes, and squirrels, with the common fruits of America; and three or four harvests of maize in a year; besides rice, barley, and all sorts of garden-herbs, different species of European fowls, and others to us unknown. This province was accustomed to pay its tribute to the ancient kings of Mexico in chocolate.

TABASCO, a river of North America, which runs into the bay of Campeachy, N. lat. $18^{\circ} 15'$. W. long. $93^{\circ} 40'$. On the banks of this river are some of the largest cabbage and cotton trees supposed in the world.

TABASCO, a town of Mexico, and capital of a province, to which it gives name, called also by the Spaniards "Nuestra Señora de la Vittoria," from a great victory obtained here by Cortez, on his first arrival. It stands on an island, at the mouth of the river Grijalva, which divides itself near the sea into two branches, of which the western falls into the river Tabasco, which rises in the mountains of Chiapa; and the other continues its course till within four leagues of the sea, where it subdivides, and separates the island above mentioned from the continent. Near it are plains, which abound with cattle and other animals, particularly the mountain-cow, so called from its resembling that creature, and feeding on a sort of moss found on the trees near great rivers. The island of Tabasco, on which the town of that name is built, is about 12 leagues long and $2\frac{1}{2}$ broad. The town is not very large, but well-built, and considerably enriched by a constant resort of merchants and tradesmen at Christmas. N. lat. $18^{\circ} 20'$. W. long. $93^{\circ} 46'$.

TABASHEER, in *Medicine*, a drug of high repute in many parts of the East, the knowledge of which has been communicated to the western world by the works of the Indian physicians, by all of whom it is mentioned as an important article in the *Materia Medica*; and it is still considered to be administered under this and other names in Turkey and in various parts of India. The Arabian medical writers generally agree, that the Tabasheer is a production of the Indian reed. The genuine Tabasheer, according to Dr. Patrick Russell (*Phil. Transf.* vol. lxxx. p. 275.) is undoubtedly a production of the *Arundo Bambos* of Linnæus; and the bamboo in which it is found, is vulgarly called the female bamboo, and distinguished by the largeness of its cavity from the male, employed for spears and lances. The bamboo, however, yields this drug only in a small quantity, varying according to the soil or situation in which the bamboo grows. For a farther account of it, we refer to the *Phil. Transf.* ubi supra. See **ARUNDO**.

TABASO, in *Ancient Geography*, a town of India, on this side of the Ganges, between Bynda and Pseudofiomus. Ptol.

TABASSERAN, in *Geography*, a district of the tract of land situated along the Caspian sea, between the rivers Terek

and Kur, and one of the divisions of the province of Daghestan, dependent on Persia. It lies between the Durbach and Rubas, towards their sources; extending about six German miles inland from above the territory of Derbent as far as the highest ridge of the Lefgian mountains, which is here very rocky and woody. Reineggs calculates the strength of the different tribes inhabiting Tabasseran, who, besides the Tartarian, speak another language peculiar to themselves, at about 10,000 families: and, according to him, the reigning family have held the sovereignty over the country for more than 600 years. See Reineggs' *General Historico-topographical Description of Caucasus, &c.* The town of Tabasseran is the residence of a prince, and the centre of the trade carried on between Persia and Daghestan.

TABAXIR, in *Botany*, pronounced *Tabasheer*, appears to be a Persian name, appropriated to the Bamboo, *Arundo Bambos* of Linnæus, or rather originally to an internal secretion of the stem of that plant. This is at first of a milky aspect, but subsequently concretes into a solid form, and very hard substance, compared to fugar, but more like sand or pebbles, being indeed a real siliceous earth. The discovery of its true nature was made by Mr. Macie, now Smithson, and published in the *Philosophical Transactions* for 1791, vol. viii. p. 368. See **ARUNDO**, and **TABASHEER**.

TABAZET, a word used by some writers to express highly-refined fugar.

TABBAJEE, in *Geography*, a town of Africa, in Neola. S. lat. $13^{\circ} 32'$. W. long. $11^{\circ} 8'$.

TABBAY, one of the Western islands of Scotland, near the east coast of Skye. N. lat. $57^{\circ} 16'$. W. long. $5^{\circ} 51'$.

TABBY, a mixture of stone and mortar, which becomes as hard as a rock, used in Morocco. The walls of the city are formed of this substance.

TABBY, in *Commerce*, a kind of thick silk, usually watered. It is manufactured like the common taffety, excepting that it is stronger and thicker both in the wool and warp.

The watering is given it by means of a calender, the rolls of which are of iron, copper, or wood, which, bearing unequally on the stuff, render the surface of it unequal, so as to reflect the rays of light differently.

TABBYING, or **WATERING**, the passing a stuff under a calender, to make the representation of waves on it as on a tabby. It is usual to tabby mohairs, ribbands, &c. Tabbying is performed without the addition of any water, or dye; and furnishes the modern philosphers with a strong proof that colours are only appearances.

TABE, in *Geography*, a river of Prussia, proceeding from the Niemen, and running into the Curisch-Haff.

TABEA, in *Ancient Geography*, a town of Asia Minor, in the Greater Phrygia. Strabo.

TABEIPILLY, in *Geography*, a town of Hindoostan, in Mysore; 25 miles W.N.W. of Bangalore.

TABELLA, or **TABLET**, *Tabularium*, in *Pharmacy*, a solid kind of electuary, or confection, made of dry ingredients, usually with fugar, and formed into little flat morsels, or squares, more usually called *lozenges*, and sometimes *morfelli*, *troches*, &c.

Powders, fruits, salts, &c. are dissolved with fugar, and made into *tabule*, as those of the juice of liquorice for colds, &c.

We have *cordial*, *stomachic*, *aperitive*, and *hepatic* tablets. Jellies and broths are sometimes reduced into a sort of tablets, to be carried in the pocket, and called *pocket-saup*. *Tabella manus Christi* are made of fugar of roses pearled. *Tabella magnanimitatis* are a sort taken by feeble old men,

when matched with young wives, to assist them in the affair of generation.

TABELLÆ Volivæ, in *Antiquity*, a name given to certain tablets, which were hung up in the temples: for, according to an ancient custom, which prevailed all over Greece, such as recovered from any distemper used to write in a tablet the nature and symptoms of their respective maladies, and the remedies which had been most successful. These tablets Hippocrates is said to have copied and followed when he first began to practise: and, if we believe Pliny (lib. vii. c. 37.), he learned from these the first rudiments of physic.

A tablet of this nature was discovered at Rome, not many years ago, among the ruins of the ancient temple of Æsculapius, with this inscription in Greek. Julianus being afflicted with vomiting of blood, and abandoned by men, the gods hastened to his relief, and having nourished him for the space of three days with honey, restored him to his health: for which favour he came to return them thanks in the presence of the people. Tables of a similar kind, under the same denomination, were hung up in the temples by those who had escaped shipwreck, &c.

TABELLIO, **TABULARIUS**, in the Roman law, a *scrivener*; a kind of officer often confounded with the notary, *notarius*: yet the two differed in this; that the notaries only drew up and kept the minutes of acts and instruments on paper, and in notes, or short-hand; whereas the tabelliones delivered them engrossed fair, on parchment, in the full executory form. The same also put the seals to contracts, and rendered them authentic.

The domestic clerks of these tabelliones, who at first wrote under them, in process of time came to be called *notaries*.

Pasquier observes, that the tabelliones at Rome were public slaves, appointed for the keeping of contracts made between private persons. According to Loyseau, a contract written by a notary was not perfect, or obligatory, till the tabellio had written it fair: after which, the parties subscribed it, *i. e.* they wrote at bottom, that they approved the contents; for signatures were not then in use. See **SIGNATURE**.

“Quoniam tabellionum usus in regno Angliæ non habetur, propter quod magis ad sigilla authentica credi est necesse, ut eorum copia facilius habeatur, statuimus, ut sigillum habeant non solum archiepiscopi, et episcopi, sed eorum officiales.”

TABENNE, in *Geography*, an island in the river Nile, between Dendera and the ruins of the ancient Thebes; famous on account of the retreat of the monk Pacomius and several hundred of his brethren.

TABENUS CAMPUS, in *Ancient Geography*, a country of Asia Minor, on the confines of Phrygia and Mysia. Strabo.

TABERG, in *Geography*, a town of Sweden, in the province of Smaland, situated on a mountain of the same name, which abounds in iron-ore; 2 miles S. of Jonkioping.

TABERISTAN. See **MAZANDERAN**.

TABERN, in *Rural Economy*, a term sometimes applied to a cellar, or other similar excavation, for the containing of liquor of the domestic kind.

TABERNA MERITORIA, among the Romans, Mars' hospital, or a place where disabled soldiers were maintained at the charge of the government.

TABERNACLE, **TABERNACULUM**, *q. d.* a tent; among the Jews, was a kind of moveable chapel, so contrived as to be taken to pieces, and put together at pleasure, for the convenience of carrying it from place to place, during the migration of the Israelites in the wilderness for forty years.

It was erected by Moses, in consequence of the express command of God, partly to be a palace of his presence as the king of Israel, and partly to be the medium of the most solemn public worship, which the people were to pay to him. It was erected on the first day of the first month of the second year after the Israelites' exodus from Egypt. Exod. xl. 2. 17. 26. 29. 34. 35.

The tabernacle was of a rectangular figure, thirty cubits long, ten broad, and ten high; or, according to Dr. Cumberland's reduction to English measure, fifty-five feet long, eighteen broad, and eighteen high. The two sides and one end were composed of broad boards, standing upright; each board being about two feet nine inches broad, fastened at the bottom by two tenons in each board, fitted into two mortises on the foundation; at the top by links or hasps, and on the sides by five wooden bars, which run through rings or staples in each of the boards. Each side consisted of twenty of these boards, and the end of eight. Both the boards and bars were overlaid with gold; and the rings and hasps were of the same metal. The foundation, on which they stood, consisted of solid blocks of silver, two under each board; each of which was about sixteen inches long, and weighing a talent, or about an hundred weight. The number of these blocks was about an hundred; ninety-six of which were laid under the forty-eight boards, and the other four were the bases of the columns that supported the veil or curtain, which divided the inside of the tabernacle into two rooms. Hence some have derived the ancient fashion of setting porphyry columns on bases of white marble.

The tabernacle had four different coverings, or carpets, thrown over one another. The first and lowest was made of fine linen, richly embroidered with figures of cherubims, in shades of blue, purple, and scarlet; and consisted of ten breadths, which were joined together with blue loops and clasps of gold. The next over this was made of a sort of mohair, the breadths of which were joined with clasps of brags. The third carpet was made of ram's skin dyed red; and the uppermost of all was made of *tachafsb*, *i. e.* as has been generally supposed, badger's skins.

The east end of the tabernacle had no boards, but was sheltered with a fine embroidered curtain, hung upon five pillars of Shittim wood, overlaid with gold, and supposed by Philo to touch the ground.

The inside of the tabernacle was divided into two rooms, by means of a veil or curtain, hung upon four pillars; the veil was curiously manufactured of the richest stuff, and adorned with cherubims and other ornaments, embroidered upon it. By this veil the tabernacle was divided, and learned writers have reasonably conjectured, in the same proportion with the temple, afterwards built according to its model: that is, two-thirds of the whole length were allotted to the first room, and one-third to the second; so that the room beyond the veil, which was called the *holy of holies*, was exactly square, being ten cubits each way: and the first room, called the *sanctuary*, was twice as long as broad.

Round the tabernacle there was a spacious court, one hundred cubits long, and fifty broad, surrounded with pillars set in bases of brags, and filleted with silver, at the distance of five cubits from one another. The chief things in this court were the altar of burnt-offering, and the brazen laver. See Exod. ch. xxviii. and ch. xxx.

In the sanctuary, or first room of the tabernacle, were the altar of incense (Exod. xxx. 1—10.), the golden candlestick (Exod. xxv. 31, &c.) valued by Cumberland at upwards of five thousand and seventy-six pounds sterling, and the table of shew-bread, described Exod. xxv. 23—30. Within the second veil, in the holy of holies, was the ark of

testimony, and its lid or cover, called the *mercy-seat*, described Exod. xxv. 10—21. See *ARK of the Covenant*.

The learned Spencer (De Leg. Hebr. diff. i.) suggests, that Moses projected the tabernacle, with its furniture and appurtenances, after the fashion of a similar structure, which he had observed in Egypt, and which was in use among other nations; or, at least, that God directed it to be made with a view of indulging the Israelites in a compliance with their customs and modes of worship, so far as there was nothing in them really sinful: and he alleges evidence of such portable temples among the heathens, in which they deposited the most valuable sacred or religious utensils. But it has been replied to this conjecture, that it is not probable. But, on the other hand, it should seem more likely, that the heathens took these things from the Jews, who derived the whole of their religion from God, than that the Jews, or rather that God should take them from the heathens: and, besides, the Jewish tabernacle was ordered to be directly the reverse of the heathen tabernacles, both in its form, which was capable of being taken to pieces, whereas theirs was carried about entire; and in its situation, which was accommodated to the people's worshipping towards the West; whereas it was the general practice of the heathens to worship with their faces towards the East. (See Ezek. viii. 16. and Virgil *Æneid*. xii. l. 172—174.) The value of the gold and silver only, used for the work of the tabernacle (Exod. xxxviii. 24, 25.), amounted, according to bishop Cumberland's reduction of Jewish talents and shekels to English coin, to upwards of one hundred and eighty-two thousand five hundred and sixty-eight pounds. Jennings's Jewish Ant. vol. ii. b. 2. c. 1. Anc. Univ. Hist. vol. i. part ii. p. 651, &c. folio.

We have also an account of two other tabernacles before the building of Solomon's temple, besides that above described. One of these was erected by Moses for himself; in which he gave audience, heard causes, and inquired of God; and, perhaps, also the public offices of religious worship were performed in it for some time; whence it was called the *tabernacle of the congregation* (Exod. xxxiii. 7.) The other was that which David erected in his own city, for the reception of the ark, when he received it from the house of Obbedom. 2 Sam. vi. 17. 1 Chron. xvi. 1.

TABERNACLES, Feast of. See SCENOPEGIA.

TABERNACLE is also used, of late, for a place of religious worship, appropriated to the use of those that are called Methodists.

TABERNACLE, in *Architecture*, an ornamented chest, generally made of precious wood, metal, or marble, and placed upon Roman Catholic altars, as a receptacle for the ciborium and pyxis.

TABERNACLE, in *Pointed Architecture*, a niche surmounted by a canopy of tracery work.

TABERNÆMONTANA, in *Botany*, was so called by Plumier, in memory of one of the fathers of modern botany, James Theodore, surnamed Tabernæmontanus, that being the latinized appellation of Berg Zabern, a town in the district of Deux-Ponts, where he was born. He died at Heidelberg in 1590, having published a ponderous and learned German *Kreuterbuch*, or Herbal, the wooden figures of which were subsequently printed by themselves, under the title of *Tabernæmontani Eicones*, in long quarto.—Linn. Gen. 118. Schreb. 165. Willd. Sp. Pl. v. 1. 1244. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 71. Swartz Ind. Occ. 535. Brown Prodr. Nov. Holl. v. 1. 467. Plum. Gen. 18. t. 30. Juss. 145. Lamarck Dict. v. 7. 527. Illustr. t. 170.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apocinea*, Juss. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, in five acute converging segments, permanent. *Cor.* of one petal, valver-shaped; tube cylindrical, many times longer than the calyx, tumid at the base; limb horizontal, in five deep, oblong, obtuse, obliquely twisted segments, scarcely so long as the tube. Nectary of five cloven glands, surrounding the germen. *Stam.* Filaments five, small, inserted into the middle of the tube; anthers erect, arrow-shaped, converging, generally enclosed in the tube. *Pist.* Germens two, simple; style solitary, central, thread-shaped; stigma oblong, capitate, cloven, dilated at the base. *Peric.* Follicles two, horizontally spreading, tumid, pointed, each of one cell and one valve. *Seeds* numerous, ovate-oblong, obtuse, rugged, imbricated, imbedded in pulp.

Ess. Ch. Corolla valver-shaped; its limb obliquely twisted, in five deep segments. Anthers arrow-shaped, within the tube. Follicles two, tumid, divaricated. Seeds imbedded in pulp.

“A genus of shrubs, with opposite simple leaves. *Stipulae* between the footstalks, connected below, loose above. *Cymes* somewhat forked. *Calyx* permanent.”—Brown, by whose remarks we have profited in some of the above characters. The species are all of tropical origin, and contain more or less of an acrid milky juice. The flowers are white or yellow, mostly fragrant and ornamental. Two North American herbaceous species, with alternate leaves, and blueish flowers, one of them, *T. Amsonia* of Linnæus, having a funnel-shaped corolla, and no pulp in the fruit, are well separated by Walter, Michaux, and other late writers, under the generic name of *Amsonia*.

1. *T. citrifolia*. Citron-leaved Tabernæmontana. Linn. Sp. Pl. 308. Willd. n. 1. Ait. n. 1. Jacq. Amer. 38. t. 175. f. 13. (*T. lactescens*, citri foliis undulatis; Plum. Ic. 246. t. 248. f. 2. *T. n. 1*; Browne Jam. 182.)—Leaves elliptical, pointed. Panicles axillary, stalked, cymose, of few flowers.—Native of the West Indies. Jacquin observed it in Martinico; Browne in Jamaica. The French in the former island call it *Bois laiteux*, from the milky juice with which every part abounds. The stem is shrubby, erect, branched, from five to eight feet high, smooth like every other part. Leaves opposite, stalked, from four to six inches long, and from two to three and a half broad, of a fine shining pellucid green; paler beneath; wavy at the edges; furnished with a central rib, and many strong, curved, nearly opposite, transverse ones. Flowers white, with a light agreeable scent, in opposite, axillary, somewhat umbellate, stalked panicles, about twice or thrice the length of the footstalks. Jacquin describes the follicles as always green, acute, filled with soft orange pulp, enveloping the brown rugged seeds.

2. *T. laurifolia*. Laurel-leaved Tabernæmontana. Linn. Sp. Pl. 308. Willd. n. 2. Ait. n. 2. Jacq. Amer. 39. (*Nerium arboreum*, folio latiore obtuso, flore luteo minore; Sloane Jam. v. 2. 62. t. 186. f. 2.)—Leaves elliptical, bluntish. Panicles axillary, nearly sessile, cymose, smooth, shorter than the footstalks.—Native of banks of rivers in Jamaica. We have seen no specimen. Sloane describes this as a tree, whose trunk is as thick as one's leg, fifteen feet high, with long crooked branches, leafy at the end. The leaves appear to be rather less pointed than in the former, and of a darker green. Flowers yellow, very sweet-scented; the tube of their corolla half an inch only in length; in the first species it measures full an inch. The flower-stalks are smooth, not scaly. Linnæus erroneously refers Browne's plant to this species, on the authority of Solander, who marked the original specimen *T. laurifolia*.

3. *T. squamosa*. Scaly-stalked Tabernæmontana.—Leaves ovate,

TABERNÆMONTANA.

ovate, bluntish. Panicles from the forks of the branches, cymose, with scaly flower-stalks.—Gathered by Commerçon, in the island of Mauritius. The *branches* are round, forked, rough with minute white tubercles. *Leaves* three or four inches long, and two or three broad, very smooth, opaque, slightly wavy, with one rib, and many transverse veins, on smooth *footstalks* three quarters of an inch in length. *Panicles* in pairs from the forks of the branches, each cloven and somewhat subdivided, divaricated, of about ten apparently white or yellowish *flowers*; their partial stalks clothed with numerous, roundish, imbricated *bractæas*, gradually larger upward, which we have not seen in any other species. Tube of the *corolla* above an inch long; limb somewhat shorter, rough with glandular hairs, on the upper side, about the centre. We cannot refer this to any described species, even in Lamarck.

4. *T. odorata*. Fragrant Tabernæmontana. "Vahl Eclog. Amer. fasc. 2. 22." Poiret in Lamarck Dict. n. 17. (Cameraria Tamaquarina; Aubl. Guian. 260. t. 102. C. lutea; Willd. Sp. Pl. v. 1. 1244.)—*Leaves* elliptic-lanceolate, pointed, smooth and shining, on short stalks. Umbels from the forks of the *branches*, of about four flowers. Corolla slightly downy externally.—Found by Aublet, on the banks of rivers in Guiana, flowering in May. Vahl was induced by the remarks of Von Rohr to remove this plant hither. (See CAMERARIA, n. 3.) The *leaves* in Aublet's specimen are highly polished, about four inches long, and above one wide. *Partial flower-stalks* above an inch long, smooth, naked, simple. *Flowers* yellow, with a sweet pleasant smell; their limb longer than the tube, which measures about three quarters of an inch.

5. *T. echinata*. Prickly-fruited Tabernæmontana. Aubl. Guian. 263. t. 103. Willd. n. 3.—*Leaves* on short stalks, elliptic-lanceolate, pointed; somewhat downy beneath. Umbels dense, many-flowered, from the forks of the branches. Follicles muricated.—Native of Guiana, flowering in August. The *stems* are numerous, knotty, four or five feet high. *Leaves* five or six inches long, and two broad, smooth and green above; clothed with a slight whitish down beneath. *Flowers* small, yellowish; their tube dotted with red. The *follicles* are ovate, deflexed, an inch long, covered with crowded soft tubercles. *Aublet*. We have seen no specimen. The author mentions no pulp in the seed-vessels.

6. *T. grandiflora*. Large-flowered Tabernæmontana. Linn. Mant. 53. Willd. n. 4. Jacq. Amer. 40. t. 31. Lamarck f. 2.—*Leaves* ovato-lanceolate, acute. Stem forked. Segments of the calyx unequal, very lax.—Found by Jacquin in woods at Carthage, but rarely, flowering from July to September. A *shrub* eight feet high, with forked divaricated, leafy *branches*. *Leaves* three or four inches long, tapering at each end, smooth and shining, on short stalks. *Flowers* large, inodorous, two or three together on a stalk, at the side of each uppermost fork of the branches. *Calyx* divided into five whitish, flat, ovate segments, very unequal in length, and loosely spreading, ill agreeing with the usual character of the genus; but the *fruit*, which is in this case much more important, is that of a *Tabernæmontana*. Its surface is smooth and green. *Jacquin*.

7. *T. cymosa*. Cymose Tabernæmontana. Linn. Mant. 53. Willd. n. 5. Jacq. Amer. 39. t. 181. f. 14.—*Leaves* ovato-lanceolate, acute. Cymes axillary, many-flowered. Stamens in the base of the tube. Follicles coloured, recurved, very obtuse.—Frequent in woods and bushy places at Carthage, flowering in July and August.—An elegant *shrub*, from six to fifteen feet in height. *Leaves* slightly wavy, half a foot long. *Cymes* large and handsome, convex,

dense, each of about forty dirty-white or reddish scentless *flowers*, the size of the first or second species. *Follicles* large, very blunt, red, spotted with brown; one of them generally abortive.

8. *T. obtusa*. Blunt-leaved Tabernæmontana.—*Leaves* obovate, obtuse. Panicles terminal, aggregate, forked, level-topped, many-flowered.—Gathered by Commerçon, in the isle of Bourbon. The *leaves* are three or four inches long, flat, smooth and shining, with fine close transverse veins; very obtuse, and often emarginate at the extremity; tapering at the base into a *footstalk* about an inch in length. *Panicles* three, in our specimen, at the end of the branch, on stalks, nearly equal to the adjoining leaves, repeatedly forked, consisting of numerous yellow *flowers*, smaller than in most of the foregoing. We know nothing of the *fruit*.

9. *T. amygdalifolia*. Almond-leaved Tabernæmontana. Jacq. Amer. 39. t. 181. f. 15.—*Leaves* oval-lanceolate, acute, smooth and shining. Anthers projecting out of the tube.—Frequent in woods and thickets at Carthage. A branching milky *shrub*, six feet high. *Leaves* flat, highly polished. *Flowers* but few on a stalk, white, powerfully scented. *Filaments* in the upper part of the tube, so that their *anthers* project above the orifice, in the form of a pointed cone. *Follicles* pointed, green and shining, resembling those of *T. citrifolia*, but scarcely half, or one-third, so large; their pulp orange. When this shrub begins to flower, it is mostly without leaves. *Jacquin*.

10. *T. discolor*. Two-coloured Tabernæmontana. Swartz Ind. Occ. 535. Willd. n. 7. Poiret in Lamarck n. 3.—*Leaves* elliptic-lanceolate, smooth, tapering at each end. Stalks two-flowered, terminal, thread-shaped.—Native of bushy places in Jamaica. *Swartz*. The *stem* is six feet high, with smooth, opposite *branches*, quadrangular when young, leafy at the ends. *Leaves* two or three inches long, stalked; dark green above; pale beneath. *Footstalks* bordered, about half an inch in length. *Flower-stalks* very slender, smooth, one and a half or two inches long, divided rather below the middle, and bearing two whitish or yellowish *flowers*, with one or two straggling *bractæas*. Tube of the *corolla* half an inch long; limb shorter. The *inflorescence* is terminal in Dr. Swartz's own specimen, as he describes it; and yet it is called axillary in the specific character; perhaps because it is, as in other species, closely attended by leaves.

11. *T. multiflora*. Many-flowered Tabernæmontana.—*Leaves* elliptic-lanceolate, smooth, pointed. Stalks lateral and terminal, many-flowered, thread-shaped, cymbose.—Gathered by the late Mr. Christopher Smith, in the isle of Banda. This much resembles the last in general habit, though the leaves are somewhat larger, with an oblong obtuse point, and more reticulated beneath. The *flowers* too are rather larger, and differ essentially in composing ample, repeatedly subdivided, cymbose *panicles*, about the ends of the branches, accompanied here and there by very minute, scattered, scale-like *bractæas*. The *corolla* seems flesh-coloured in the dried specimen, with long slender segments; its tube an inch long.

12. *T. undulata*. Wave-leaved Tabernæmontana. "Vahl Eclog. Amer. fasc. 2. 20." Poiret in Lamarck n. 5.—*Leaves* lanceolate-elliptical, pointed, undulated, smooth, nearly sessile. Branches forked. *Flowers* somewhat cymose. Follicles smooth.—Native of South America, and the island of Trinidad. The *leaves* are five or six inches in length, tipped with a long point; contracted at the base; bright green above; pale and yellowish beneath. *Flowers* three or four together, in small, solitary, axillary

TABERNÆMONTANA.

or terminal, cymose clusters. Tube an inch long. Follicles an inch and a half in length, reflexed, even, rather pointed. We have no knowledge of this species, or of the two following, but from the authors quoted.

13. *T. heterophylla*. Various-leaved Tabernæmontana. "Vahl Eclog. Amer. fasc. 2. 22." Poir. in Lam. n. 7. —"Leaves elliptic-lanceolate; partly somewhat heart-shaped, pointed, rather wavy, smooth. Branches forked. Flowers racemose."—Native of Cayenne. The leaves immediately under the forks of the branches are lanceolate, three or four inches long, and moderately stalked: the rest are sessile, much shorter, and almost heart-shaped. The flower-stalks are solitary, in the forks as well as at the summits of the branches, smooth and slender, each bearing from five to seven flowers, whose corolla is half an inch long, with some silky hairs about the mouth. Vahl.

14. *T. Pandacqui*. Pandacqui Tabernæmontana. Poir. in Lam. n. 8. (Pandacqui; Sonnerat Nouv. Guin. 49. t. 19.)—Leaves elliptic-lanceolate, smooth, with a blunt point. Panicles axillary, corymbose, many-flowered, half as long as the leaves.—Native of the Philippine islands, where it was found by Sonnerat. He says the natives of the isle of Luçon apply the milk of this shrub to their wounds. The stem is four or five feet high. Leaves two or three inches long, smooth, even, and quite entire, on short stalks. Flowers white; their tube an inch long; limb scarcely half that length. He did not see the fruit. The younger Linnæus most unaccountably referred this plant, in the Supplement, to *Chiococca racemosa*, with which it accords as little as can well be. It is now, on Jussieu's authority, removed to the present genus; and as he speaks decisively on the subject, Gen. Pl. 145, we presume he was acquainted with the follicles.

15. *T. persicariaefolia*. Knot-grass-leaved Tabernæmontana. Jacq. Coll. v. 4. 139. Ic. Rar. t. 320. Willd. n. 8. Poir. in Lam. n. 9.—Leaves lanceolate, smooth, tapering at each end. Corymbs from the forks of the branches, in pairs, divided.—Native of the island of Mauritius. The stem is shrubby, erect, slender, repeatedly branched. Leaves four or five inches long, more or less tapering at the end, dark green, shining, with a white rib and veins; their margin slightly undulated. Footstalks hardly an inch in length. Flowers yellowish-white; their tube and limb each measuring nearly an inch. We have from Commerçon a specimen collected in the island above-mentioned, which answers to Jacquuin's description and figure, except the leaves being less elongated; but it can scarcely be more than a variety. Another from the isle of Bourbon would appear to be the same plant, but its inflorescence is lateral, from the bosoms of the leaves, not from the forks of the branches. Still we dare not describe this as a separate species.

16. *T. neriifolia*. Oleander-leaved Tabernæmontana. "Vahl Eclog. Amer. fasc. 2. 21." Poir. in Lam. n. 10.—Leaves lanceolate, smooth, veinless, acute at each end. Clusters axillary, solitary, of few flowers. Limb of the corolla downy about the mouth. Stamens prominent.—Native of Porto-Rico. Allied to the last. Leaves two or three inches long, scarcely wavy at the margin; paler beneath; marked with a few fine lateral distant ribs. Footstalks half an inch long. Clusters twice the length of the footstalks, each of three or four flowers, with a small, linear, deciduous bractea to each of their short partial stalks. Corolla about half an inch long, with wedge-shaped segments, a little downy on their inner side towards the base. The stamens, (we presume the anthers only,) project out of the tube. Vahl. The specific character given by this author

VOL. XXXV.

being quite insufficient, we have ventured to enlarge it from his description, without seeing the plant.

17. *T. mauritiana*. Brittle Tabernæmontana. Poir. in Lam. n. 11.—Leaves ovate, obtuse, membranous; scarcely downy beneath. Clusters axillary, of few flowers. Branches with brittle joints.—Gathered by Commerçon in the island of Mauritius, and by Sonnerat in the East Indies. We find no specimen in our collection answerable to Poir. description. He says the plant is remarkable for its woody, cylindrical, striated, smooth branches being jointed at the insertion of the leaves, and very brittle at those joints; bearing very small, oval, whitish tubercles. Leaves thin, membranous, oval, obtuse, rounded at each end, entire, a little wavy at the edges, three or four inches long, and two and a half wide; green and rather shining above; paler beneath, and very soft to the touch, but hardly pubescent; having one stout yellowish mid-rib, with fine parallel transverse veins. Footstalks thick, from six to eight lines in length. Clusters short and nearly simple, towards the ends of the branches, a little drooping. Corolla yellowish-white; its tube three or four lines long; limb short and obtuse. Fruit not examined. Poir.

18. *T. Sananho*. Sananho Tabernæmontana. "Ruiz and Pavon. Fl. Peruv. v. 2. 22. t. 144." Poir. in Lam. n. 12.—Leaves oblong, pointed, smooth, somewhat wavy. Corymbs with four or five branches. Bracteas inversely heart-shaped. Follicles roundish-obovate, pointed.—Native of the extensive forests of Peru, flowering in August and September. A shrub twelve or fifteen feet high, or more, with smooth cylindrical branches. Leaves six or eight inches long, stalked, shining, somewhat veiny. Flowers yellowish-white, lateral and terminal, from fifteen to twenty in each corymb. Corolla large, with a very long angular tube. Follicles the size of an apricot, of a dirty white, containing many brown striated seeds lodged in pulp. Poir.

19. *T. arcuata*. Curve-fruited Tabernæmontana. "Ruiz and Pavon Fl. Peruv. v. 2. 22. t. 143." Poir. in Lam. n. 15.—Leaves obovate-oblong, pointed, entire, on short stalks. Corymbs axillary, ternate, many-flowered. Follicles recurved.—Common in the great forests of Peru, about Pozuzo, flowering in November and December. A tree, thirty or forty feet high, discharging, when wounded, a very copious milky juice, which hardens in the air into a gum-resin of a brown hue. The branches form an ample leafy head, and are forked, pale, slightly compressed. Leaves eight or nine inches long, on short, rather twisted stalks. Flowers yellowish-white, with small, oval, pointed bracteas. Follicles oblong, thick, three inches in length, reddish, full of red wrinkled seeds, in a crimson pulp.

20. *T. fasciculata*. Cluster-flowered Tabernæmontana. Poir. in Lam. n. 14.—Leaves oval-lanceolate, pointed, smooth, ribbed. Clusters axillary, somewhat umbellate, many-flowered. Segments of the corolla linear. Branches jointed.—Native of Cayenne. Seen by Poir. in Lamarck's herbarium. He describes the branches as very brittle at the insertion of the leaves, which are stalked, two or three inches long, an inch or more in width, rather obtuse, though pointed; shining above, reddish beneath. Flowers plentiful about the ends of the branches, in short, tufted, inclined corymbs, whose ramifications are somewhat forked and jointed, with little short deciduous bracteas. Tube of the corolla but two or three lines long; limb in five narrow, linear, obtuse segments. Fruit unknown. If it should prove muricated, Poir. thinks this species may not differ much from *T. echinata* of Aublet. See species 5.

C

21 T.

TABERNÆMONTANA.

21. *T. coronaria*. Garland Tabernæmontana. Ait. n. 3. Roxburgh MSS. (*Nerium coronarium*; Willd. Sp. Pl. v. 1. 1236. Jacq. Ic. Rar. t. 52. *N. divaricatum*; Linn. Sp. Pl. 306. Willd. *ibid.* *Jasminum zeylanicum*, folio oblongo, flore albo pleno odoratissimo; Burm. Zeyl. 129. t. 59. Nandi-ervatam; Rheede Hort. Malab. v. 2. 105. 107. t. 54, 55.)—Leaves elliptical, pointed, smooth. Stalks forked, corymbose, from the forks of the branches, as long as the leaves.—Native of the East Indies, in a sandy soil, flowering two or three times in a year. It is said to have been introduced into the English stoves by the late Mr. Gordon, in 1770. This plant blooms at various seasons, and is ornamental as well as fragrant, though inferior in both respects to the *Gardenia florida*, with which some of its synonyms have been confounded. Its genus is now more correctly determined in the second edition of Hort. Kew. than in the first; but a faulty specific character still remains, taken (as it seems) from Jacquin's plate, which exhibits a weak imperfect specimen. The stem is shrubby, bushy, smooth, three or four feet high, with copious forked spreading branches. Leaves two or two and a half inches long, paler beneath, on channelled footstalks half an inch in length. The corymbs, in various wild or cultivated, single or double-flowered, specimens before us, consist of from three to six cream-coloured flowers, and are elevated on a stalk, an inch and a half long, always solitary, from the forks of the branches. The single corolla has a rather slender tube, an inch long, with broad segments to the limb, about the same length; but in a double state both parts are much enlarged and thickened.

Mr. Brown has determined the *Nerium divaricatum* of Linnæus, erroneously marked as biennial, to be the same plant with the above. We shall now proceed to enumerate three new species from his *Prodromus*.

22. *T. orientalis*. Smooth Indian Tabernæmontana. Brown n. 1.—“Leaves lanceolate-oblong, pointed, very smooth, as well as the branches. Cymes repeatedly compound, smooth. Bractæas awl-shaped, not soon deciduous.”—Gathered in the tropical part of New Holland, by Mr. Brown, who suspects the *Curutu-Pala*, Hort. Malab. 83. t. 46, cited by Linnæus for his *T. alternifolia*, see our 25th species, may belong to the present plant, the leaves being erroneously represented as alternate.

23. *T. pubescens*. Downy New Holland Tabernæmontana. Br. n. 2.—“Leaves elliptic-oblong, somewhat pointed, downy beneath like the young branches. Branches of the cymes erect, hairy as well as the calyx. Bractæas very minute, deciduous.”—Native of the tropical part of New Holland. *M. R. Brown*.

24. *T. ebraeata*. Naked-flowered Tabernæmontana. Br. n. 3.—“Leaves somewhat elliptical, downy as well as the cymes. Branches and flower-stalks spreading. Bractæas none.”—Found by Mr. Brown in the same country as the two last. We have seen no specimens of any of these three species.

25. *T. alternifolia*. Alternate-leaved Tabernæmontana. Linn. Sp. Pl. 308. Willd. n. 10. Poir. in Lam. n. 20. (*Curutu-Pala*; Rheede Hort. Malab. v. 1. 83. t. 46.)—Leaves scattered, ovato-lanceolate.—Native of sandy ground on the coast of Malabar, flowering all the year, but especially in the rainy season. A small tree, from six to twelve feet high, a foot in diameter. The leaves are three or four inches long, pointed, on short thick footstalks, more or less alternate, or dispersed, according to the figure, which is our only authority for that character. Panicles lateral or terminal, corymbose, drooping, of about nine white fra-

grant flowers, whose tube is near two inches long, the limb dilated and notched, very much twisted. Follicles tawny, ovate, an inch long, with a recurved point. Linnæus depended solely on the Hortus Malabaricus for this species, of which he had no specimen. The circumstance of the alternate leaves, unexampled in any known *Tabernæmontana*, has excited a reasonable suspicion of error. See our 22d species.

26. *T. bufalina*. Buffalo-horned Tabernæmontana. Loureir. Cochinch. 117. (*Capficum sylvestre*; Rumph. Amboin. v. 4. 133. t. 67.)—Leaves lanceolate, smooth. Stalks lateral, in pairs, single-flowered, pendulous.—Native of moist shady vallies in Amboina, and of bushy places in Cochinchina, where it is called *Cây sùng trâu*. A shrub five feet high, branched, nearly erect. Leaves opposite, from five to eight inches in length, ovato-lanceolate, shining, entire. Flowers white, on long simple stalks. Tube long and slender, inflated at the base. Follicles rather long, pointed, swelling, smooth, with an unequal surface. Seeds oblong, angular, imbedded in red pulp. The fruit in Rumphius's plate is more like the following. *Loureiro*.

27. *T. bovina*. Bull-horned Tabernæmontana. Loureir. Cochinch. 118. (*Cây sùng bò* of the Cochinchinese.)—Leaves lanceolate, smooth. Stalks axillary, solitary, nearly erect, about five-flowered.—Native of the plains of Cochinchina. A shrub four feet high, with drooping branches. Leaves opposite, entire. Flowers white. Follicles short, recurved, tumid, pointed, even in the surface. Seeds roundish, angular, lodged in red pulp.

Loureiro, from whose work and that of Rumphius all our knowledge of the two last species is derived, attributes to them an emollient and relaxing quality. Their viscid milky juice is said gently to draw out thorns from the flesh.

The herbaceous plants, supposed by Linnæus to belong to this genus, constitute, as we have already said, and as Linnæus himself originally thought, a very distinct one, of which we shall now treat by the name of *Amsonia*. We can give no positive account of the meaning or origin of this name, except that its author, according to Miller, was Clayton. Linnæus, in his own copy of Gronovius's *Flora Virginica*, ed. 1. p. 26, has written *Amsonia*, as a generic name, to what Clayton took for a species of *Nerium*, and has subjoined also in manuscript the characters of the follicles and seeds. This plant, in the second edition of Sp. Pl. is the *Tabernæmontana Amsonia*; and so it remained, till Mr. Walter restored it to rank as a genus; but without throwing any light upon the name. A similar obscurity envelopes the nearly similar name of *AMASONIA*, (see that article,) which is reported in the Supplementum of Linnæus to be dedicated to the honour of Amason, a traveller in America, whom M. De Theis has baptized Thomas. But we have never been able to learn any tidings of such a person. Whether *Amsonia*, being an error in orthography for *Ansonia*, may have been designed to commemorate the great lord Anson, who brought home a new esculent pea, and deserved botanical commemoration as much as any other eminent navigator not a professed botanist; and whether *Amasonia* be a still further corruption of the same name, we must leave in doubt. We have only to observe, that if both these names should prove to have the same origin, or be thought, as they certainly are, too nearly alike, the former, *Amsonia*, ought to be retained in preference to the latter, which is of much later date.

AMSONIA. Walter Carolin. 98. Michaux Boreali-Amer. v. 1. 121. Pursh 184. Ait. Hort. Kew. v. 2. 72. —Clafs

TABERNÆMONTANA.

—Class and order, *Pentandria Monogynia*. Nat. Ord. *Convolv.*, Linn. *Apocineæ*, Juss. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, in five deep, acute, triangular, spreading segments, permanent. *Cor.* of one petal, funnel-shaped; tube many times longer than the calyx, gradually swelling upwards, hairy in the throat; limb about as long as the tube, in five deep, lanceolate, variously spreading, oblique segments. Nectary of five minute glands, surrounding the germen. *Stam.* Filaments five, small, inserted into the upper part of the tube; anthers erect, arrow-shaped, converging, within the tube. *Pist.* Germens two, simple, ovate; style solitary, central, thread-shaped, about as long as the tube; stigma oblong, obtuse. *Peric.* Follicles two, erect, long, cylindrical, pointed, destitute of internal pulp. *Seeds* numerous, pointed, rough, naked, abrupt and oblique at the point.

Eff. Ch. Corolla funnel-shaped; its limb in five deep oblique segments. Anthers arrow-shaped, within the tube. Follicles two, cylindrical, erect. Seeds cylindrical, naked.

1. *A. latifolia*. Broad-leaved Amfonia. Michaux n. 1. Pursh n. 1. Ait. n. 1. (Tabernæmontana Amfonia; Linn. Sp. Pl. 308. Willd. Sp. Pl. v. 1. 1246. *Apocynum virginianum erectum, alternis asclepiadis foliis, floribus pallide cæruleis, radice crassa*; Pluk. *Almag.* 35. *Phyt.* t. 115. f. 3.)—Stem smooth. Leaves ovato-lanceolate; slightly hairy beneath. Panicle taller than the lateral branches. Limb of the corolla ascending.—Native of shady wet woods in Carolina, flowering in May. *Pursh.* Cultivated by Miller in 1759, and hardy in our climate. The root is fleshy, perennial. *Stem* herbaceous, erect, a foot high, round, leafy, nearly or quite smooth, terminated by a compound smooth panicle of greyish-blue scentless flowers, and bearing two or three alternate leafy branches, which do not rise above the panicle till the flowers are past. *Corolla* very hairy about the mouth; its tube pale, nearly half an inch long. The leaves are all alternate, on short footstalks, entire, pointed, two or three inches in length, and one in breadth; paler beneath, and minutely hairy about the edges and veins.

2. *A. tristis*. Brownish-flowered Amfonia.—Stem smooth; its branches overtopping the panicle. Leaves ovate; slightly hairy beneath. Limb of the corolla reflexed.—Brought from North America, by Mr. Lyon. We received a specimen in flower, in June 1808, from Mr. Vere's garden, at Knightsbridge. This is rather taller than the foregoing, and distinguished by its leafy lateral branches rising high above the panicle. The flowers are smaller, of a dingy brown hue; the segments of their limb strongly reflexed, at least in fading. *Follicles* smooth, cylindrical. Perhaps Mr. Walter might have this species in view when he attributes tawny flowers (*flores fulvi*) to his *A. ciliata*, our 4th species.

3. *A. salicifolia*. Willow-leaved Amfonia. Pursh n. 2.—“Stem smooth. Leaves linear-lanceolate, acute at each end, very smooth.”—Gathered by Mr. Lyon in Carolina and Georgia, flowering in May. *Flowers* the same as the first species, more abundant. *Pursh.*

4. *A. angustifolia*. Narrow-leaved Amfonia. Michaux n. 2. Pursh n. 3. Ait. n. 2. Ventenat. Choix. t. 29. (*A. ciliata*; Walter n. 2. Tabernæmontana angustifolia; Willd. Sp. Pl. v. 1. 1247.)—Stem downy. Leaves linear, erect, fringed.—In sandy barren ground of Carolina and Georgia, flowering in May and June. *Flowers* of the same disposition and colour as in *A. latifolia* and *salicifolia*. *Pursh.* This species is said to have been introduced into the English gardens, in 1774, by the late Mr. James Gordon. Its copious narrow leaves are glaucous beneath, and smooth, except at the edges, where they are fringed with long soft

hairs, such as clothe the stem. Ventenat says the upper ones are quite smooth, but this is not the case in our specimen. The teeth of the calyx are sometimes tipped with a tuft of hairs. Walter says the flowers are tawny; others describe them, as we find them, like those of *A. latifolia*, blue, with a pale, or somewhat tawny, tube. The follicles of all the species, as far as we have seen, are slender, cylindrical, and smooth, about two inches long.

TABERNÆMONTANA, in *Gardening*, contains plants of the woody, exotic, and hardy perennial kinds, among which the species chiefly cultivated for garden purposes are, the citron-leaved tabernæmontana (*T. citrifolia*); the laurel-leaved tabernæmontana (*T. laurifolia*); the Virginian tabernæmontana (*T. amfonia*); and the narrow-leaved tabernæmontana (*T. angustifolia*).

These are all plants of the more tender and delicate kind, but more especially the two first sorts, which require the constant aid of artificial heat in this climate.

Method of Culture.—All these plants may be increased by seeds, which must be procured from the countries where the plants grow naturally, and be sown early in the spring on a hot-bed; and when the plants are come up, and fit to remove, be carefully planted out into small pots filled with light rich earth, and then plunged into a hot-bed of tanners' bark, being careful to shade them in the heat of the day, until they have taken new root; after which they should have free air admitted to them every day when the weather is warm; but on cold nights have the glasses of the hot-bed covered with mats every evening, soon after the sun goes off from the bed: they must be often refreshed with water, but not in large quantities, especially while they are young, as they are full of a milky juice, and are subject to rot with much moisture: they may remain during the summer season in the hot-bed, by stirring up the tan to renew the heat when it wants it, and a little new tan being added; but when the nights begin to be cold, the plants should be removed, and plunged into the bark-bed in the stove, where, during the winter season, they must be kept in a moderate degree of warmth, and in cold weather have but little water given them: they should constantly remain in the stove, where, in warm weather, they may have free air admitted to them by opening the glasses, but in cold weather be kept in a warm state. With this management they thrive and produce flowers; and, as their leaves are always green, make a pleasant diversity among other tender exotic plants: they may be increased likewise by cuttings in the summer season, which should be cut off from the old plants, and laid to dry in the stove five or six days before they are planted, that the wounded parts may heal over: these should then be planted in pots filled with fresh light earth, and be plunged into the hot-bed of tanners' bark, and closely covered with a hand-glass, shading them from the sun in the middle of the day in hot weather, refreshing them now and then with a little water: when they have taken root, they may be planted out into separate pots, and be treated in the same manner as those raised from seeds are recommended to be.

It may be noticed, that the third and fourth sorts are capable of living in the open air here, provided they are planted in a warm situation: they love a light soil, rather moist than otherwise; of course, when planted in dry ground, they should be frequently watered in dry weather. They are best increased by offsets from the roots, which should be planted out in the autumnal season.

Among these, the two first sorts afford variety in the stove, and the latter sorts in this as well as the borders in mild climates.

TABERNÆMONTANUS, JAMES THEODORE, in *Biography*, a physician and botanist, was born at Berg-Zabern, in Alsace, and having practised as an apothecary, and acquired some knowledge of botany, went to France, where he took the degree of M.D. Advancing in his profession, he became first physician to the Elector-Palatine, the bishop of Spire, and other persons of rank. He died at Heidelberg, whither he had removed from Worms, in the year 1590. Apprehending that Providence had furnished every country with remedies suitable to its diseases, he confided much in the efficacy of herbs; and particularly in the powder of mugwort. His German Herbal consists of three volumes, published separately in the years 1558, 1590, and 1592, and containing figures, copied either by himself or others from nature. This work was well received, and has been often reprinted. He also published in German a treatise on baths and mineral waters. Haller. Eloy. Gen. Biog.

TABERNAS, in *Geography*, a town of Spain, in the province of Grenada; 15 miles N.N.E. of Almeria.

TABERNE, a town of Kurdistan; 50 miles E.S.E. of Kerkuk.

TABES, in *Ancient Geography*, a town of Asia, in the mountains of Parætacène, upon the frontiers of Persia and Babylonia. Strabo and Quintus Curtius.

TABES, in *Medicine*, a wasting or consumption of the body, accompanied with hectic fever. The distinction which nosologists have made between tabes and atrophy, is founded on the presence of hectic fever in the former, and its absence in the latter form of disease. Such a definition of tabes, however, would comprehend phthisis, a term which is generally restricted to that species of consumption which has its origin in diseases of the lungs. (See CONSUMPTION.) The ground of the distinction between tabes and atrophy, has already been fully discussed under the head of ATROPHY: and the train of symptoms constituting the fever that accompanies tabes, is sufficiently detailed under the article *Hectic Fever*. Dr. Cullen has enumerated three species of tabes; the first, which he calls the *purulent*, arising from suppuration, either of an internal or external part, and the seat of which may be various, according to the organ originally diseased; the second, the *serofulous*, being the consequence of serofula affecting different parts, but more especially the mesenteric glands; and the third, the *venenata*, proceeding from the operation of a poisonous substance received into the body. The other affections which had been classed by Sauvages under tabes, such as the tabes dorsalis, nutriceum, sudatoria, a sanguifluxu, syphilitica, and a hydrope, are referred by Dr. Cullen to the genus ATROPHY; which see.

TABES Dorsalis, a species of consumption arising from the excessive evacuation of semen: its symptoms and treatment are detailed under ATROPHY.

TABES Mesenterica, or mesenteric consumption, is a disease that more particularly affects children, and arises from obstruction and enlargement of the mesenteric glands. Children are liable to its attacks from the age of three or four years, and become less so when they have attained that of eight or ten, unless they are of serofulous habits, in which case the disease may supervene at a much later period. Its relation to serofula is clearly marked, from its more frequent occurrence in families where this disease is hereditary: but it may, at the same time, arise independently of that affection, from a great variety of causes. It may be induced by any protracted disease of infancy producing much constitutional disturbance, and more especially by such as are attended with disorder of the functions of the alimentary canal. It may often be traced to improper treatment, or unwholesome food; to long-continued irritation from teething; to

the suppression of eruptions, or the incautious stopping of diarrhœa; and sometimes appears to be the consequence of exanthematous fevers, as the measles, small-pox, or scarlatina. The presence of worms in the intestines, has very frequently been accused of laying the foundation of this disease: but it may be questioned, whether they are not more generally the consequence than the cause of derangement in the primæ viæ attendant on this disorder.

The symptoms which attend the early stages of this affection, and before the enlargement of the glands has become sensible, are similar to those which accompany many of the diseases of the alimentary canal, more especially those produced by worms, and can hardly be distinguished from them. Indigestion occurs in various degrees, denoted by the usual signs, such as acid eructations, fetid breath, great irregularity in the action of the bowels, and in the appearance of the stools; occasional fever, occurring, however, less in regular paroxysms than happens in the remitting fever of infants, but giving a hectic flush to the cheeks, which, when the fever has subsided, are of a pallid hue. The appetite is extremely irregular; sometimes it is nearly gone, at other times it is voracious, and attended with a sense of craving, unless speedily satisfied. The symptom which particularly characterises this disease, when occurring in conjunction with those above stated, is shooting pains in the abdomen, varying considerably, both in their seat and their intensity, at different times. These pains, though felt more or less every day, occur only at intervals, and frequently, after a longer intermission than usual, they return with more severity than before.

The belly now begins to swell and to grow hard, while, at the same time, the limbs and countenance are emaciated: the strength and spirits decline; the hectic fever is more and more distinctly marked, and exerts its usual undermining influence on the constitution. Cough frequently attends this complaint in its latter stages, and the symptoms become blended with those of true pulmonary consumption. The disease of the mesenteric glands is often, indeed, found, on dissection, to have extended to other viscera, and more especially to the lungs: and tubercles, and even purulent matter, are not unfrequently found in them, although the symptoms during life did not particularly indicate any affection of these organs. The mesenteric glands themselves exhibit different appearances, according to the progress which the disease has made: in the early stages they are enlarged in their size, and are somewhat softer to the touch than in a natural state: but upon being cut into, do not exhibit any sensible deviation from their natural structure. If the patient, however, has not already sunk from the exhaustion of the constitutional affection, the disease proceeds to suppuration, the pus being intermixed with the white, soft, and curdy matter which is so peculiar to serofula.

Mesenteric consumption is a disease of frequent occurrence, and when it has proceeded a certain length, is almost invariably fatal. Yet we find, in some rare instances, that the powers of the constitution are sometimes called forth in an extraordinary manner under the most unpromising circumstances, and the disease recovered from. In the early periods of life, indeed, we see nature abounding in resources, which a more mature age cannot supply: and there is, to use the language of the late Dr. Gregory, "a greater luxuriance of life and health in infancy than at any other period. Infants, it is acknowledged, are more delicately sensible to injury than those advanced in life; but to compensate this, their fibres and vessels are more capable of distention, their whole system is more flexible, their fluids are less acid, and less disposed to putrescence; they bear all evacuations more easily,

easily, except that of blood; and, which is an important circumstance in their favour, they never suffer from the terrors of a distracted imagination. Their spirits are lively and equal; they quickly forget their past sufferings, and never anticipate the future. In consequence of these advantages, children recover from diseases, under such unfavourable circumstances as are never survived by adults. If they waste more quickly under sickness, their recovery from it is quick in proportion, and generally more complete than in older people; as diseases seldom leave those baneful effects on their constitutions so frequent in adults. In short, a physician ought scarce ever to despair of a child's life, while it continues to breathe."

The plan of treatment to be pursued in this disease, must be founded very much on the same principles as that of scrofula in general, modified, however, in some degree, by its peculiar seat, and by the functions of the parts affected. It is chiefly in the earlier stages that we can expect much efficacy from an alterative course of remedies in the removal of the glandular obstructions. As there is often much ambiguity between the symptoms of this disease and those occasioned by the presence of the round worm in the intestines, we should first satisfy ourselves that this is not the sole cause of the disorder. In both diseases there is a tumid belly, and emaciated extremities: so that the chief ground of distinction is derived from the effect of strong purgatives, which bring away worms in the one case, and none in the other. It is observed by Dr. Baillie, that startings and grinding of the teeth during sleep, occur very commonly in worms, but are rarely observed as symptoms of scrofulous enlargement of the mesenteric glands. Some discrimination, likewise, between the two diseases, may sometimes be derived from examining strictly into the nature of the constitution. If decided marks of scrofula shew themselves in an external part of the body, they will lead a practitioner more satisfactorily to the opinion, that the mesenteric glands are also affected with the same disease.

The principal alterative remedy on which any dependence can be placed is mercury, particularly in the form of calomel; half a grain, or a grain of which, may be given two or three times a week, in conjunction with, or succeeded by, some mild purgative. On the intermediate days, small doses of alkalies, with rhubarb, may be exhibited. Great attention should, at all times, be paid to the state of the bowels, which should be kept freely open: while the acrimony of their contents should be counteracted by absorbents, such as magnesia, when there is no diarrhoea, or by prepared chalk, or gentle astringents, in small doses, when this latter state prevails. For the removal of fever, the same means are to be employed as have already been pointed out when treating of the infantile remitting fever, under the head of *Diseases of INFANTS*. The calomel, combined with purgatives, may be continued, for several weeks, till a favourable change has been effected in the size and hardness of the belly. The milder vegetable tonics, such as chamomile, or cascarrilla, may then be tried, and according as the constitution will bear them, preparations of iron should be given, in order to strengthen the digestive organs, and the system in general. Together with these means, every circumstance which can contribute to general health should be attended to. Pure air, regular exercise, gentle frictions of the body and limbs, an easy dress, frequent washing of the whole body with soap and warm water in young children, or the cold bath in older children, and especially a light and nutritious diet, with such mild aromatics as may assist digestion, are some of the principal and most effectual means of securing the ground that has been gained, and of preventing a return, as well as

guarding against an attack, of the disease. For greater details on these points, see *Diseases of INFANTS*, and *SCROFULA*.

TABEYRO, in *Geography*, a town of Spain, in Galicia; 5 miles S.E. of St. Jago.

TABIANA, in *Ancient Geography*, an island of the Persian gulf, near and west of the isle of Sophthe, and over against the promontory of Taocce.

TABIANA, in *Geography*, a town of the duchy of Parma; 13 miles W. of Parma.

TABIDIUM, in *Ancient Geography*, a town in the interior of Africa, towards the source of the river Bagrada.

TABILLOLA, in *Geography*, a town on the south coast of the island of Machian. N. lat. $0^{\circ} 13'$. E. long. $127^{\circ} 21'$.

TABINSK, a town of Russia, in the government of Upha, on the Bielaia; 40 miles S. of Upha. N. lat. 54° . E. long. $56^{\circ} 14'$.

TABLADA, a town of South America, in the province of Carthagena; 80 miles S. of Mompox.

TABLANÄTZ, a town of Istria; 24 miles N.E. of Pedena.

TABLAS, one of the Philippine islands, about 25 miles long from north to south, but narrow and intersected by a deep bay on the east and west coasts. N. lat. $12^{\circ} 30'$. E. long. $121^{\circ} 40'$.

TABLATURE, in *Anatomy*, a division or parting of the skull into two tables.

TABLATURE, *Tablatura*, in *Music*, in general, is when to express the sounds or notes of a composition, we use letters of the alphabet, or cyphers, or any other characters not used in the modern music.

TABLATURE, in its stricter sense, is the manner of writing a piece for the lute, theorbo, guitarre, bass viol, or the like; which is done by writing on several parallel lines (each of which represents a string of the instrument) certain letters of the alphabet, referring to the frets on the neck of the instrument: of which A marks, that the string is to be struck open, *i. e.* without putting the finger of the left hand on the head; B shews, that one of the fingers is to be put on the first stop; C, on the second; D, on the third, &c.

The time of the notes is signified by marks over the letters of a hooked form, that answer to the minim, crotchet, quaver, &c. in the French tablature; but the Italians and Spaniards, till of late years, made use of figures instead of letters.

The tablature of the lute is usually written in letters of the alphabet, and that of the harpsichord in the common notes.

TABLE, TABULA, a moveable; usually made of wood, or stone supported on pillars, or the like; for the commodious reception of things placed upon it.

Moses made a table, in the tabernacle, for laying the shew-bread upon, described by Philo Judæus as two cubits long, one broad, and one and a half high.

Among Christians, the *table*, or *Lord's table*, signifies the sacrament of the Lord's supper. See COMMUNION.

TABLE, *Round, Knights of the Round Table*, a military order supposed to have been instituted by Arthur, the first king of the Britons, in the year 516.

They are said to have been twenty-four in number; all selected from among the bravest of the nation.

The round table, which gave them their title, was an invention of that prince, to avoid disputes about the upper and lower end, and to take away all emulation as to places.

Lesley assures us, he saw the table at Winchester; at least, he says, if he might believe the keepers of it, who still shew

shew it with great solemnity. He adds, that the names of a great number of knights, written around it, seemed to confirm the truth of the tradition.

Larrey also, and several other authors, make no scruple to relate this fable of knighthood as matter of history: but that it is a fable, is certain; F. Papebroch having shewn, that there was no such thing as an order of knights before the sixth century.

Camden also observes, that the table at Winchester is of a structure much more modern than the sixth century. It is to be added, that Arthur himself is esteemed by many no more than a fabulous prince.

An excellent historian observes, that Arthur was undoubtedly a great general, though his actions have given occasion to innumerable fables; and though the institution of the "Knights of the Round Table" has served as a foundation for many fabulous relations, it is not to be deemed altogether chimerical. For where is the improbability that Arthur should institute an order of knighthood in Britain, when we learn from the letters of Cassiodorus, that Theodoric, king of the Ostrogoths, instituted one in Italy in the same century. Rapin's Hist. of Eng. vol. i. p. 39. fol.

However, others have supposed that the round table was not any military order, but rather a kind of just, or military exercise, between two persons armed with lances. Several authors say that Arthur, duke of Bretagne, renewed it. See Matthew Paris, the abbot Justiniani, and F. Helyot.

Paulus Jovius says, it was under the empire of Frederic Barbarossa that the knights of the Round Table first began to be talked of; others attribute their origin to the factions of the Guelphs and Gibellins. King Edward I. built a house called the Round Table, the court of which was two hundred feet in diameter. Du-Cange Gloss. *Tabula*.

TABLE, in *Architecture*, a smooth, simple member, or ornament, of various forms, but most usually in that of a long square. See **PLATBAND**.

TABLE, *Projecting*, is such a one as stands out from the naked of the wall, pedestal, or other matter which it adorns.

TABLE, *Raked*. See **RAKING-Table**.

TABLE, *Raised*, an embossment in a frontispiece, for the putting an inscription, or other ornament, in sculpture. This is what M. Perrault understands by *abaqus* in Vitruvius.

TABLE, *Crowned*, that covered with a cornice, and in which is cut a basso-relievo, or a piece of black marble incrustated, for an inscription.

TABLE, *Rusticated*, that which is picked, and whose surface seems rough, as in grottos, &c. See **RUSTICS**.

TABLE, *Water*. See **WATER-Table**.

TABLE, *Plain*, a surveying instrument. See **PLAIN Table**.

TABLE, in *Perspective*, denotes a plain surface, supposed to be transparent, and perpendicular to the horizon.

It is always imagined to be placed at a certain distance between the eye and objects, for the objects to be represented thereon by means of visual rays passing from every point thereof, through the table to the eye.

Whence it is also called *perspective plane*. See **PERSPECTIVE**.

TABLE, in *Anatomy*. The cranium is said to be composed of two tables, or laminae; *i. e.* it is double, as if it consisted of two bones laid one over another. See **SKULL**.

TABLE of *Pythagoras*, called also *multiplication-table*, is a square formed of an hundred or more lesser squares, or cells, containing the products of the several digits, or simple numbers, multiplied by each other. See this table under **MULTIPLICATION**.

TABLES, *Laws of the Twelve*, were the first set of laws of the Romans; thus called, either because the Romans then wrote with a style on thin wooden tables, covered with wax; or, rather, because they were engraved on tables, or plates of copper, to be exposed in the most noted part of the public forum. Wood, brags, or ivory, might be successively employed.

After the expulsion of the kings, as the Romans were then without any fixed or certain system of law; at least, had none ample enough to take in the various cases that might fall between particular persons; it was resolved to adopt the best and wisest laws of the Greeks.

One Hermodorus, to whom a statue was erected in the forum, was first appointed to translate them; and the decemviri afterwards compiled and reduced them into ten tables. After immense care and application, they were, at length, enacted and confirmed by the senate, and an assembly of the people, in the year of Rome 303.

The following year they found some things wanting therein, which they supplied from the laws of the former kings of Rome, and from certain customs, which long use had authorized: all these, being engraven on two other tables, made the *law of the twelve tables*, so famous in the Roman jurisprudence; and the source and foundation of civil or Roman law. See **CIVIL Law**.

The laws of the twelve tables were also called *decemviral laws*, from the officers entrusted with the composing them. See **DECENVIRI**.

These laws of the decemviri were dictated by the rigid and jealous spirit of an aristocracy, which had yielded with reluctance to the just demands of the people. But the substance of the twelve tables was adapted to the state of the city; and the Romans must have emerged from barbarism, since they were capable of studying and embracing the institutions of their more enlightened neighbours. Mr. Gibbon suggests, that a motive of national pride induced Livy and Dionysius to believe, that deputies from Rome visited Athens under the wise and splendid administration of Pericles, and that the laws of Solon were transfused into the twelve tables. If such an embassy, says the historian of the Roman empire, had indeed been received from the barbarians of Hesperia, the Roman name would have been familiar to the Greeks before the reign of Alexander, and the faintest evidence would have been explored and celebrated by the curiosity of succeeding times. But the Athenian monuments are silent; nor will it seem credible that the patricians should undertake a long and perilous navigation, to copy the purest model of a democracy. In the comparison of the tables of Solon with those of the decemvirs, some copied resemblance may be found; some rules which nature and reason have revealed to every society; some proofs of a common descent from Egypt or Phoenicia. But in all the great lines of public and private jurisprudence, the legislators of Rome and Athens appear to be strangers or adverse to each other.

Whatever, as the same historian proceeds, might be the origin or the merit of the twelve tables, they obtained among the Romans that blind and partial reverence which the lawyers of every country delight to bestow on their municipal institutions. The study is recommended by Cicero as equally pleasant and instructive. "How admirable," says the Roman orator, with honest or affected prejudice, "is the wisdom of our ancestors! We alone are the masters of civil prudence; and our superiority is the more conspicuous, if we deign to cast our eyes on the rude and almost ridiculous jurisprudence of Dracon, of Solon, and of Lycurgus."

The twelve tables were committed to the memory of the young, and the mediation of the old; they were transcribed and illustrated with learned diligence; they had escaped the flames of the Gauls, they subsisted in the age of Justinian, and their subsequent loss has been imperfectly restored by the labours of modern critics.

It is a great pity this system of law should have perished through the injuries of time: we have now nothing of it, but a few fragments dispersed in divers authors. J. Gothofred has collected them together, and we have them in Rufinus, and some other authors. The Latin is very old and barbarous, and remarkably obscure. See *CIVIL LAW*.

Although these venerable monuments of antiquity were considered as the rule of right and the fountain of justice, they were overwhelmed by the weight and variety of new laws, which, at the end of five centuries, became a grievance more intolerable than the vices of the city.

The laws of the twelve tables have been justly charged with inexcusable severity. They are written, says Mr. Gibbon, like the statutes of Draco, in characters of blood. They approve the inhuman and unequal principle of retaliation; and the forfeit of an eye for an eye, a tooth for a tooth, a limb for a limb, is rigorously exacted, unless the offender can redeem his freedom by a fine of 300 lbs. of copper. Besides the slighter chastisements of flagellation and servitude very liberally distributed by the decemvirs, nine crimes of a very different complexion are adjudged worthy of death: *viz.* 1. Any act of treason against the state, or of correspondence with the public enemy; 2. Nocturnal meetings in the city, under any pretence of pleasure, or religion, or the public good; 3. The murder of a citizen; 4. The malice of an incendiary; 5. Judicial perjury; 6. The corruption of a judge, who accepted bribes to pronounce an iniquitous sentence; 7. Libels or satires; 8. The nocturnal mischief of damaging or destroying a neighbour's corn; 9. Magical incantations. The cruelty of the twelve tables against insolvent debtors merits peculiar notice. After the judicial proof or confession of the debt, 30 days of grace were allowed before a Roman was delivered into the power of his fellow-citizen. In this private prison, 12 ounces of rice were his daily food: he might be bound with a chain of 15 pounds' weight; and his misery was thrice exposed in the market-place, to solicit the compassion of his friends and countrymen. At the expiration of 60 days, the debt was discharged by the loss of liberty or life: the insolvent debtor was either put to death, or sold in foreign slavery beyond the Tyber; but if several creditors were alike obstinate and unrelenting, they might legally dismember his body, and satiate their revenge by this horrid partition.

When the manners of Rome were insensibly polished, the criminal code of the decemvirs was abolished by the humanity of accusers, witnesses, and judges; and impunity became the consequence of immoderate rigour. The Porcian and Valerian laws prohibited the magistrates from insisting on a free citizen any capital, or even corporal punishment; and the obsolete statutes of blood were artfully, and perhaps truly, ascribed to the spirit, not of patrician, but of civil, tyranny. Gibbon's Decl. and Fall, &c. vol. viii.

TABLES of the Law, in Scripture History. See DECA-LOGUE.

TABLES, *New, Tabule Novæ*, an edict occasionally published in the Roman commonwealth, for the abolishing all kinds of debts, and annulling all obligations.

It was thus called, in regard that all antecedent acts being destroyed, there were nothing but new ones to take place.

TABLE, among *Jewellers*. A *table diamond*, or other precious stone, is that whose upper surface is quite flat, and only the sides cut in angles: in which sense, a diamond cut *table-wise*, is used in opposition to a rose-diamond. See DIAMOND.

TABLE, in the *Glass-Manufacture*, denotes a circular sheet of finished window-glass. These tables are generally four feet in diameter, and each of them weighs 10, 10½, or 11 pounds. Twelve of these is called a *side* or a *crate* of glass. Some tables of glass have been four, and even five feet in diameter. Such have been made by Messrs. Attwood and Smith, formerly Hammond and Smith, of Gateshead, in the county of Durham; and these tables are the more valuable, as they yield larger squares than ever were made, except in plate-glass, and the quality also is of the best kind. The centre of the table of glass, where the punting iron was attached, is of course somewhat thicker, and is denominated by the workmen "bull's eye:" nevertheless, the rest of the plate is of an uniform thickness.

TABLE is also used for an index, or repertory, put at the beginning or end of a book, to direct the reader to any passage he may have occasion for.

Thus we may say, *table of matters; table of authors quoted; table of chapters, &c.* Tables, of themselves, sometimes make large volumes, as that of Dravitz on the civil and canon laws.

TABLES of the Bible, are called *Concordances*. See CONCORDANCE.

TABLE-RENTS. See BORD-LANDS.

TABLES of Houses, among *Astrologists*, are certain tables, readily drawn up, for the assistance of practitioners in that art, for the erecting or drawing of figures or schemes. See HOUSE.

TABLES, in *Mathematics*, are systems of numbers, calculated to be ready at hand for expediting astronomical, geometrical, and other operations. See CANON.

TABLES, *Astronomical*, are computations of the motions, places, and other phenomena of the planets, both primary and secondary. See each planet.

The oldest astronomical tables are the Ptolemaic, found in Ptolemy's *Almagest*; but these now no longer agree with the heavens.

In 1252, Alphonso XI. king of Castile, undertook the correction of them, chiefly by the assistance of Isaac Hazen, a Jew; and spent four hundred thousand crowns therein. Thus arose the *Alphonsoine* tables, to which that prince himself prefixed a preface. But the deficiency of these, also, was soon perceived by Purbachius and Regiomontanus; upon which Regiomontanus, and after him Waltherus and Warnerus, applied themselves to celestial observations, for the farther amending of them; but death prevented any progress therein.

Copernicus, in his books of the celestial revolutions, instead of the Alphonsoine tables, gives others of his own calculation, from the latter, and partly from his own observations.

From Copernicus's observations and theories, Erasmus Reinholdus afterwards compiled the *Prutenic* tables, which have been printed several times, and in several places.

Tycho de Brahe, even in his youth, became sensible of the deficiency of the *Prutenic* tables; which was what determined him to apply himself, with so much vigour, to celestial observations: yet all he did, by them, was to adjust the motions of the sun and moon; though Longomontanus, from the same, to the theories of the several planets published in his "*Astronomia Danica*," added tables of their motions, now called the *Danish* tables; and Kepler likewise, from

from the same, in 1627, published the *Rudolphine* tables, which are much esteemed.

These were afterwards, anno 1650, turned into another form, by Maria Cunitia, whose astronomical tables, comprehending the effect of Kepler's physical hypothesis, are exceedingly easy, and satisfy all the phenomena, without any trouble of calculation, or any mention of logarithms; so that the Rudolphine calculus is here greatly improved.

Mercator made a like attempt in his *Astronomical Institution*, published in 1676, and the like did J. Bap. Morini, whose abridgement of the Rudolphine tables was prefixed to a Latin version of Street's "*Aitronomia Carolina*," published in 1705.

Lansbergius, indeed, endeavoured to discredit the Rudolphine tables, and framed *Perpetual* tables, as he calls them, of the heavenly motions; but his attempt was never much regarded by the astronomers; and our countryman Horrox warmly attacked him, in his defence of the Keplerian astronomy.

Since the Rudolphine tables, many others have been published; as the *Philolaic* tables of Bullialdus; the *Britannic* tables of Vincent Wing, calculated on Bullialdus's hypothesis; the *Britannic* tables of Newton; the French ones of the count de Pagan; the *Caroline* tables of Street, all calculated on Dr. Ward's hypothesis, and the *Novalmajeftic* tables of Riccioli. Among these, however, the *Philolaic* and *Caroline* tables are esteemed the best; inasmuch that Mr. Whiston, by the advice of Mr. Flamsteed (a person of undoubted authority in such cases) thought fit to subjoin the *Caroline* tables to his astronomical lectures.

The *Ludovician* tables, published in 1702, by M. de la Hire, are constructed wholly from his own observations, and without the assistance of any hypothesis; which, before the invention of the micrometer, telescope, and the pendulum clock, was held impossible.

Another set of tables, Dr. Halley, the astronomer royal, long laboured to perfect.

M. le Monnier, in 1746, published in his "*Institutions Astronomiques*" tables of the motions of the sun, moon, and satellites, of refractions, and of the places of the fixed stars. M. de la Hire has also published tables of the planets, and M. de la Caille tables of the sun. Mayer constructed tables of the moon; and we have many astronomical tables of various kinds, and computed with different views, in our modern books of astronomy, navigation, &c. For an account of several, and especially of those published annually under the direction of the commissioners of longitude, see *ALMANAC*, *EPHEMERIDES*, and *LONGITUDE*.

For *TABLES relating to annuities*, &c. see *ANNUITIES*, *EXPECTATION of Life*, *LIFE-Annuities*, *MORTALITY*, and *RENTS*.

TABLES, Sexagenary. See *SEXAGENARY*.

For *TABLES of the Stars*, see *CATALOGUE* and *STAR*.

TABLES of Sines, Tangents, and Secants, of every degree and minute of a quadrant, used in trigonometrical operations, are usually called *Canons*; which see. See also *SINE*.

TABLES of Logarithms, Rhumbs, used in geometry, navigation, &c. See *LOGARITHM* and *RHUMB*.

TABLES, Loxodromic, are tables in which the difference of longitude, and quantity of the way in any rhumb, are exhibited to every ten minutes of every degree of the quadrant variation of the latitude. See *RHUMB*.

TABLE of Heights, in English feet, from the level of the sea.

The Caspian sea, lower by	-	-	-	306
The Thames at Hampton, Roy	-	-	-	14½
The Tiber at Rome	-	-	-	33

The Seine at Paris, mean height	-	-	-	36;
The Thames, at Buckingham-stairs, 15½ feet below the pavement in the left-hand arcade	-	-	-	43

By barometrical comparison with the Seine and the Mediterranean; but this height is probably too great. Roy supposes the low water of the spring tides at Isleworth to be only one foot above the mean surface of the ocean. He allows seven feet for the difference of the low water at the Nore and at Isleworth, and taking 18 feet for the height of the spring tide, adds one-third of this for the mean height of the sea. At Hampton, the Thames is 13½ feet above low water-mark at Isleworth.

The pagoda in Kew gardens, from the ground	-	-	-	116½
The west end of the Tarpeian rock	-	-	-	151
The Palatine hill	-	-	-	166
The Claudian aqueduct, bottom of the canal	-	-	-	208
The Janiculum	-	-	-	293
The crosses at St. Paul's, from the ground	-	-	-	340
St. Peter's, summit of the crosses	-	-	-	535
From the ground	471	-	-	
Arthur's seat, from Leith pier-head	-	-	-	803
Lake of Geneva	-	-	-	1230
Its greatest depth	393	-	-	
Mount Vefuvius, base of the cone	-	-	-	2021
Skiddaw	-	-	-	3270
Chamouny, ground floor of the inn	-	-	-	3367
Mount Vefuvius, mouth of the crater	-	-	-	3938

For the heights of other mountains, &c.; see *MOUNTAIN*.

It may be observed, with respect to general Roy's calculation of the mean height of the sea, that it does not appear that in rivers, or even in narrow seas, we ought to add one-third of the height of the tides only to that of low water, in order to find the level; for it is probable that even the original tides may often resemble those of lakes, where, for want of breadths, the effects of a spheroidal tide cannot take place, and the elevation and depression are very nearly equal.

TABLE, in Heraldry. Coats, or escutcheons, containing nothing but the mere colour of the field, and not charged with any bearing, figure, or moveable, are called *tables d'attente*, *tables of expectation*, or *tabula rasa*.

TABLE Bay, in Geography, a bay situated on the west coast of the southern extremity of Africa, near which are the fort and town of the Cape of Good Hope. This bay is formed by three lofty mountains. Cape Town, the capital of the colony, lies on the S.E. angle of the bay. The primary object to which Table bay is subservient, is the convenience of a plentiful stream of pure limpid water, rushing out of the mountain, and this circumstance determined the first settlers in their choice of the site for the town. If this had not been the case, the first settlers would unquestionably have given the preference to Saldanha bay, the only defect of which is the want of fresh water near it; whereas Table bay is faulty in every point that constitutes a proper place for the resort of shipping, and so boisterous for four months in the year, as totally to exclude all ships from entering into it. The anchoring ground in this bay is tolerably good; but the shifting of the sand leaves bare sometimes whole ridges of the same kind of hard blue schistus that appears every where on the west shore of the bay. These ridges are so sharp, that a cable that comes across them will be cut in pieces. Hence it has happened, that the bay is full of anchors, which have never been fished up, and these contribute, as well as the rocks, to cut and chafe the

the cables of ships. If some pains be not taken to remove the anchors, the number of which is annually increasing, a clear anchorage for a single large ship will not be found. It has been proposed to sink mooring-chains for large ships, instead of their lying at anchor. During the S.E. winds, which blow from September to the end of April, and which is the season when all ships bound for the Cape resort to Table bay, the only danger is that of their being driven out to sea from the wear and tear of the cables. However, as the sea is not high, it is hardly possible for a ship to go on shore, unless it be on the S. point of Robben island, which being distant seven or eight miles, may be always avoided. Within this island and the continent there is excellent anchorage, where ships so driven out usually bring up. Here also ships intending to come into Table bay generally wait the abatement of a S.E. wind, if it shall happen to blow too strong for their working up against it. This island is too small and too far to afford the least shelter to Table bay from the N.W. winds that blow in the winter months. Naval officers seem to be divided in opinion as to the preference of Table bay or Simon's bay, (see *SIMON'S BAY*), which lies on the eastern side of the peninsula, in the great bay of False, and which is the usual resort of shipping for five months in the year. Both are defective, but the latter appears to be more secure, from the circumstance of few, if any, ships having been ever known to drive on shore from their anchors, whilst scarcely a season passes without the loss of some in Table bay. In the winter months, when the wind blows from N. to N.W., 40 or 50 ships may lie at anchor perfectly secure in Simon's bay, and eight or ten may be sufficiently sheltered in the strongest south-eastern. From a survey of the Great False bay in 1797, the exact situation was ascertained of a very dangerous rock, placed directly in the passage of ships into Simon's bay. The months in which ships usually resort to this bay, are from May to September inclusive. The distance from Cape Town, being 24 miles, and the badness of the road, mostly deep sand and splashes of water, render the communication at all times difficult, but more especially in winter; and few supplies are to be had at Simon's town, a name given to a collection of about a dozen houses. We have a chart of this bay in the second volume of Barrow's *Africa*. S. lat. $53^{\circ} 50'$. E. long. $18^{\circ} 15'$.—Also, a bay on the E. coast of Labrador. N. lat. $53^{\circ} 44'$. W. long. $20^{\circ} 57'$.

TABLE Island, a small island near the coast of Spitzbergen. N. lat. $80^{\circ} 57'$. E. long. $20^{\circ} 30'$.—Also, one of the New Hebrides, in the South Pacific ocean. S. lat. $15^{\circ} 38'$. E. long. $167^{\circ} 7'$.—Also, a small island in the East Indian sea, near the island of Paraguay. N. lat. $9^{\circ} 15'$. E. long. $118^{\circ} 2'$.—Also, a small island in the East Indian sea. N. lat. $14^{\circ} 8'$. E. long. $93^{\circ} 32'$.

TABLE Mountain, a mountain of Ireland, in the county of Wicklow; 15 miles W. of Wicklow.—Also, a mountain of Africa, near the Cape of Good Hope, so called from its flat summit. In fine weather this mountain is visible at sea at the distance of 28 or 30 miles. Table mountain supplies Table bay and Hout bay with streams of water.

TABLE Mountains, mountains of North Carolina. N. lat. 36° . W. long. $81^{\circ} 40'$.

TABLE Point, a cape on the S. coast of the island of Bali. S. lat. $8^{\circ} 45'$. E. long. $115^{\circ} 11'$.

TABLE River, a river of Louisiana, which runs into the Mississippi, N. lat. $37^{\circ} 12'$. W. long. $90^{\circ} 11'$.

TABLE-Wheel, in *Rope-Making*. To lay ropes, &c. from 2 six-thread line to a two-inch and half rope, a table-wheel is fixed in the wheel-house, at the upper end of the rope-walk,

in a frame fixed in the ground, with two sliding cheeks. The bands which work the whirls, go separately over each whirl, and round the turning-wheel. Some have six sets of whirls of different sizes, with iron spindles, and nibbed or fore-lock hooks at the outer end. A tackle-board, twelve inches broad, and three inches thick, with six holes for the hooks to go through, is fixed above the cheeks upon cleats.

TABLEAU, Fr. This word is used frequently in music, says Rousseau, to express the whole design of a composition in the score: as "this score is quite a picture;" "this opera is full of admirable paintings and imitations of nature."

TABLET, in *Pharmacy*. See *TABELLA*.

TABLIER, LE, in *Geography*, a town of France, in the department of the Vendée; 6 miles S.S.E. of La Roche sur Yon.

TABLING of Fines, is the making a table for every county, where his majesty's writs run; containing the contents of every fine passed each term.

It is to be done by the chirographer of fines of the common pleas; who, every day of the next term, after engrossing any such fine, fixes one of the said tables in some open place of the said court, during its sitting; and likewise delivers to the sheriff of each county a content of the said tables made for that respective county, the term before the affizes, to be affixed in some place in the open court, while the justices sit.

TABLING, in *Ship-Building*, letting one piece of timber into another by alternate scores or projections from the middle, so that it cannot be drawn asunder either lengthwise or sidewise; such are beams, &c.

TABLING, in *Sail-Making*, a broad hem made on the skirts of sails, by turning the edge of the canvas over and sewing it down. It is to strengthen the sail for sewing on the bolt-rope.

TABO DAGROU, or *Little Dieppe*, in *Geography*, a town of Africa, on the Grain Coast.

TABO DUNE, a sea-port of Africa, on the Ivory Coast; 90 miles from Cape Palmas.

TABOA, a town of Portugal, in the province of Beira, on the Mondego; 9 miles S. of Viseu.

TABOCANA, a town of Africa, in the kingdom of Quoja. N. lat. $5^{\circ} 55'$.

TABOCURU, a river of Brasil, which runs into the Atlantic, near the island of Maranhao. S. lat. $2^{\circ} 40'$. W. long. $45^{\circ} 30'$.

TABOGA. See *TABAGO*.

TABOLATO, a town of Mexico, in the province of Culiacan; 30 miles W. of Culiacan.

TABON, in *Natural History*, a name given by the people of the Philippine islands to a bird called in other places *daie*, and remarkable for the largeness of its eggs; though some accounts of these are certainly fabulous.

TABONES, in *Geography*, one of the small Philippine islands, near Mabate. N. lat. $12^{\circ} 12'$. E. long. $123^{\circ} 5'$.

TABOO, a town of Africa, and capital of a country, situated to the E. of Sahara. N. lat. 24° . E. long. $12^{\circ} 10'$.

TABOO, a term used in the Sandwich islands to denote a kind of religious interdiction, of very powerful and extensive operation. With places and persons that were tabooed, all intercourse was prohibited. The word was also used to express any thing sacred, or eminent, or devoted. Cook's Third Voyage, vol. iii. p. 164.

TABOR, or *Hradiste Hory Tabor*, *i. e.* the camp of Mount Tabor, in *Geography*, a town of Bohemia, in the circle of Bechin, founded by the Hussites, situated on a mountain, near the river Luznice, is naturally strong, and

it is fortified in the ancient manner, with a ditch, walls, and bulwarks. It had been the camp of John Ziska in the year 1420, and was raised to a royal borough by the emperor Sigismund. It was taken by stratagem by Rodolph II. in 1611, and also in 1621, 1648, and 1744; 10 miles N.E. of Bechin. N. lat. 49° 27'. E. long. 14° 28'.

TABOR, *Mount*, a mountain of Palestine, frequently mentioned in the Old Testament. (See Josh. xiv. 22. Judg. iv. 6. 12. Pf. lxxxix. 12. Jer. xlvi. 18. Hof. v. 1.) It stands about the middle of Lower Galilee, between Nazareth and the country of Genesareth. According to Josephus, it is 30 furlongs in height, and 26 in compass. It is an insulated mountain, situated on a plain (that of Esdraclon), and having a level area at the summit, very fertile and pleasant. According to Maundrell, this area is of an oval figure, extending in breadth about a furlong, and two furlongs in length. Josephus says, that he caused it to be surrounded by walls, within the space of 40 days, that he might thus, without doubt, render it more inaccessible to the Romans.

An ancient tradition informs us, that Jesus was transfigured upon mount Tabor (see Matt. xvii. 2. Mark, ix. 2. Luke, ix. 28.), and that this is the place which is called by St. Peter the "holy mount." (2 Pet. i. 18.) Some learned authors, however, are of opinion, that the transfiguration happened upon a mountain near Casarea Philippi, *i. e.* upon mount Panium, which is very high, according to Josephus. We find the city called Tabor, mentioned 1 Chron. vi. 77; but it is not well known, how it was situated with relation to the mount.

TABOR, *Tabour, Tabret, or Tabourin*, a small drum; (which see.) It is an accompaniment to a small pipe or fife; instruments very animating in a country dance.

TABORITES, or THABORITES, in *Ecclesiastical History*, a branch or sect of the ancient Hussites.

The Hussites, towards the beginning of the 15th century, dividing into several parties, and about the year 1420, into two great factions; one of them retired to a little mountain or rock, situate in Bohemia, 15 leagues from Prague, and there put themselves under the conduct of Ziska; building themselves a fort or castle, and a regular city, which they called *Tabor* or *Thabor*, either from the general word *thabor*, which in the Slavonic language signifies *castle*; or from the mountain *Tabor*, mentioned in Scripture; and hence they became denominated *Thaborites*. Those of the other party were denominated *Calixtins*.

The Taborites not only insisted upon reducing the religion of Jesus to its primitive simplicity, but required also that the system of ecclesiastical government should be reformed in the same manner, the authority of the pope destroyed, and the form of divine worship changed: they demanded the erection of a new church and hierarchy, in which Christ alone should reign, and all things should be carried on by a divine direction and impulse. In maintaining these demands, some of their leaders went so far as to flatter themselves with the chimerical notion, that Christ would descend in person upon earth, armed with fire and sword, to extirpate heresy, and purify the church from its numerous corruptions. This enthusiastic class of Hussites alone, Mosheim says, we are to look upon as accountable for all those acts of violence, which are too indiscriminately laid to the charge of the Hussites in general, and to their two leaders, Ziska and Procopius, in particular. After the time of the council of Basil, in 1433, which endeavoured, though without success, to reconcile the Taborites with the Roman pontiff, they began to review their religious tenets, and their ecclesiastical discipline, with a design to

render them more perfect. This review, conducted with great prudence and impartiality, gave a rational aspect to the religion of this sect, who withdrew themselves from the war with Sigismund, in which they were engaged, abandoned the doctrines, which, upon serious examination, they found to be inconsistent with the genius and spirit of the Gospel, and banished from their communion all those whose disordered brains or licentious manners might expose them to reproach. The Taborites, thus new-modelled, were the same with those Bohemian brethren (or Picards, *i. e.* Beghards, as their adversaries called them) who joined Luther and his successors at the Reformation, and of whom there are at this day many of the descendants and followers in Poland and other countries. Molh. Eccl. Hist. vol. iii.

TABORNOST, in *Geography*, a town of Africa, in the country of Darah; 120 miles S.E. of Morocco.

TABORO, a mountain of Naples, in Principato Citra, on the confines of Lavora.

TABOROWKA, a town of Poland, in the palatinate of Kiev; 16 miles W.N.W. of Bialacerkiev.

TABOTUVO, a town of Africa, on the Ivory Coast; 45 miles S.W. of Druin.

TABOU, a town of Africa, on the Ivory Coast; 36 miles S.W. of Druin.

TABOURET, *Privilege of the*, in France, is a privilege some great ladies enjoy, to sit, or have a stool, in the queen's presence.

TABRE, in *Geography*, a town of Hindoostan, in the Carnatic; 15 miles E. of Volconda.

TABREEZ, or TAURIS, a city of Persia, the capital of the province of Adirbeitzan, or Azerbaijan. Sir William Jones, and other learned persons, are of opinion, that this city was the ancient Ecbatana. M. D'Anville, adjudging that honour to Hamadan, conceives Tauris to be Gaza, or Gunzaca, where Cyrus deposited the treasures of Cræsus, and which was afterwards taken by Heraclius. According to the Persians, Zobeida, the celebrated wife of Haroun-ul-Rashid, was its founder; but on their authority we can place little reliance. It is certain, however, that Tauris was a favourite residence of Haroun-ul-Rashid; and though he had not the honour of founding this city, it is probable that he improved and embellished it in a considerable degree. In the days of Chardin, it was one of the largest and most populous cities in the East, and, according to that traveller, contained half a million of inhabitants. But no town has suffered more from the ravages of war. Situated towards the frontiers of contending empires, it has alternately been occupied by Turks, Tartars, and Persians, and has been captured and sacked eight different times; but its ruin has been chiefly owing to the number of earthquakes which have, at different times, levelled its proudest edifices with the dust.

Tabreez does not now contain more than 30,000 inhabitants, and is one of the most wretched cities in Persia. It is seated on an immense plain at the foot of a mountain, on the banks of a small river, the waters of which are consumed in the cultivation. This river, called Agi, proceeds from the mountains at Bustum, and enters the plain of Tabreez three miles N. of that city. This city is surrounded with a decayed wall, and the only decent house in the place is a new barrack, erected by the prince for the accommodation of his troops. The ruins of the ancient city are very extensive and very mean, being nothing but a confused mass of old mud walls. Tabreez is situated in N. lat. 38° 10'. E. long. 46° 37'. Kinneir's Mem. of the Persian Empire.

TABUDA, in *Ancient Geography*, a river of Belgic Gaul, in the country of the Morini, near Gessoriacum Navale. Ptol.

TABUE',

TABUE', in *Geography*, a town of Egypt, on the Nile; 9 miles S.W. of Menuf.

TABUIL, a town of South America, in the province of Tucuman; 20 miles E. of St. Fernando.

TABULAR SPAR, in *Mineralogy*, *Spathon tables*, Häüy; a species of lime-stone, generally of a greyish-white colour, but sometimes inclining to greenish-yellow or reddish-white. It occurs massive and crystallized in rectangular four-sided tables. The lustre of the principal fracture is shining and pearly; the structure is imperfectly lamellar. Tabular spar occurs in large distinct prismatic concretions, which are promiscuously aggregated: it is translucent, and phosphoresces when scratched with a knife: its specific gravity is 2.86. It is sometimes friable. When put into nitrous acid it effervesces, and then falls into grains. It is infusible by the blowpipe. The analysis, as given by Klaproth, is

Silex	-	-	-	50
Lime	-	-	-	45
Water	-	-	-	5

This mineral is of rare occurrence; its locality, as given by Stütz, is at Dognaska, in the bannat of Temesvar, in Hungary, where it occurs in blue-coloured primitive lime-stone, with garnets, actinolite, tremolite, and variegated copper. It is said by Estner to occur at Ozavitza. In the new system of mineralogy proposed by Berzelius, this mineral is denominated a *bifiliciate of lime*; the oxygen contained by the different constituent parts being in the proportion of 6.3 and 1; the silex containing twice the oxygen of the lime, and the water the sixth part.

TABULARIUM, among the Romans, the name of that part of the treasury where the Elephantine books were kept.

TABULARIUS. See **TABELLIO**.

TABULARUM APERTURA. See **APERTURA**.

TABULATUM. See **TABELLA**.

TABUM, a word used by medical writers, to express a thin, sanious, and putrid humour, flowing from old ulcers, or from mortified parts, in cases where the vital powers are not sufficient for the generation of a perfect or concocted matter.

TABY, in *Geography*, a town of Sweden, in East Gothland; 14 miles S.E. of Nordkiöping.

TACA, a town of Japan, in the island of Xicoco; 20 miles S.W. of Tosa.

TACALALPO, a town of Mexico, in the province of Tabasco; 23 miles S.W. of Tabasco.

TACALAYO, a town of South America, in the province of Chaco; 35 miles N. of St. Salvador de Jugui.

TACALEA, a town of South America, in the province of Carthagen, at the conflux of the Cauca and Madalena; 85 miles S.E. of Carthagen.

TACAMAHACA, in *Gardening*, a tree of the ornamental and sweet-smelling kind, which is often planted out in shrubberies, borders, and other parts of pleasure-grounds with much propriety and advantage in its appearance, and the grateful odour which it diffuses all around it. See **POPULUS**.

TACAMAHACA, or *Tacamacha*, a kind of resinous gum, distilling from the trunk of a very large tree, a species of poplar, growing in New Spain, Canada, and other parts of America; but in the greatest abundance, as it is said, in the island of Madagafcar.

The tree is not unlike our poplar-tree, only bigger and taller; its leaves long and green, its fruit red, of the size of our walnuts, exceedingly resinous, and containing a stone like our peaches. See **POPULUS Balsamifera**.

The wood of the tree makes good timber for ships, and the gum it yields serves there for their caulking, though its chief use with us is in medicine.

Two sorts of this resin are sometimes to be met with. The best, called tacamahaca in shells, from its being collected in a kind of gourd shells, is somewhat unctuous and soft, of a pale yellowish or greenish colour, a bitterish aromatic taste, and a fragrant delightful smell, approaching to that of lavender and ambergris. This sort is very rare. That commonly found in the shops is in transparent grains or globes, of a whitish, yellowish, brownish, or greenish colour, and of a less grateful smell than the foregoing.

The first is said to exude from the fruit of the tree; the other from incisions made in the trunk. The tree, as raised among us, affords in its young buds, or the rudiments of the leaves, a resinous juice of the same kind of fragrance.

Tacamahaca is chiefly used as an ingredient in warm nerve plasters; though the fragrance and taste of the finer sort indicate its being applicable to other purposes, as an internal balsamic corroborant. Both kinds dissolve in rectified spirit into a gold-coloured liquor, with a small quantity of remaining impurity: they also impregnate water considerably with their smell and taste, but give out very little of their substance to this menstruum. Lewis. The Indians are said to use it for all kinds of pains. Schroder affirms, that he has seen intolerable pains in the leg removed by it.

TACAMES, or **ATACAMES**, in *Geography*, a government of South America, in the province of Quito, situated W. of the western Cordilleras of the Andes, bordering northward on the department of Barbacoas, in the government of Popayan, westward on the South sea, and southward on the territory of Guayaquil, and reaching along the coast from the island of Tumaco and the house of Hufmal, which lie in N. lat. 1° 30', to the bay of Caracas, and the mountains of Balsamo, in S. lat. 0° 34'. This jurisdiction was long neglected after the conquest of it by Sebastian de Belalcazar, the introduction of the Christian religion, and its homage to the king of Spain. At length, however, it was discovered that by making settlements here, the intercourse and commerce between Quito and Terra Firma would be facilitated; and with this view, Paul Durango Delgadillo was, in the year 1621, appointed governor of Atacames and Rio de las Esmeraldas. He was succeeded by Francisco Perez Menacho in 1626, and other governors, who failed in the accomplishment of the object for which they were appointed: at length Don Pedro Vicente Maldonado, in 1741, laid open a direct communication betwixt Quito and the Rio de las Esmeraldas, and in recompence of his success he was confirmed as governor in 1746, and in the following year the country was formally constituted a government. This government contains twenty towns, which are but small and poor, five of them situated on the sea-coast, and the others being inland places. The inhabitants of the five towns are Spaniards, Mestizos, Negroes, and Casts, which sprung from these three classes. Those of the other fifteen are in general Indians, among whom are few Spaniards, Mulattos, or Negroes. The spiritual concerns of the district are entrusted to eleven priests, who reside in the great towns, and occasionally visit the others, in which are chapels of ease.

The temperature of Atacames is like that of Guayaquil, and accordingly it produces the same kinds of vegetables, grains, and fruits; some of them to greater perfection, on account of its more elevated situation. It likewise produces in great abundance vanillas, achote, sarsaparilla, and indigo. Considerable quantities of wax are made here, and the forests of the country afford a great variety of trees of

large size and lofty height, fit for domestic and naval purposes. (Linnæus and Ulmer's Voyage, vol. i.) M. d'Anville, in his map of Quito, has marked the supposed lost mine of Emeralds, about 20 miles to the south of the town of Tacames, which is situated in a bay of the Pacific ocean, to which it gives name; 110 miles N.W. of Quito. N. lat. $0^{\circ} 52'$. W. long. 62° .

TACAPHORIS, in *Ancient Geography*, a town of Africa, in the interior of Marmarica. Ptol.

TACARIGUA, *Bay or Lake*, in *Geography*, is situated in the government of Caraccas, in America, about one and a half league from the mouth of the river Tuy. Its form is circular, and its measure is about seven leagues from the sea, on the N.E. to its deepest reefs on the S.E. It abounds in all kinds of sea-fish, and is remarkable for the great number of alligators which are seen in it.

TACASARTA, in *Ancient Geography*, a town of Egypt, upon the route from Memphis to Pelusium. Anton. Itin.

TACASUKI, in *Geography*, a town of Japan, in the island of Nippon; 12 miles N.W. of Meaco.

TACATO, a town of Japan, in the island of Nippon; 48 miles S.S.W. of Jedo.

TACATUA, TACKUS, in *Ancient Geography*, a town situated on the coast of Africa, between Ruficades and Hippone; E. of the promontory of Tapfos, and W. of that of Hippi.

TACAU, in *Geography*, a town of Japan, in the island of Nippon; 90 miles N.W. of Jedo.

TACAXI, a small island of Japan, on the S. coast of the island of Ximo, at the entrance into the gulf of Ximabara.

TACAZZE, a river of Africa, next to the Nile the largest in Upper Abyssinia. Its principal branch rises in Angot, in a plain champaign country, about 200 miles S.E. of Gondar, near a spot called Souami Midre. It has three spring-heads, or sources, like the Nile: near it is the small village Gourri, signifying cold. The other branch of the Tacazzé rises in the frontiers of Begemder, near Dabuco, whence, running between Gouliou, Laita, and Belesfen, it joins with the Angot branch, and becomes the boundary between Tigré and Amhara. This river was called the Siris, or the river of the dog-star, whilst the uncivilized people, the Cushites of the island of Meroë, resided upon its banks. It was then called the Tannush Abay, or the lesser of two rivers that swelled with the tropical rains, which was the name given to it by the peasants from a comparison of it with the Nile. It was the Tacazzé in Derkin, or the dwelling of the Taka, before it joined the Nile in Baja, and it was the Astaboras of those of the ancients that took the Nile for the Siris. It is now the Atbara, giving its name to that peninsula, which it incloses on the E. as the Nile does on the W. and which was formerly the island of Meroë. Tacazzé is a pleasant river, shaded with fine lofty trees, and having its banks covered with tamarisks and bushes singularly fragrant. Its stream is very limpid, its water excellent, and it abounds with a great variety of fish: its coverts are also full of all sorts of game. During the inundation, it carries in its bed nearly one-third of all the water that falls in Abyssinia, rising to about three fathoms, tearing up rocks and large trees in its course, and forcing down their broken fragments scattered in its stream, with a noise like thunder echoed from a hundred hills. This river, though in many respects beautiful, has its disadvantages. From the falling of the first rains in March till November, it is death to sleep in the country adjoining to it, both within and without its banks. The inhabitants retire and live in villages on the top of the neighbouring mountains; and there are all robbers and assassins, who descend from their habitations in the heights to

lie in wait for, and plunder the travellers who pass that way. Its abundance of fish draws together a number of crocodiles: in its adjacent thickets are vast multitudes of lions and hyænas. The ford of this river is situated in N. lat. $13^{\circ} 42' 45''$. Bruce's Travels, vol. iii.

TACCA, in *Botany*, a Malay name, used by Rumphius, and adopted by the classical Forster, as well as by the younger Linnæus. The word being, though barbarous and unmeaning, easy of pronunciation, we are induced to acquiesce in these authorities, and to retain it, along with *Aucuba*, *Pandanus*, and a few other names so circumstanced. Sir Joseph Banks and Dr. Solander had called the same genus, very elegantly and judiciously, *Chaitæa*, from $\chi\alpha\iota\tau\alpha$, a flowing mane, or head of hair, in allusion to the spreading tuft of long capillary filaments, apparently a sort of bractæas, or abortive stalks, accompanying the flowers.—Forst. Gen. t. 35. Linn. Suppl. 37. Schreb. 229. Willd. Sp. Pl. v. 2. 200. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1. 340. Ait. Hort. Kew. v. 2. 306. Juss. 56. Lamarck Illustr. t. 232. Gærtn. t. 14.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Narcissi*, Juss. Akin to *Aroideæ* and *Aristolochiæ*, Brown.

Gen. Ch. Cal. Perianth superior, of one leaf, in six very deep, elliptic-oblong, equal, converging, permanent segments. Cor. none. Stam. Filaments six, opposite to the segments of the calyx, into whose base they are inserted, and half as long, equal, dilated, flat, oblong, incurved and vaulted at the summit; anthers sessile in the hollow of each filament, of two distinct lobes. Pist. Germen inferior, roundish; style short, cylindrical, with three furrows; stigmas three, spreading, dilated, cloven. Peric. Berry ovate, angular, of one cell. Seeds numerous, ovate, striated, "inserted into three receptacles annexed to the coat of the berry." Brown.

Eff. Ch. Calyx in six deep equal segments. Petals none. Filaments vaulted. Stigmas stellated. Berry inferior, angular, with many seeds.

1. *T. pinnatifida*. Pinnatifid Tacca, or Otaheite Salep. Linn. Suppl. 251. Forst. Prodr. 36. Pl. Escl. 59. Willd. n. 1. Ait. n. 1. Loureir. Cochinch. 300. (Tacca; Rumph. Amboin. v. 5. 324—328. t. 112—114. Chaitæa Tacca; Banks Ic. Ined. apud Bibl. Linn. Leontice Leontopetaloides; Linn. Sp. Pl. 448. "Leontopetaloides; Amman. in Comm. Petrop. v. 8. 211. t. 13.")—Leaves pinnatifid.—Native of the East Indies, Cochinchina, the tropical part of New Holland, and the Society Islands; brought to England by Capt. Bligh, in 1793, but has not yet flowered. *Stem*. The root is tuberous and perennial. Leaves one or two, radical, on long stalks, erect, deeply three-cleft, with deeply and variously pinnatifid, acute, entire lobes, a foot long, smooth, reticulated with veins. *Rootstalk* hollow, smooth. *Flower-stalk* radical, about a yard high, hollow, erect, unbranched, terminating in a simple umbel of several drooping, green, somewhat glaucous, flowers, accompanied by an involucre of about as many upright, partly pinnatifid, green leaves, near two inches long; with a greater number of much longer thread-shaped bodies, suspected by Mr. Brown to be abortive flower-stalks. The berries are black, larger than a gooseberry, but little juicy when ripe.

Forster says the fresh root is intensely bitter and acrid, though somewhat milder when cultivated. By being grated, and repeatedly washed in fresh water, it yields a very white mild powder, like starch, which is dried in the sun, and then serves for food, either in the manner of Salep, or baked in the form of cakes, which are even better than those made of Sago. The former mode of using this powder

is customary in the South-sea; the latter in the Molucca, islands. This root is also applied as a plaster, we presume fresh, for deep wounds made with darts or other weapons. It is well known that a similar powder, or mild wholesome flour, is obtained, by washing, from the roots of *Jatropha Manihot*, and various species of *Arum*, even our common *Arum maculatum*, as well as from raw potatoes.

2. *T. integrifolia*. Entire-leaved Tacca. Gawler in Curt. Mag. t. 1488. Ait. Epit. 375.—Leaves ovate, undivided.—Native of the East Indies, from whence it was sent by Dr. Roxburgh to sir Abraham Hume, and flowered in the stove at Wormleybury, in June 1812. The leaves are four or five inches long, probably often more, smooth, quite simple and entire, with one rib and many oblique veins; each on a stout, channelled, brown footstalk. Flowers umbellate, erect or decumbent, of a dingy green, with purple stalks. Leaves of the *involucrum* large, ovate, pale green with many purple ribs, and accompanied by a few white thread-shaped stalks, resembling the former. We have seen no specimen in flower.

TACE, Ital., in *Music*, be silent.

TACET, Lat., is used when a vocal or instrumental part is to be silent during a whole movement: as in a mass, *Christe tacet*; in a concerto or sonata, *Largo tacet*, &c.

TACET, JOSEPH, in *Biography*, an eminent performer and master on the German flute, born, we believe, in France; but who came to England so early, and continued here so long, that by forgetting his own language, he spoke English like a native of the island. He was the first to adopt the additional keys of Quantz to the German flute, in order to correct the bad notes, and increased their number from three to five; though, we believe, he seldom used them all.

TAC-FREE, in *Old Charters*, an exemption from payments.

TACHAN, in *Geography*, a small island in the Chinese sea, near the coast of Cochinchina. N. lat. 12° 35'. E. long. 109° 14'.

TACHAR, a town of Thibet; 23 miles S. of Tourfan.

TACHARD, GUY, in *Biography*, a French Jesuit, who, after accompanying chevalier de Caumont, and the abbé de Choisi, on an embassy to Siam, returned to Europe in 1688, and having made another voyage to the Indies, died at Bengal about 1694. His "Two Voyages to Siam," in 2 vols. Paris, 1686 and 1689, re-printed at Amsterdam in 1700, well received at the time of their publication, have sunk in reputation on account of the credulity and exaggeration of the author, of which satisfactory evidence has been given by chevalier de Forbin, in his *Memoirs*. *Nouv. Dict. Histor.*

TACHAR-SEGHIN, in *Geography*, a town of Thibet; 50 miles S. of Tourfan.

TACHAS, in *Ichthyology*, a name given by some authors to the manati, or sea-cow.

TACHASARA, in *Ancient Geography*, a town of Asia, in the interior of Media, between Zalaca and Pharambara. *Ptol.*

TACHAU, or TACHOW, in *Geography*, a town of Bohemia, in the circle of Pilsen, taken by Ziska by assault, and sacked in the year 1427; 34 miles W. of Pilsen. N. lat. 49° 47'. E. long. 12° 40'.

TACHBACH, a town of Germany, in the county of Henneberg; 8 miles E.S.E. of Meinungen.

TACHEMAL-ONDOUC, a town of Chinese Tartary. N. lat. 45° 59'. E. long. 122° 31'.

TACHEMPSO, or TACHOMIPSO, in *Ancient Geography*, an island of Ethiopia, in the vicinity of Libya, partly occupied by the Egyptians, and partly by the Ethiopians.

TACHENS, in *Geography*, a lake of the archbishopric of Salzburg, five miles long, and about one wide; 14 miles N.W. of Salzburg.

TACHIA, in *Botany*, called *Tachi* by the Galibis in Guiana, because the hollow stem and branches of this shrub serve as a retreat for ants, the above word signifying, in the language of those people, an ant's nest. Aublet Guian. 75. t. 29. See MYRMECIA.

TACHIBOTA. See SALMASIA.

TACHIGALIA, *Tachigali* of the Galibis in Guiana. See CUBÆA.

TA-CHOU-CAO-HOTUN, in *Geography*, a town of Corea; 425 miles E. of Peking. N. lat. 40° 11'. E. long. 124° 53'.

TACHYGRAPHY, called also BRACHYGRAPHY, formed from ταχυς, *swift*, and γραφή, *writing*; the art of quick or short writing.

There have been various kinds of tachygraphy invented: among the Romans, there were certain notes used, each of which signified a word.

The rabbins have a kind of tachygraphy formed by abbreviations, which made a kind of technical words; wherein each consonant stands for a whole word: as רַעֲבֹם, *rafschi*; which stands for *rabbi Schelomoh Jarri*. See NOTARICON.

In France, &c. the only tachygraphy used is, the retrenching of letters, or even whole syllables of words, as in *sdm* for *secundum*, *aut* for *autem*, *d* for *sed*, *o* for *non*, *participaon* for *participation*, &c.

The first printers imitated these abbreviations; but at present they are almost laid aside, except among scribes, &c.

In England we have great variety of methods of tachygraphy, or short-hand; more by far, and those much better, easier, speedier, and more commodious, than what are known in any other part of the world: witness Shelton's, Wallis's, Rich's, Mafon's, Webster's, Weston's, Macaulay's, Annet's, Gurney's, Lyle's, Byrom's, Rees's, and several other short-hands. See STENOGRAPHY.

TACISSO, JEUNG, in *Geography*. See TASSASUDON.

TACIT ACCEPTANCE. See ACCEPTANCE.

TACIT Community. See COMMUNITY.

TACIT Decree, in *Roman Antiquity*, secret deliberations, to which none but old senators were summoned.

J. Capitolinus mentions a decree of this secret kind, which he calls *S. C. tacitum*, and says, that the use of them among the ancients was derived from the necessities of the public, when upon some imminent danger from enemies, the senate was either driven to some low and mean expedients, or to such measures as were proper to be executed before they were published, or such as they had a mind to keep secret even from friends; on which occasions they commonly recurred to a tacit decree, from which they excluded their clerks and servants, performing that part themselves, lest any thing should get abroad. *Capitol. de Gordian. c. 12.*

In the early times of the republic, there are several instances mentioned by historians of such private meetings of the senate, summoned by the consuls to their own houses; to which none but the old or proper senators were admitted, and of which the tribunes usually complained. *Vide Dion-Halic. l. x. 40. l. xi. 55. 57. Middlet. of Rom. Sen. p. 90.*

TACITUS, CAIUS CORNELIUS, in *Biography*, a well-known historian, was born about the year of the Christian era 57, at Interamna, or the modern Terni. His father was a Roman knight, and procurator of Belgic Gaul. Devoted from his youth to the cultivation of literature and rhetoric,

rhetoric, his reputation at maturity was so well established, that he was permitted by Julius Agricola, at the expiration of his consulate, which occurred in the year 77, to form a matrimonial connection with his daughter. Thus introduced into public life, he was honoured by the patronage of Vespasian, Titus, and Domitian. Having discharged the office of prætor, he withdrew from the capital for four years; and on his return he found the latter emperor exercising a tyranny which he bitterly lamented. His prospects, however, were brightened by the accession of Nerva to the consulship, in the year 97; and as his associate Verginius Rufus died before the termination of his office, Tacitus was appointed to be his successor, and commenced his literary career, if the "Dialogue concerning Orators" be not his composition, with an eloquent oration at the funeral of Verginius, of whom Pliny says that he "crowned the felicity of his life by possessing the most eloquent of eulogists at his death." In the early part of Trajan's reign, he concurred with his friend Pliny the Younger, in the accusation of Marcus Priscus for the crimes with which he was chargeable during his proconsulate of Africa. The conduct of Tacitus and Pliny on this occasion was honoured by the encomium of the senate in their sentence and condemnation of the culprit. The future circumstances of his life, and the precise time of his death, are unknown; but as he makes no allusion to the reign of Adrian, it is most probable that he did not survive that of Trajan.

The principal works of Tacitus were his "Annals," and his "History." The former comprehended the Roman affairs from the death of Augustus to that of Nero; but it has been transmitted to us in a very mutilated state. The latter comprised the period from the end of Nero to the death of Domitian; and now exists in an imperfect state, as the narrative does not extend far beyond the accession of Vespasian. His other works are, a "Life of Agricola," and a treatise "On the Manners of the Germans." The style of his writings is singularly concise, abrupt, and elliptical, so that the reader is often at a loss to comprehend his meaning. His aim seems to have been to comprize much in a small compass, and he has thus furnished a great variety of political maxims, which, by the brevity with which they are expressed, are peculiarly adapted to impress the memory. It is observed, however, by one of his biographers, that he occasionally discovers "an affectation of converting common remarks into aphorisms, and of philosophizing when he was only required to narrate." Nevertheless, as the same author remarks, "no prose writer in any language surpasses or perhaps equals him in force of description, and the choice of circumstances by which he dramatizes a scene, and brings it before the eyes of his reader; and no want of perspicuity appears in his style when employed in the relation of striking events." The writer whom we are now citing extols the moral merits of Tacitus as an historian, and gives him his full share of praise for inculcating the noblest principles of action, both public and private, and displaying the evils arising from uncontrolled power, united, as it generally must be, with vice and tyranny. "He was guarded," says the biographer, "by philosophy against credulity, and by the love of truth against calumny." He adds, "upon the whole, whatever defects may be justly imputed to him, his works can never fail to keep a distinguished place among the most valuable treasures which antiquity has bequeathed to us." The following editions of the works of Tacitus are those which are held in the highest estimation: *viz.* Ryckii, Lugd. Bat. 1687, 2 vols. 12mo.; Gronovii, Traj. 1721, 2 vols. 4to.; Ernesti, Lips. 1752 and 1772, 2 vols. 8vo.; Brotier, Paris, 1771, 4 vols. 4to. and 1776, 7 vols. 12mo.

Many translations in different languages are extant. Brotier Præf. Gen. Biog.

TACITUS, M. CLAUDIUS, an emperor of Rome, who was advanced to this eminence from the rank of senator, to which he belonged at the time of Aurelian's death, A.D. 275. He was then about 75 years of age, having been consul twice, bearing the character of distinguished wisdom and moderation, and enjoying a patrimony valued at between two and three millions sterling. An interregnum took place in consequence of the refusal of the army and senate to nominate an emperor, and had lasted nearly eight months. Tacitus wished to refer the choice to the army; but finding that he was the person to whom the attention of the public was directed, he withdrew to his country seat in Campania, and continued there two months. At length, the consul convoked the senate, and Tacitus appeared in the assembly. Being asked his opinion on the subject that had occasioned delay, he arose to reply; but he was immediately saluted, amid general acclamations, with the titles of Augustus and emperor. The plea of his age and infirmities was of no avail; constrained to accept the high honour on Sept. 25, A.D. 275, he entered on his office; the Roman people and the prætorian guards approving and confirming his election. His first object was to restore to the senate rights and privileges, which served to render the constitution a limited monarchy. After thus gratifying the senators, he proceeded to regulate and reform the public morals; exhibiting in his own conduct an example of simplicity and frugality, whilst he was unusually munificent in his attention to public objects. To literature he was a distinguished patron; and he paid particular respect to his ancestor, the historian Tacitus, directing ten copies of his works to be annually deposited in the public libraries. In order to secure the attachment of the army, he visited the camp at Thrace at the commencement of the year 276, promised the usual donative, and inflicted punishment on the principal persons who had been concerned in the murder of Aurelian. In process of time, dissensions broke out amongst the troops, and the malcontents being joined by the murderers of Aurelian, who had made their escape, either by direct violence, or by the vexation which they occasioned to the aged emperor, terminated his life at Tyana, in Cappadocia, after a reign of 200 days. *See* Gibbon.

TACK, in *Sail-Making*, the foremost lower corner of all fore and aft sails.

TACK, a rope used to confine the clues of the main and fore courses forward occasionally in a fixed position, and also to confine the tacks of stay-sails, boom-sails, and fore-sails of sloop; and the outer lower corners of studding-sails. The tacks of the main and fore courses are ropes cable-laid, and made tapering, having a large wall-knot at one end, which prevents its drawing through the clue of the sail.

TACK is also applied by analogy to that part of any sail to which the tack is usually fastened. A ship is said to be on the starboard or larboard tack when she is close-hauled, with the wind upon the starboard and larboard side: and in this sense, the distance which she sails in that position is considered as the length of the tack; although this is more frequently called a *board*. Falconer.

TACK, *To*, in *Sea Language*, is to change the course from one board to another, or to turn about the ship from the starboard to the larboard tack, in a contrary wind.

Tacking is also used, in a more enlarged sense, to signify that manœuvre in navigation, by which a ship makes an oblique progression to the windward, in a zigzag direction. This, however, is more usually called *beating*, or *turning* to windward.

windward. In order to explain the theory of tacking a ship, recourse must be had to the two first laws of motion, recited under *Laws of NATURE*: according to which, it is easy to conceive how a ship is compelled to turn into any direction, by the force of the wind acting upon her sails in horizontal lines. For the sails may be so arranged as to receive the current of air, either directly, or more or less obliquely: hence the motion communicated to the sails must necessarily conspire with that of the wind upon their surfaces. To make the ship tack, or turn round with her head to the windward, it is therefore necessary, after she has received the first impression from the helm, that the head-sails should be so disposed as to diminish the effort of the wind, in the first instant of her motion, and that the whole force of the wind should be exerted on the after-sails, which operating on the ship's stern, carries it round like a weathercock. But since the action of the after-sails to turn the ship will unavoidably cease, when her head points to the windward, it then becomes necessary to use the head-sails to prevent her from falling off, and returning to her former situation. These are, accordingly, laid aback on the lee-side, to push the vessel's fore-part towards the opposite side, till she has fallen into the line of her course thereon, and fixed her sails to conform with that situation.

The first effort to turn the ship in tacking, communicated by the helm, which is then put to the lee-side, being announced by the pilot, or commanding officer, who then calls out, *Helm's a-lee!* the head-sails are immediately made to shiver in the wind, by casting loose their sheets or bowlines. The pilot then calls, *Up tacks and sheets!* which is executed by loosening all the ropes which confine the corners of the lower sails, in order that they may be more readily shifted to the other side. When the ship has turned her head directly to windward, the pilot gives the order to turn about the sails on the main and mizen-masts, by the exclamation, *Haul main-sail, haul!* the bowlines and traces are then instantly cast off on one side, and as expeditiously drawn in on the other side, so as to wheel the yards about their masts: the lower corner of the main-sail is, by means of its tack, pulled down to its station at the chefs-tree; and all the after-sails are, at the same time, adjusted to stand upon the other board. Finally, when the ship has fallen off five or six points, the pilot cries, *Haul off all!* or, *let go, and haul!* the sails on the fore-mast are wheeled about by their braces; and as the ship has then a tendency to fall off, she is checked by the effort of the helm, which for that purpose is put *hard-a-lee*. The fore-tack, or the lower corner of the fore-sail, being fixed in its place, the bowlines are hauled; and the other sails, which have been neglected in the hurry of tacking, are properly arranged to the wind; which exercise is called *trimming the sails*. Falconer.

TACK of a Flag, a line spliced into the eye at the bottom of the tabling, for securing the flag to the haliards.

TACK-Stopper. See STOPPER.

TACK, in *Rural Economy*, a term provincially made use of in some districts, as Gloucestershire, to signify a fort of shelf, within the dairy, for laying cheese upon while they are drying, and afterwards.

TACK, or *Tack of Land*, in *Agriculture*, is a word used in some parts of the nation, as those of the north, for the term of a lease. It, in short, denotes the means by which land is holden by the farmer, from the proprietor or real owner, in the intention of cultivation and improvement, for the advantages of the produce. It was in its origin a sort of feudal or military tenure of land: accordingly it is found, the writer of the corrected *Agricultural Report* of the

County of Peebles says, that, as military tenants, at first, became tenants for life, from being tenants at will; so the first notion of giving the security of independence to the cultivator of the soil, in Scotland, as elsewhere, was to give him security of possession for life. The life-rent tack seems, it is said, the first adopted species or kind of tack-holding, rendering the possessor independent, his situation respectable, and his rights and interests regarded. Superior privileges were accordingly bestowed upon the life-rent tack; the property in this tack was, and is, considered to be so complete, as to imply the full power of its alienation, in defiance of the proprietor's supposed essential and inherent right of the *delectus personæ*; and, when granted to a woman, was not considered as forfeited upon her marriage, as implying assignment contrary to the proprietor's right of *delectus*, in consequence of its falling under the husband's *jus mariti*; although such, it is said, is the absurd construction of Scots law, in regard to the effect of a woman's marriage, upon a tack for definite time, to which she should fall heir by inheritance, or even, perhaps, acquire by personal contract. The period of nineteen years seems, it is said, in Scotland, to have been considered as equivalent to the life of a person of age to enter upon a life-rent tack; and that, from this analogy, various privileges, originally communicated to the life-rent, would seem to have been extended to this species or kind of tack. As nineteen years may, however, be considered as a favourable exchange for a life-rent, this is, it is thought, probably the reason why the Scots tenant seems to have generally preferred this security; inasmuch that the mention of a tack, without specification of the term, in common habit suggested the idea of a nineteen years' lease. The privileges granted to cultivators, by legislating proprietors, seem, it is said, to have been granted slowly, with reluctance, and to no greater extent than what indispensable utility obviously and absolutely required. A short-sighted avarice, it is observed, wished to grasp at the fruits of the cultivation effected by the tenant's stock, as speedily as possible; even so prematurely, as to allow no sufficient security of time for their being effected at all: and the genius of law seems, it is thought, to have been universally inimical, both in modern and in ancient nations, to the long duration of leases, which seemed to keep back the proprietor from reaping the benefit of the increased value of his property. And that, when subsequent views of utility suggested the propriety of tacks of still longer duration, they were ventured upon with timidity, as an extension of a species of tenure, to which the genius of law was unfriendly; which, as yet, she had not recognized to that extent, and which she might be scrupulous in sanctioning. Such tacks, therefore, it is said, sought shelter under the form of the privileged tack of nineteen years, which had acquired an analogical stability, and whose talismanic influence was thought able to protect them: the whole term meant durst not, it is said, be avowedly expressed; but the tack was granted for two nineteens, or three nineteens of years, until the number of years proposed should be completed in nineteens.

The tack, though still somewhat loaded and encumbered by a remnant of the shackles and tyranny of the feudal state, so as to considerably obstruct and impede the credit and enterprise of agricultural pursuits, yet probably, in consequence of the different enactments and decisions since made, empower the holders by it, in the above part of the kingdom, perhaps to enjoy more security, it is thought, than what was ever bestowed upon the actual cultivators of the soil or land, either in ancient or in modern times. See TENANT and TENURE.

TACKLE, in a *Ship*, a machine formed by the communication

communication of a rope with an assemblage of blocks, and known in mechanics by the name of *pulley*.

Tackles are used in a ship to raise, remove, or secure weighty bodies, to support the masts, or to extend the sails and rigging. They are either moveable, as communicating with a runner; or fixed, as being hooked in an immoveable situation; and they are more or less complicated, with blocks and sheaves, in proportion to the efforts which they are intended to produce. That part of the tackle which is fixed to one of the blocks, &c. is called the *standing part*; all the rest are called *running parts*; and that on which the men pull, when employing the tackle, is called the *fall*. The application of the tackle to mechanical purposes is termed *hoisting* or *bowling*. Falconer.

The power of a tackle will be, the friction not considered, as the number of parts of the fall that are applied to sustain the weight. If a tackle consists of a double and a single block, and the weight to be hoisted is hung to the double block, there will be four parts of the fall; and the weight resting upon four ropes, equally stretched, each must bear the same part of the weight. Thus, suppose the weight hung to the double block be four hundred, then one hundred applied to the fall or hauling part will suspend it; and if as much more power be applied as will overcome the friction, it will purchase the weight: but had the weight been hooked to the single block, it would have rested on three ropes only, each of which would bear a third part of the weight; therefore, a third part of the weight being applied to the hoisting part of the fall, would suspend the weight, when hooked to the single block; as much more being applied as will overcome the friction, would purchase the weight.

The blocks that are fixed are only for the convenience of turning the direction of the fall; they add nothing to the power of the purchase, but, on the contrary, destroy so much as is necessary to overcome their friction, and are, therefore, to be avoided as much as possible.

Ropes, if tight laid, will not easily bend round small sheaves, but will take up a considerable part of the power to force them into their proper direction: hence it follows, that blocks with small pins, large sheaves, and slack-laid ropes, are the best materials to obviate friction, and make tackles with more ease.

The *anchor-stock* tackle is composed of a double block and a single block, strapped, with a hook and thimble. *Boom* tackles are composed of double and single blocks, strapped, with tails, and are used in getting the studding-sail-booms in or out. *Bowline* tackle is composed of a long tackle, and a single block, strapped, with a hook and thimble: it is used to bowse up the main-bowline, when the ship is upon a wind. *Burton* tackles are composed of double and single blocks, and are used with pendants, to set up the shrouds, support the topsail-yards, &c. (See BURTON.) A *fish* tackle is composed of a long tackle, and a single block, strapped, with eyes, and is used with a pendant, to fish the anchor, and get it into its place. *Garnet* tackle is composed of a double block and a single block, strapped, with a hook and thimble: it is hooked to the sciotic-stay in merchant-ships, and is used to hoist goods, &c. in or out. (See GARNET.) *Jigger* tackles are composed of double and single blocks, strapped, with tails, and are used for topping the main and fore-yards by the lifts, &c. (See JIGGER.) *Luff* tackles are composed of double and single blocks, strapped, with a hook and thimble, and are used occasionally at any part of the ship. *Outhaul* tackle is composed of two single blocks, strapped, with tails, and is used to bowse out the jib-boom. *Port* tackles are com-

posed of a single block, attached to a span made fast to the outside of the port-lid, and a runner with two single blocks, all of which are made fast to the side of the beam nearest the port, and are used to hoist and lower the port-lids. *Quarter* tackles are composed of double and single blocks, strapped, with eyes, and lashed to the outer quarter of the yard and the lower block, with a hook and thimble: they are used to hoist up water and provisions. *Reef* tackles are composed of two double or two single blocks: one block is spliced into a pendant, and the other is strapped, with an eye; they are used to draw the extremities of the reefs close up to the yard-arms for reefing the sail. (See REEF.) *Relieving* tackles are luff tackles, used at the fore end of the tillar, when the tillar-ropes are damaged. (See RELIEVING Tackle.) *Ridge* tackle is composed of a double block, and a single block, strapped, with an eye, and is used to suspend the awning in the middle. *Rolling* tackles are luff tackles, used to the topsail-yards, to support them under a press of sail, and preserve the parrals. *Rudder* tackles are composed of a long tackle block and a single block, strapped, with hooks and thimbles: they are used to save the rudder, if unshipped by accident, or to steer by, if the tillar is broken. *Runner* tackles are composed of double and single blocks, and a pendant; the lower block is strapped, with a hook and thimble: they are used to set up the shrouds, and to get the mast-heads forward, for staying the masts. *Stay* tackles, main and fore, are composed of double and single blocks, strapped, with hooks and thimbles, except the block spliced into the pendant: they are used for getting the provisions, &c. out of the fore and main hold, and for getting the boats in or out. The pendant formerly travelled on the stay, by iron thimbles; but this has been discontinued in the navy, as they much injured the stay by the friction. *Staysail-stay* tackles are composed of double and single blocks; the lower blocks are strapped, with a hook and thimble: they are used to set up the jib, and other staysail-stays. *Shifting back-stay* tackles are composed of double and single blocks, strapped, with a hook and thimble, and are used to set up the shifting back-stays, where wanted. *Topmast-stay* and *preventaer-stay* tackles are composed of long tackle blocks and single blocks; the lower blocks are strapped, with a hook and thimble: they are used to set the topmast and preventaer stays. *Fore-top-gallant-stay* tackle is composed of a double and single block, and is used to set up the fore-topgallant-stay. *Tack* tackle is composed of a double and single block, strapped, with hooks and thimbles, and is used for bowling down the tack of fore and aft main-sails. The *top* tackle is composed of double or treble blocks: it is attached to the top-rope-pendant, and is used to erect the topmasts, at the heads of the lower masts. *Truss* tackles are composed of two double blocks, strapped, with hooks and thimbles, and are used to secure the lower yards to their masts, being hooked to the truss-pendant. *Winding* tackle is composed of a fourfold and a treble block, or a treble and a double block, strapped, with eyes: it is attached to the winding-tackle-pendant, and is chiefly used to get in and out the guns. (See Plate II. Rigging, fig. 17.) *Yard* tackles are composed of double and single blocks; the double blocks are spliced into the lower ends of the pendants *f*, and the single blocks are strapped, with hooks and thimbles: they are used to hoist the boats in or out.

TACKLE-Fall, that end of the rope of a tackle which is bowled on, or the rope which composes the tackle.

TACKLE, Gunner's, that which serves to hale the ordnance in or out.

TACKLE Pendants. See PENDANT,

TACKLE,

TACKLE, *Tack*, is a small tackle used occasionally to pull down the tack of the principal sails of a ship to their respective stations. There is also a tackle of this kind constantly fixed to the tacks of the main-sail in brigs, sloops, and schooners, for the same purpose. Falconer.

TACKRAMAH, in *Geography*, a town of Africa, on the Gold Coast. N. lat. $4^{\circ} 52'$. W. long. $3^{\circ} 10'$.

TACKSMAN, in *Agriculture*, the tenant or person who holds or takes a tack of land of another. In subletting, the original person of this kind is, it is said, by the writer of the *Peebles Corrected Agricultural Report*, considered as bound to the proprietor, as well as the sub-tenant; whilst, in assignment, the original tenant is free, substituting the other in his place. In conformity to the analogy of the feudal law, therefore, it is said, as well as to the greater security of the proprietor, the Scottish law is considered as more favourable to sublet, than to assignment; because, in sublet, the first tenant does not relinquish his position as a *quasi*-vassal, and the purposes of the metaphorical *deleatus* may be, thus, considered as metaphorically, or analogically fulfilled by this *fidio juris*, or *quasi*: moreover, too, the security of the proprietor, so far from being weakened, is greatly strengthened, in having his right of hypothec unimpaired, and the security of two instead of one. Upon this principle, it was considered, it is said, by the Scottish law oracle, Erskine, that a power of sublet was implied, in all cases where the contrary was not directly expressed; until the decision, in 1791, came to rectify the misconceptions of the people, when it was decided, that, in a tack of nineteen years, it was implied, in law construction, without any formal stipulation in the lease to that effect, that the power of *deleatus* was retained; and that the tack was neither assignable nor sublettable.

But even Erskine allows, it is said, that, upon legal principles, an express stipulation in the tack against assignees, both *legal* and *voluntary*, would prevent the tack from being evicted by the tenant's creditors: otherwise a tack, unassignable by the tenant's voluntary deed, would, according to him, be evictable by adjudication, at the instance of the tenant's creditors: but even in that case, the creditors would be guilty of *lese-majeste* towards the sacred right of the *deleatus*, were they to bring the reversion of the lease to a fair sale to the best bidder: they are debarred, therefore, it is said, from such unhallowed and irreverend measures; they can only enter upon administration, as responsible factors of the tenant's concerns.

TACKUMBREET, in *Geography*, a town of Africa, or, as it may be rather denominated, the ruins of an ancient town called "Siga," or "Sigeum," once the metropolis of Mauritania, situated on the coast of the Mediterranean, at the mouth of the river Tafna; 44 miles S.W. of Oran. N. lat. $35^{\circ} 30'$. W. long. $0^{\circ} 55'$.

TACKYSERAI, a town of Hindoostan, in Oude; 35 miles W. of Lucknow.

TACLAOUR, a town of Thibet. N. lat. $38^{\circ} 5'$. E. long. $80^{\circ} 51'$.

TACOLA IMPERIUM, in *Ancient Geography*, a port on the western coast of India, on this side of the Ganges; and now *Junkseylon*.

TACOMA, in *Geography*, a town of Mexico; 16 miles N. of Mexico.

TACOMAR-TREE, a name by which some authors call the fugar-cane.

TACON MOUNTAIN, in *Geography*, a mountain of America, in Massachusetts, S. of Great Barrington.

TA-CONG-TO-CHE, a town of the island of Formosa. N. lat. $22^{\circ} 22'$. E. long. $120^{\circ} 4'$.

TA-COO, a town of China, in the province of Pe-tche-li, within the mouth of the Pei-ho, or White river, and the first place of any note in the N.E. frontier of the country. The grand embassy to China arrived at this town in August 1795, and found here a considerable number of yachts, or large covered barges and boats of burden, fit for passing over the shallows of the *Pei-bo*, (which see,) and destined to convey the whole of the embassy as far as the river led towards the capital of the empire. Many of these vessels were eighty feet long, and very capacious; and yet they were so constructed of light wood, as not to sink more than eighteen inches into the water, though they were lofty above it. The cabins were high and airy above: there were births for the crew, and beneath the floors were lockers for securing the necessaries. The yacht appropriated to the ambassador had an apartment, consisting of an anti-chamber, a saloon, a bed-chamber and a closet; and its windows were adorned with a great number of glass-panes; whereas the frames of the windows of the other yachts were generally filled with a kind of paper, manufactured chiefly in Corea, having in its composition an unctuous substance, which rendered the paper more durable when exposed to the weather, as it was much less affected by the rain or any kind of moisture, than that which is made in Europe. During the ambassador's stay before Ta-coo, he was visited by the viceroy of the province, who, by order of the emperor, came from Pao-ting-foo, his usual place of residence, at the distance of a hundred miles; and who took up his abode at the principal temple of Ta-coo, consecrated to the god of the sea, to whom invocations were frequently addressed under the appellation of "Toong-hai-vaung," or king of the Eastern sea. Of this idol there were several figures in different brilliant edifices of porcelain, within one inclosure. Sir George Staunton, in his account of this embassy, has given an engraved representation of this Chinese Neptune, bearing in one hand a magnet, whilst he is sitting on the waves, with firmness, ease, and dignity, and thus conscious of his own security; and in the other, a dolphin, denoting his power over the inhabitants of the ocean. His beard flowed in all directions, and his agitated locks seemed to be intended for a personification of the troubled element. At a small distance from the "Hai-chin-miao," or temple of the sea-god, is the hall of audience of Ta-coo, situated in the midst of a spacious court.

TACOTALPA, a town of Mexico, in the province of Guaxaca, on the river Alvarado; 6 miles S.E. of Alvarado.—Also, a town of Mexico, in the province of Tabasco; 30 miles S.W. of Villa Hermosa.

TA-COU, a river of China, which runs into the sea, 7 miles E.N.E. of Kiao.

TACOUR, a town of Hindoostan, in Mysore; 10 miles S. of Bangalore.

TAC-POU-CHAI, a town of Thibet; 250 miles S.E. of Lassa.

TAC-POU-NAI, a town of Thibet; 240 miles S.E. of Lassa.

TAC-POUY COUROU-NAMKIN, a town of Thibet; 145 miles S.E. of Lassa.

TAC-POUY Lafoi, a town of Thibet; 120 miles S.S.E. of Lassa.

TACPOY, a town of Thibet, and capital of a district; 126 miles S.E. of Lassa. N. lat. $27^{\circ} 53'$. E. long. $92^{\circ} 52'$.

TACQUET, ANDREW, in *Biography*, a mathematician, was born at Antwerp in 1611, and having entered into the order of Jesuits in 1629, was a teacher of the languages and mathematics for several years. He died in 1660. Tacquet was the author of several mathematical works, among

which we may enumerate the following: *viz.* "Cylindricorum et Annularium, Libri V. Elementa brevi historica Narratione de Ortu et Progressu Matheseos," &c. printed at Venice in 1737, with Whiston's additions; "Arithmetice Theoria et Praxis;" "Theoremata selecta ex Archimede." After his death, several of his treatises were published under the title of "Andree Tacqueti Antverpiensis Opera Mathematica," containing "Astronomiz Lib. VIII.," "Geometrie Practice, Lib. III.," "Architecturæ Militaris, Lib. I.:" distinguished by their perspicuity. Montucla. Gen. Biog.

TACSAI RAKI, in *Geography*, a lake of Thibet, about 36 miles in circumference. N. lat. 32°. E. long. 88° 34'.

TACSANLU, a town of Asiatic Turkey, in Natolia; 23 miles N.N.W. of Kiutajah.

TACSONIA, in *Botany*, Juss. 398, a name of Peruvian origin, given by that author to such species of Passion-flower, as have a tubular elongation of the base of their calyx. See PASSIFLORA.

TACTICS, *τακτικα*, formed from *ταξις*, order; the art of disposing forces in form of battle, and of performing the military or naval motions and evolutions. The science of tactics is either *military* or *naval*.

TACTICS, *Military*, comprehend great or general tactics, *la grande tactique* of the French writers, which includes every thing that relates to the order, disposition, and formation of armies, their encampment, and every other circumstance pertaining to stores, baggage, &c.; and also particular or subordinate tactics, more immediately comprising their movements and evolutions. With the former every general officer ought to be thoroughly acquainted; whilst the latter should be well understood by inferior officers and soldiers, and cannot be totally disregarded by those of the former description.

The Greeks were very skilful in this part of the military art; having public professors of it, called *tactici*, who taught and instructed their youth therein. We have an account of the progress of this art among them in Thucydides, Xenophon, and Polybius. Ælian also hath a particular book on this subject; and there is a great deal of it in Arrian, in his History of Alex. M. and in Mauritius, and Leo Imperator.

From the Greeks this art was transmitted to the Romans, among whom it arrived at its highest perfection. Vegetius has given us a compilation and abridgment of authors who have written on this subject; and his work contributed in a considerable degree to the establishment of military discipline in Europe; for which we are greatly indebted to Maurice, prince of Orange, Alexander Farnese, duke of Parma, Coligny, Henry IV. Gustavus Adolphus, &c.

Vossius, De Scient. Mathemat. mentions twenty-four ancient authors on the subject of tactics.

It does not appear what was the field-exercise of the infantry in our ancient armies. After the Revolution, our system of discipline was chiefly taken from the Dutch, who, under prince Maurice, were the best regulated troops in Europe. Previously to this, the Spaniards were reckoned to have the best disciplined infantry. The exercise was, at the commencement of the last century, and for many years afterwards, encumbered with a number of useless motions. The manner in which the soldiers were armed, with their heavy muskets, bandoliers, &c. obliged them to make wide motions, and to draw up with very extended ranks and files. For an account of the exercise and evolutions of the infantry and cavalry at this period, we refer to Grose's Military Antiquities, vol. i. Of late, great alterations have taken place in the field-exercise and manœuvres both of the cavalry and the infantry. Most of the dragoon regi-

ments have been made light; and a new sword-exercise has been adopted for the cavalry. The whole system of the army has been rendered uniform, by regulations issued from the adjutant-general's office. Within the last 60 or 70 years, the British infantry has been gradually falling into the Prussian system; and the new regulations are almost wholly founded on the Prussian institution. For the particulars, the reader is referred to the "Rules and Regulations for the Formation, Field-exercise, and Movements of his Majesty's Forces," and the articles *MANUAL EXERCISE* and *BATTALION*.

The subject of this article has been already discussed under the following heads; *viz.* ARMY, BATTALION, BATTLE, *Order of BATTLE*, CAMP, CAMPAIGN, CASTRAMETATION, COLUMN, ENGAGEMENT, EVOLUTION, EXERCISE, LINE, PHALANX, in which order the Gauls and other nations fought in the time of the Romans, and which order still prevails, under some disadvantages, throughout Europe; WAR, &c. &c.; so that we have here little to add.

We shall here observe, that the principal object of the Prussian tactics under Frederick the Great was that of concentrating forces, and attacking the chief points of the enemy, not at one time, but one after another; whereas the tactics which have been uniformly pursued by the French, since the commencement of their revolution, have been founded on the principle of attacking all points with divided forces at the same time; thus extending their force, whilst that of the Prussian was compressed.

TACTICS, *Naval* or *Maritime*, comprehend the orders and signals which are directed to be observed by fleets preparing for action or actually engaged, together with the manœuvres and modes of attack that are then to be practised, and also a knowledge of the rates of ships, their various appendages, and the mode of constructing them. Of this branch of tactics, a copious account will be found under several articles, particularly BATTLE, ENGAGEMENT, EXERCISE, and *LINE of Battle*; under which last article we have referred to Clerk's (not Clarke's) Essay on Naval Tactics, of which a second edition was published in 1804, which those who are desirous of information on the various modes of attack to windward and leeward, and by cutting the line, will consult; but which does not admit of abridgment within the limits that we are under the necessity of prescribing to ourselves.

TACTICS is also used for the art of inventing and making machines for throwing of darts, arrows, stones, fire-balls, &c. by means of slings, bows, and counterpoises. Vegetius, Hiero, &c. have written on these machines; and we have them described and figured by Lipsius.

TACTILE, or TANGIBLE, in the *Schools*, something that may fall under the sense of feeling.

Though atoms be corporeal, yet are they not either tactile or visible, by reason of their smallness.

The principal tangible qualities are, heat, cold, dryness, hardness, and humidity. See HEAT, &c.

TACTION. See FEELING.

TACTION, in *Geometry*. See TANGENT.

TACTUS, the *Touch*, in *Midwifery*, is the exploration of the state of the vagina and uterus, and of the situation of the fœtus, and whatever else is contained in it. Hippocrates, in his Treatise on the Diseases of Women, has been very full and exact in his directions upon this subject.

TACTUS, *Tact*, in *Music*, before the use of bars, implied nearly the same thing as a bar: that is, the time when the hand or foot is beaten down in marking the measure. *Tatto*, Ital., the same.

TACUA, in *Ancient Geography*, a river of Italy, in Liguria, E. of Rutuba.

TACUA, in *Geography*, a town of Peru, in the diocese of Arequipa; 20 miles E. of Arica.

TACUBA, a town of Mexico, N.W. of the city of Mexico.

TACUMADARS, or **TIGUMEDES**, a town of Africa, in the country of Darah, the original country of the reigning sherifs of Morocco.

TACZLI, a river of European Turkey, which runs into the Danube, near Kilia, in Bessarabia.

TADAPOOPLY, a town of Hindoostan, in Mysore; 5 miles S.E. of Sattimungulum.

TADCASTER, a market-town in the West Riding of the county of York, England, is nine miles S.W. from the city of York, and 190 miles N. of London. In the year 1811, it contained 382 houses, and 1483 inhabitants. The name of this place implies a Roman station, and accordingly we find, that the Calcaria of Antoninus was situated on the course of a Roman road, between Eboracum or York, and Mancunium or Manchester, at nine miles distance from the former; and this agrees with the site of the present town. Dodsworth and some other antiquaries, however, place the Calcaria at Newton-Kyme, about a mile and a half W. of Tadcaster. Horsley in "*Britannia Romana*," and Drake in "*Eboracum*," are decisive in fixing the Roman station at Tadcaster. It appears that many Roman coins have been found here: some banks and ditches surround the town, and on the south side of the river are remains of intrenchments, called the Castle. A considerable quantity of stone was taken from this fortress to build a bridge over the river Wharf at the beginning of the 18th century. This bridge is generally described as a very fine structure; and its centre marks the union of the West Riding of the county, with the Ainsty of York and liberty of St. Peter. Tadcaster has a weekly market on Wednesdays, and four annual fairs.

Tadcaster and its vicinity have been twice distinguished and annoyed by the destructive effects of civil warfare: first in the conflicts between the houses of York and Lancaster; and secondly, between the royalists and the republicans, about the middle of the 17th century. On the former occasion, it is related, that between 30,000 and 40,000 Englishmen "fell in deciding the question, whether a tyrant or an ideot should be their master." After Edward IV. had been proclaimed in London, Margaret of Anjou, wife of Henry VI., raised an army, in the north, of about 60,000 men, all attached to the Lancastrian interests. These were assembled at York. When Edward with his army arrived at Pontefract, several skirmishes soon took place on the banks of the Aire, and on Palm-Sunday, 29th March, 1461, the memorable and fatal battle of Towton ensued. On this day it is said, that Henry's army consisted of 60,000 men, and Edward's of about 48,600. These commenced an engagement early in the morning, and fought with great fury during the whole day, with various degrees of success. At length, however, Henry's soldiers fell back, whilst Edward impelled his forward with increased impetuosity. Many of the former were drowned, and several noblemen were slain, whilst Henry and Margaret fled into Scotland. Edward and his soldiers retired to York, and afterwards went to London, where the new monarch was crowned. In the year 1642 another battle occurred at or near Tadcaster. Sir Thomas Fairfax, with about 700 men, occupied this town in behalf of the Parliament, and were attacked by the royal army under the earl of Newcastle. After fighting a whole day,

the former retreated during the night, and left the royalists in possession of the place.

About five miles S.E. of Tadcaster is Scarthingwell-Hall, the seat of lord Hawke, who has paid particular attention to agricultural improvements; and has fitted up a farm with every convenient and useful accommodation. (See *Agricultural Survey of the West Riding of the County of York*.) Three miles south of the town is Haslewood-Hall, the seat of the Vavasours, distinguished for the fineness of its scenery, and the variety and beauty of the prospects from its grounds. Branham Park, the seat of James Lane Fox, esq., is about four miles S.W. from Tadcaster. —Drake's *Eboracum*, fol. 1736. *Beauties of England*, Yorkshire, by J. Bigland, 8vo., 1815. Hargrove's *History*, &c. of Knareborough, 6th edit. 1809.

TADCUL, a town of Hindoostan, in Mysore; 6 miles S.E. of Caveripatam.

TADEMERI, a town of Hindoostan, in Mysore; 100 miles N.E. of Chittledroog. N. lat. 14° 35'. E. long. 78°.

TADEN, a town of the duchy of Holstein; 14 miles E. of Meldorp.

TADEPATRY, a town of Hindoostan, in the circar of Cuddapa; 24 miles N. of Gandicotta.

TADIPOODY, a town of Hindoostan, in Golconda; 20 miles S.E. of Combamet.

TADIVAN, or **TADUAN**, a town of Persia, in the province of Farsistan, situated on a pleasant plain, in the midst of streams, which descend from the neighbouring mountains, and planted with a variety of excellent fruit-trees; 60 miles S. of Schiras.

TADMOR. See **PALMYRA**.

TADORNA, the *Anas tadorna* of Linnæus, in *Ornithology*, a name given by many authors to a species of duck, called by others *vulpanser*, and in English the *shiel-drake*, or *borough-duck*; and by some the *bergander*. See **DUCK**.

It is of a middle size between the duck and goose; its beak is broad, short, and red; and at the origin of the upper chop there is a large red tubercle of flesh; the head and upper part of the neck are of a fine blackish-green, the lower part of the neck white; the breast and upper part of the back surrounded with a broad band of bright orange-bay; the coverts of the wings and middle of the back are white; the nearest scapulars black, the others white; the greatest quill-feathers black; the exterior webs of the next are of a fine green, and those of the three succeeding orange; the coverts of the tail white, and the tail of the same colour, except the two outmost feathers, which are tipped with black; the belly white, divided lengthways by a black line; the legs are of a pale flesh-colour.

They inhabit the sea-coasts, and build in deserted rabbit-holes; but their flesh is not well tasted.

When a person attempts to take their young; they divert his attention by flying along the ground as if wounded, till the brood are secure, and then return and collect them together. Turner, therefore, concludes, that this bird is the chenalopex, or fox-goose of the ancients; and the natives of the Orkneys at this day call it the *fly-goose*.

These birds lay 15 or 16 white roundish eggs. In winter they collect in large flocks. Ray and Pennant.

TADOUN, or **TADIVAN**, in *Geography*, a town of Asiatic Turkey, in Armenia, situated on the west coast of the lake of Van, having a harbour for boats; 120 miles S.S.E. of Erzerum.

TADOUSAC, a town of Lower Canada, at the mouth of the Saguenay, on the left side of the river St. Lawrence.

The native Indians resort hither to exchange furs for cloth, and other European goods. It was first settled by the French, taken by the English in 1629, retaken by the French in 1633, and it was ceded with the rest of Canada; 100 miles N.E. of Quebec. N. lat. 48° 5'. W. long. 69° 40'.

TADPOLE. The animal called by this name is no other than the frog in its first state from the spawn; and this creature furnishes the curious in microscopic observations with a beautiful view of the circulation of the blood, especially when young.

The method of procuring them for this purpose in the greatest perfection, is this: let a small quantity of frog's spawn be kept for some days in water, and from this will be produced a vast number of young tadpoles; these, while very young, are perfectly transparent, and when placed before the double microscope, the heart may be easily seen, and its pulsation regularly observed; and the blood protruded thence may be beautifully seen circulating through the whole body; but particularly in the tail, where, though so very minute, more than fifty vessels may be seen at one view. The young brood grow more and more opaque every hour, and in a day or two the circulation of the blood can only be seen in their tail, or in the fins near the head. Baker's *Microscope*, p. 126.

TÆDA, in *Pharmacy*, a term used by some authors to express certain compositions made up in form of troches. These are sometimes meant as pessaries to be introduced into the vagina, and therefore made into this form; sometimes they are compositions of fragrant or other ingredients for fumigations.

TÆDA, in *Botany*, a name given by some authors to the pinaster, or common wild pine, or mountain-pine.

TÆL. See **TAL.**

TÆNARIA, *τανάρια*, in *Antiquity*, a festival in honour of Neptune, furnished *Tenarius*, from *Tenarus*, a promontory in Laconia, where he had a temple.

TÆNARIA, or *Tenarium*, now *Cape Matapan*, in *Ancient Geography*, a promontory of the Peloponnesus, S. of Laconia, between the gulf of Messenia and that of Laconia. Here were formerly a grotto, and a temple of Neptune, which rendered the place very famous, so that it was reckoned to be one of the mouths of hell, through which Hercules and Psyche descended thither. The temple was accounted an inviolable asylum. On this promontory there were also a statue of Arion, seated on a dolphin, and playing on the lyre, and a fountain of wonderful efficacy.

TÆNARIUM, a town of the Peloponnesus, upon the promontory above described.

TÆNARIUM Marmor, the name of a marble used by the ancient architects and statuaries. There were two kinds of it, very different in colour, but perfectly agreeing in hardness, and in the high polish they are capable of. The first, or most frequent kind, was black, and was dug from the promontory called *Tenarus*, in the Lacedæmonian state; the other, which was more scarce, and much more beautiful, was of a green colour, with a cast of yellow; this was dug in the Tagetan quarries, and was called by some *marmor berlosum*, and *xanthon*.

TÆNIA, or **TENIA**, in *Architecture*, a member of the Doric architrave, resembling a square fillet, or reglet; and serving in lieu of a cymatium.

The word is Greek, *τανία*, which literally denotes a *swathe*, *bandage*, *fillet*, or the like. Barbo renders it by *listel*, but Palladio uses the old name *tania*.

Leon Baptista Alberti calls the *tania*, *regule*, and *fis-*

ciols; and Daviler, *bandelettes*: Philander says, there are two kinds, *viz.* that above-mentioned, which he calls the *lower*; and an *upper*, which serves for a capital to the triglyphs.

TÆNIA, in *Ichthyology*, the name of a fish of the anguilliform, or eel-shaped kind, common in the Mediterranean sea, and brought to market in Italy and elsewhere. This is a species of *cepola* in the Linnæan system. See **CEPOLA**.

TÆNIA Cornuta, the *horned tania*, a name given by many authors to the species of *cobitis*, named by Artedi, the *cobitis* with a forked prickle placed under each eye. This fish is the *cobitis tania* of Linnæus. See **COBITIS**.

TÆNIA, in *Zoology*, a genus of the Intestina order of worms; the characters of which are, that the body is flat and articulated, and that the head is furnished with four sucking bladders. Gmelin, in his edition of the Linnæan system, enumerates eighty-six species, besides several varieties. Their habitations are the viscera of men and of different animals. Our limits will not allow us to specify and describe them. For an account of the *tænia intellinorum* of the human body, or *lumbicus latus*, we refer to **TAPE-WORM**.

TÆNIOLONGA, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana, upon the Iberian sea. Ptol.

TÆNITIS, in *Botany*, from *τανία*, a *ribband*, or *fillet*, because of the long narrow shape of the frond.—Swartz Fil. 24. Willd. Sp. Pl. v. 5. 135.—Class and order, *Cryptogamia Filices*. Nat. Ord. *Filices*.

Ell. Ch. Sorus linear, nearly uninterrupted, longitudinal, between the rib and outer margin of the frond. Involucrum none.

1. *T. blechnoides*. Pinnate Tape-fern. Swartz Fil. 220. Willd. n. 1. ("T. pteroides; Schkuhr Crypt. 21. t. 6." Sprengel Crypt. 411. t. 10. f. 106. *Pteris blechnoides*; Willd. Phytogr. 13. t. 9. f. 2.)—Frond pinnate; leaflets linear-lanceolate, tapering at each end, entire, smooth.—Native of the East Indies. The whole frond is from eighteen to twenty-four inches, or more in height, smooth, with a smooth, furrowed, bluntly angular stalk. Leaflets opposite, the lower ones occasionally alternate, five or six pair, equal, about five inches long, and half an inch wide in the middle. Line of fructification on each side of the mid-rib, about half way between it and the margin. We must rely on the authors cited as to the absence of an *involucrum*. See Sorus.

2. *T. furcata*. Forked Tape-fern. Willd. n. 2. (*Pteris furcata*; Linn. Sp. Pl. 1531. Swartz Fil. 95. *Lingua cervina furcata*; Plum. Fil. 122. t. 141. *Phyllitis aspera*, *furcis lineatis*; Petiv. Fil. n. 125. t. 6. f. 6.)—Frond simple, repeatedly forked, linear-lanceolate, acute, wavy; scaly beneath.—Gathered by Plumier in the woods of Hispaniola. No other botanist appears to have even seen a specimen. The root is tufted, scaly, bearing several fronds about a foot high, leafy to the very base, once or twice forked, and rather spreading, of a very thin membranous texture; of a fine green, and very smooth, in front; paler at the back, clothed with reddish pointed scales, and furnished with a black shining rib. The fructification is stationed in a sorus, or line, two or three inches long, on each side of the rib, but nearer the margin, in the upper part of each very acute lobe of the frond, the margin in that part being even, not wavy. The want of an *involucrum* is only presumed from Plumier's figure, nor do we esteem the generic character, of this species at least, to be very certain.

Dr. Swartz hints at another possible species, the *Blechnum feminudum*, Willd. Phytogr. 13. t. 8. f. 2. But if it be so, the

The genus can have little pretensions to be esteemed natural; and as Willdenow himself has not subsequently followed this hint, we presume he thought it unauthorized by his own specimen, which has the aspect of a confluent *Grammitis*.

TAENSAPAVA, in *Geography*, a river of West Florida, which runs into the Ibberville, N. lat. $30^{\circ} 19'$. W. long. $10^{\circ} 12'$.

TAFALE, a river of Africa, which runs into the sea, between the rivers Senegal and Nunez.

TAFALISGA, a town of Africa, in the kingdom of Jaaga, at the union of the Falema with the Senegal. N. lat. $14^{\circ} 42'$. W. long. $10^{\circ} 12'$.

TAFALLA, a town of Spain, in Navarre, honoured with the name of city by Philip IV. It has an university; 15 miles S. of Pamplona. N. lat. $42^{\circ} 35'$. W. long. $1^{\circ} 43'$.

TAFARA, a town of Africa, in the kingdom of Bambarra, on the Niger; 115 miles S.W. of Sego.

TAFEELALAT, a town of Africa, in Sahara; 200 miles N. of Tombuctoo. N. lat. $19^{\circ} 40'$. E. long. $2^{\circ} 15'$.

TAFELBERG, a town on the E. coast of the island of Ceram. S. lat. $3^{\circ} 20'$. E. long. $131^{\circ} 10'$.

TAFELICHTE, a mountain on the borders of Lufatia, 3540 feet above the level of the sea.

TAFFAREL, or TAFF-RAIL, in *Ship-Building*, the upper part of a ship's stern, usually ornamented with carved work, or mouldings, the ends of which unite with the quarter-pieces.

TAFFAROWY, in *Geography*, a mountain of Algiers; 13 miles S.E. of Oram.

TAFFETY, or TAFFATY, in *Commerce*, a kind of fine, smooth, silken stuff; having, usually, a remarkable lustre, or gloss.

Alamode, } the *taffetas noirs* of Lyons.

Lustring, }

Taffetas noir lustre of the French, is our *alamode*.

Non lustre is our *lustring*.

There are taffeties of all colours; some plain, others striped with gold, silver, silk, &c. others checquered, others flowered, others in the Chinese point, others the Hungarian; with various others to which the mode, or the caprice of the workmen, gives such whimsical names, that it would be as difficult, as it is useless, to rehearse them: besides, that they seldom hold beyond the year in which they first rose. The old names of taffeties, and which still subsist, are, taffeties of Lyons, of Spain, of England, of Florence, of Avignon, &c.

The chief consumption of taffeties is in the summer-dresses for women, in gowns, linings, window-curtains, &c.

There are three things which contribute chiefly to the perfection of taffeties, *viz.* the silk, the water, and the fire. The silk is not only to be of the finest kind, but it must be worked a long time, and very much before it be used: the watering is only to be given very lightly, and seems only intended to give that fine lustre, by a peculiar property not found in all water: lastly, the fire, which is passed under it to dry the water, has its particular manner of application, on which the perfection of the stuff depends very much.

Octavio May, of Lyons, is held the first founder of the manufacture of glossy taffeties; and tradition tells us the occasion of it. Octavio, it seems, going backwards in the world, and not able to retrieve himself by the manufacture of taffeties, such as were then made, was one day musing on his misfortunes, and, in musing, chanced to chew a few hairs of silk which he had in his mouth: his reverie being over, the silk he spit out seemed to shine, and, on that account, engaged his attention. He was soon led to reflect on the reason; and, after a good deal of thought, concluded,

that the lustre of that silk must come, 1. From his having pressed it between his teeth. 2. From his having wetted it with his saliva, which had something glutinous in it. And, 3. From its having been heated by the natural warmth of his mouth. All this he executed upon the next taffeties he made, and immediately acquired immense riches to himself, and to the city of Lyons the reputation it still maintains, of giving the gloss to taffeties better than any other city in the world.

It will not, we conceive, be less useful than curious, to insert here the description of the engine contrived by Octavio to give the gloss to taffety; and to add the manner of applying it, and the composition of the water used in it.

The machine is much like a silk-loom, except that, instead of iron points, here is used a kind of crooked needles, to prevent the taffety from slipping: at the two extremities are two beams, on one of which is rolled the taffety to take the gloss; and on the other, the same taffety, as fast as it has received it. The first beam is kept firm by a weight of about two hundred pounds, and the other turned by means of a little lever passing through mortises at each end. The more the taffety is stretched, the greater lustre it takes: care, however, is to be used that it be not weakened by over-stretching.

Besides this instrument for keeping the stuff stretched, there is another to give it the fire: this is a kind of carriage, in form of a long square, and of the breadth of the taffeties: it moves on trundles, and carries a charcoal fire under the taffety, at the distance of about half a foot.

These two machines prepared, and the taffety mounted, the lustre is given it by rubbing it gently with a ball, or a handful of lints of fine cloth, as it rolls from one beam to the other; the fire, at the same time, being carried underneath it to dry it. As soon as the piece has its lustre, it is put on new beams to be stretched a day or two; and the oftener this last preparation is repeated, the more it increases the gloss.

For black taffeties, the gloss is given with double beer and orange or lemon-juice; but this last is the least proper, as being apt to whiten them. The proportion of the two liquors is, a gallon of orange-juice to a pint of beer, to be boiled together to the consistence of a rich broth. For coloured taffeties, they use gourd-water distilled in an alembic.

There are also several different sorts of taffeties manufactured in China; as corded taffeties, which wear well; and also some with flowers, and others beautifully striped; and a particular taffety, of which they make drawers, and other kinds of wearing apparel. This last is thick, and yet so pliant, that it may be folded and pressed with the hand, without leaving any mark in it. They also wash it, like other stuffs, without its losing much of its lustre. The Chinese workmen give the lustre to this taffety with the fat of the river-porpoise, which they purify by washing and boiling; and then with a fine brush, they give the taffety two beds in the same direction, on the side which they intend to render glossy.

TAFFI, ANDREA, in *Biography*, was one of those early masters to whom the revival of the arts in Italy is attributed. His share lay in the practice of mosaic painting, which he learned of a Greek monk, named Apollonius, who had been called to Venice to work in the great church of St. Marco; and who afterwards accompanied Taffi to Florence. Andrea was born at Florence in the year 1213, and died there at the age of 81.

TAFILET, or TAFIILT, in *Geography*, a district, formerly a kingdom of Africa, is the empire of Morocco, and country

country of Biledulgerid, extending along the east side of mount Atlas; the habitations of which are about 1500 scattered houses, and of these several are defended by a tower, and each of them stands amidst an inclosure of gardens, cultivated grounds, and plantations of palm-trees, forming a variegated and pleasant country, intersected by many rivers and rivulets, descending from the east of mount Atlas, and serving to water their lands. Tafilet, as well as Draha, produces a superior breed of goats, and a great abundance of dates, which are small, but good, constituting the wealth of the country, and supplying food for the people, and even for the cattle. Although the Koran prohibits the use of spirituous liquors, yet by ancient custom, brandy is made at Tafilet of dates, which is very strong, and drunk so immoderately by the sherifs, that wine produces no effect upon them. Most of these sherifs are poor, and employ themselves in their grounds and gardens, and very frequently pillage one another. The countries situated near the banks of the rivers of Draha and Tafilet have several plantations of Indian corn, rice, and indigo. The town of Tafilet, after which the kingdom was named under the sherifs of the reigning house, is not an ancient city. It derives its name from the word "Fileli," which denominates the inhabitants of the country, and also the stuffs and carpets which are here manufactured. The soil of the extensive plain on which it is situated is a whitish clay, which when moistened resembles soap; and though it passes a river that rises in the Atlas, and pursues a course from the S.W. to the N.E., being at Tafilet about as wide as the Thames at Putney, its water, traversing the saline plains, is brackish: after a course of about 450 miles, it is absorbed in the desert of Angad. It has several castles of tarrace on its banks, inhabited by the sherifs or princes of the reigning family of Morocco. Wheat and barley have been lately cultivated near the river and the castles. Another river of inferior note rises in the plains N. of Tafilet, and flowing in a southerly direction, is absorbed in the Great Desert or Sahara. The water of this river is also brackish, and unfit for culinary purposes. The inhabitants of this country, it is said, possess such a sense of honour, that a robbery is scarcely known among them, though they use no locks. Commercial transactions are carried on amongst them by barter or exchange, so that they have little specie; but in all transactions of magnitude, gold-dust is the circulating medium. They live in the simple patriarchal manner of the Arabs, differing from them only in having walled habitations, which are invariably near the river. The climate during a great part of the year is intensely hot, and the shume, or hot wind from Sahara, blowing tempestuously in July, August, and September, and carrying with it particles of earth and sand, is very pernicious to the eyes of the inhabitants. A considerable trade is carried on from Tafilet to Tombuctoo, Houssa, and Jimme, S. of Sahara, and also to Morocco, Fez, Sufe, Algiers, Tunis, and Tripoli. Indigo abounds, but by reason of the indolence of the cultivators, it is of inferior quality. Here are also mines of antimony and lead-ore. The common dress consists of a loose shirt of blue cotton, with a shawl or belt round the waist. A caravan passes annually from hence to Tombuctoo. Woollen haks, of a curious texture, being light and fine, are manufactured here. The Tafilet goats are very prolific, and afford a rich milk in great abundance: and therefore they constitute an article of considerable export. The Tafilet leather is very soft and fine, and much superior to that of Morocco: it is as soft and pliable as silk, and impervious to water. The tanners use the leaves of a shrub called tèzra, which grows in the Atlas mountains, to which some have ascribed the peculiar quality of

the leather; though others ascribe it to some quality in the air and water. The population of the district of Tafilet is stated by Mr. Jackson at 650,000. The town is 140 miles E.S.E. of Morocco. N. lat. 31° 20'. W. long. 6°.

TAFNA, a river of Algiers, which runs into the Mediterranean, near Tackumbreet.

TAFO, or TAFA, a town of Africa, on the Gold Coast.

TAG, or TAGGE, in *Rural Economy*. See TEG.

TAG, or *Tag-Sore*, a disease in sheep, which consists, as stated in a paper in the third volume of the "Transactions of the Highland Society of Scotland," of scabs and sores situated on the under side of the tail; arising, in warm weather, from its being fouled with purging and other discharges. The matter hardens there, irritates the tender vessels, and produces sores, which, if not attended to, run into mortification, and prove fatal, as in the legs. See SWELLING or *Leg-Evil*.

It is shewn by the sheep turning frequently round to bite the tail.

As this complaint arises principally from purging, and the raltiness caused by it, &c. the first thing to be done is the restraining and cure of this evacuation: after which the tail of the animal is to be clipped, and the fore part laid bare, washed carefully with milk and water, blood-warm, and then with lime-water. The sheep is then to be turned out into a dry pasture, and looked at again in two or three days, and if not then well, the washing must be repeated, and the parts anointed with grease and tar mixed together in equal proportions.

TAGABONA, in *Geography*, a river of West Florida, which runs into the St. Mark, N. lat. 30° 22'. W. long. 84° 34'.

TAGADEMPT, TAGADEONT, or *Tigedent*, a town of Algiers, anciently called *Vaga*; 60 miles E.S.E. of Oran.

TAGÆ, in *Ancient Geography*, a town of Asia, in Parthia, near the river Oxus, and on the confines of Hyrcania.

TAGAI, in *Geography*, a town of Russia, in the government of Simbirsk; 48 miles W. of Simbirsk. N. lat. 54° 20'. E. long. 47°.

TAGAL, a town of the island of Java, on the N. coast, the residence of a Dutch agent for the purchase of rice; 35 miles E. of Cheribon.

TAGALA, *Tā-Gāla*, or *Gala* language, is among the Philippines what the Malayu is in the Malay islands, or the Hindostani in Hindostan Proper. It possesses the combined advantages of the four principal languages in the world: it is mysterious as the Hebrew; it has articles for nouns, both appellative and proper, like the Greek; it is elegant and copious as the Latin; and equal to the Italian, as the language of compliment or business. This language has been cultivated only by the Spanish missionaries. The Tagala grammar of Fra. Gaspar de San Augustin, was printed in 1703, and again in 1787. The alphabet consists of seventeen letters, three of which are vowels, and fourteen consonants. The Tagala characters are said to have been derived from the Malays, and they are read with as much difficulty as the ease with which they are written. This Tagala is written with an iron style on bamboos and palm-leaves, and the Spanish missionaries assert, that the ancient mode of writing was from top to bottom, like the Chinese. This language, with a considerable number of peculiar vocabularies, and great singularity of idiom, is nevertheless to be considered as a cognate language with Malayu, Bujis, and Javanese. Few languages, on a cursory examination, present a greater appearance of originality than the Tagala.

For a farther account of it, we refer to Dr. Leyden's Essay on the "Languages and Literature of the Indo-Chinese Nations," in the Asiatic Researches, vol. x.

TAGALAZ, in *Geography*, one of the Fox islands, in the North Pacific ocean. N. lat. 53° 30'. E. long. 185° 26'.

TAGAMA, in *Ancient Geography*, a town of Africa, in the interior of Libya, upon the bank of the Niger. Ptol.

TAGAMA, in *Geography*, a country of Africa, in Nigritia. W. of Caffra.

TAGANROG, a fort of Russia, on the sea of Azoph, first built by Peter the Great in 1696; 32 miles W.N.W. of Azof.

Taganrog is situated upon the cliff of a very lofty promontory, commanding an extensive prospect of the sea of Azof, and the whole European coast to the mouths of the Don. The number of inhabitants does not at present exceed 5000. The mole in the haven is so shallow, that ships performing quarantine lie off at the distance of 10 miles, and all vessels drawing from 9 to 10 feet of water cannot approach nearer to the town than this distance. This town has sunk into decay; and all the best houses are in its suburbs. If it had water, its situation is very favourable for commerce; but it can be carried on here only for three months in the year. In the winter the sea is frozen. Here are three fairs in the year. The fish caught in great abundance in the sea of Azof is dried and sent over all the north of Russia. Fruit is brought from Turkey, such as figs, raisins, and oranges; Greek wine from the Archipelago, with incense, coffee, silk, shawls, tobacco, and precious stones. Copper of a very inferior quality comes from Trebizond, and is forwarded to Moscow. Among the principal exports are caviare, butter, leather, tallow, corn, fur, canvas, rigging, lines, wool, hemp, and iron. The greatest advantage this town enjoys is its being the depository of Siberian productions. The Calmucks form large settlements in the vicinity of Taganrog. It is the resort of people from a great variety of countries; inasmuch that the inhabitants of fifteen different countries have been observed in this place at the same time.

TAGAPOLA, a small island among the Philippines; 25 miles W. of the island of Samar.

TAGARA, an ancient city of India, known to the Greeks about 2050 years ago. Arrian, in his *Periplus Maris Erythraei*, says that it was a large city, and all kinds of mercantile goods throughout the Deccan were brought hither, and hence conveyed in carts to Baroach, or Barygaza. Arrian also informs us that Tagara was situated at about 10 days' journey E. of another famous mart, called Pluthana, or Pluthana; that Pluthana was 20 days' journey S. of Baroach; and that the road to it was through the Bala-gaut mountains. Pluthana, now called Pultanah, is situated on the southern bank of the Godavery, about 217 British miles to the southward of Baroach. If we divide these 217 miles by 20, the number of days travellers spent in passing from between Pultanah and Baroach, according to Arrian, we shall have nearly 11 miles *per* day, or 5 cofs, which is the usual rate of travelling with heavy loaded carts. Arrian informs us, that Tagara was about 10 days' journey W. of Pultanah. Allowing these 10 days to be equal to about 100 British miles, Tagara, by its bearing and distance from Pultanah, falls at Deoghire, or Deogire (which see), a place of great antiquity, and famous through all India, on account of the pagodas of Eloura. It is now called Dowlatabad, and about four cofs N.W. of Aurungabad. It appears in Arrian's *Periplus*, that on the arrival of the Greeks

into the Deccan, above 2000 years ago, Tagara was the metropolis of a large district called Ariaca, which comprehended the greatest part of subah Aurungabad, and the southern part of Concan. About the middle of the first century, Tagara was no longer the capital of Ariaca, rajah Salbahan having removed the seat of the empire to Pattan. However, the rajahs, headed by Salbahan, having revolted, they gave him battle, and he was slain. Tagara became again the metropolis of Ariaca; at least this was the case towards the latter end of the eleventh century. When the Mussulmans carried their arms into the Deccan, about the year 1293, Tagara or Deoghir was still the residence of a powerful rajah, and remained so till the time of Shah-Jehan, when the district belonging to it became a subah of the Mogul empire. Thus Tagara was deserted, and Kerkhi, four cofs S.E. of it, became the capital, now called Aurungabad. Thus the ancient kingdom or rajahship of Tagara was destroyed, after it had existed, with little interruption, above 2000 years. Asiatic Researches, vol. i.

TAGASA, a town of Fez, seated on a river about three leagues from the Mediterranean; 20 miles W. of Melilla.

TAGASTA, in *Ancient Geography*, a town of Africa, in Numidia, on the route from Hippone to Cæsarea. Anton. Itin.

TAGAVAST, in *Geography*. See TAGOAST.

TAGAZEE, a town of Africa, on the road from Mourzouk to Agades; 260 miles S. of Mourzouk. N. lat. 23° 32'. E. long. 12° 55'.

TAGAZOUTE, a town of Algiers; 45 miles S.E. of Oran.

TAGEBACHI, an island in the Red sea. N. lat. 25° 2'.

TAGETES, in *Botany*, a name which Fuchsius tells us is applied by Apuleius to the Tanfy, but which he himself adopts for a plant, not very dissimilar in foliage, now vulgarly called the French, or African, Marygold. He is followed by Dillenius, Linnaeus, and every subsequent writer. De Theis derives the word from Tages, an Etruscan deity, grandson of Jupiter, and teacher of divination; and supposes the beauty of its flowers may have procured the plant this mythological appellation. Of this intention we can find no traces in the above writers.—Linn. Gen. 430. Schreb. 561. Willd. Sp. Pl. v. 3. 2126. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 88. Tourn. t. 278. Juss. 182. Lamarck Illustr. t. 684. Gærtn. t. 172.—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ oppositifoliae*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Common calyx* perfectly simple, of one leaf, tubular, oblong, with about five teeth, and as many longitudinal angles. *Cor.* compound, radiant. Florets of the elevated disk numerous, all perfect, tubular, longer than the calyx, erect, cut half way down into five linear segments, villous at the inside: those of the radius five, ligulate, female, longer than those of the disk, their limb almost as broad as long, very obtuse, contracted and downy towards the tube, permanent. *Stam.* in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in the perfect florets, Germen oblong; style thread-shaped, the length of the stamens; stigma divided, slender, reflexed. *Peric.* none, the calyx remaining unchanged. *Seeds*, to both kinds of florets, solitary, linear, compressed, rather shorter than the calyx; crowned with five, more or less, erect, pointed, unequal scales. *Recept.* naked, small, flat.

Obsl. In a cultivated state, the two common garden species have usually, from luxuriance, more segments in the calyx,

TAGETES.

calyx, and more florets in the radius, than is natural; one of these luxuriant flowers is what Gærtner has delineated. Some more recently discovered species, on the other hand, have naturally but three or four radiant florets.

Eff. Ch. Receptacle naked. Seed-down of several erect pointed scales. Calyx simple, of one leaf, tubular, with five teeth. Florets of the radius five, permanent.

1. *T. patula*. French Marygold. Linn. Sp. Pl. 1249. Willd. n. 2. Ait. n. 2. Loureir Cochinch. 504. Curt. Mag. t. 150. (Flos aphricanus minor, simplici flore; Ger. Em. 750. Caryophyllus indicus minor; Camer. Epit. 407.)

β. *T. minor*, flore fulvo maculato; Dill. Elth. 373. t. 279.—Stem spreading. Leaves pinnate; leaflets lanceolate, with hair-pointed ferratures. Stalks single-flowered, somewhat swelling upwards.—Native of Mexico, from whence it was brought to the gardens of Europe, about the middle of the sixteenth century, and hence dispersed over other countries, being now, according to Loureiro, commonly cultivated in Cochinchina, China, and various parts of India. With us it is a tender annual, raised on a hot-bed in spring; and being planted out after midsummer, decorates almost every garden throughout the autumn. Its appellations of French Marygold, and African Flower, are altogether founded in error. The stem is about a foot or 18 inches high, branched and widely spreading. Leaves opposite, of five or six pair of dark green shining leaflets, with an odd one; all gradually smaller downwards. Flowers about two inches in diameter, yellow, with broad lateral stripes, or spots, to each radiant floret, of a peculiarly rich brown. They vary in size and tints, as well as scent, and are generally more or less double. The plant of Dillenius hardly deserves to be marked as a variety. The herb when bruised is very fetid, acrid, and supposed to be poisonous, though too nauseous to be very dangerous. Few flowers are more striking in appearance.

2. *T. erecta*. African Marygold. Linn. Sp. Pl. 1249. Willd. n. 3. Ait. n. 3. (Flos aphricanus major; Ger. Em. 749. Caryophyllus major indicus; Bess. Elyset. æst. ord. 14. t. 2. C. indicus; Camer. Epit. 406.)—Stem erect. Leaves pinnate; leaflets lanceolate, with hair-pointed ferratures. Stalks single-flowered, swelling upwards.—Native of Mexico; introduced into the gardens of Europe about the same time as the foregoing, nor is the epithet of African more correctly applied to one than to the other. The same mode of culture suits both, and both are equally common. This species is much the tallest, and grows erect. The leaves are rather paler. Flowers twice as large, of a golden uniform yellow; sometimes orange-coloured. Columna, in his *Ephraisi*, part 2. 47. t. 46, represents a quilled variety, as it is termed, whose radiant florets are funnel-shaped, and another whose florets are all of that sort.

3. *T. elongata*. Long-stalked American Marygold. Willd. n. 4.—Stem erect, nearly simple. Leaves pinnate; leaflets linear, serrated at the end; those of the lower leaves wedge-shaped. Stalks single-flowered, elongated, slightly swelling.—Native of South America. Root annual. Stem from three inches to a span high, either simple, or furnished with a branch or two from the bottom. Leaflets of the lower leaves obovato-lanceolate, serrated at the extremity; those of the upper linear, with a few slightly hair-pointed ferratures at the end. Stalk solitary at the top of the stem or branch, and almost as long as the stem itself. Flower deep yellow, agreeing in form and structure with *T. patula*.

4. *T. minuta*. Small-flowered Chili Marygold. Linn. Sp. Pl. 1250. Willd. n. 5. Ait. n. 4. (*T. multiflora*, minuto flore albicante; Dill. Elth. 374. t. 280.)—Stem

erect; densely panicled. Leaves pinnate; leaflets lanceolate, serrated. Stalks many-flowered, scaly.—Native of Chili. Cultivated in Dr. Sherard's garden, before the year 1728. A hardy annual, flowering in autumn, but seldom preserved in collections. The stem is ten or twelve feet high, covered with leaves, which are smaller than those of the first species. The flowers are very small and pale, forming dense, compound, tufted, erect panicles, at the ends of the branches; their stalks clothed with bristly scales. Calyx cylindrical. Radius of two, three, or four variously lobed florets. This is surely the Chili plant of which Feuillé (quoted by Dillenius) describes two varieties, differing in the number of their radiant florets; and which he says is extremely hot in quality. The Indians eat it to warm themselves after their return from fishing.

5. *T. caracasana*. Long-stalked South American Marygold. Willd. n. 6. (*T. peduncularis*; Cavan. Leccion. 201. n. 494?)—"Stem corymbose, furrowed, erect. Leaves pinnate; leaflets lanceolate, serrated at the end. Stalks elongated, single-flowered, erect. Calyx cylindrical."—Gathered by Baron Humboldt at the Caraccas.—Root annual. Stem corymbose at the top. Leaflets linear-lanceolate, serrated at the end, not fringed. Flowers like those of the next species, on long alternate stalks. Leaflets of the uppermost leaves entire. Willdenow. The plant of Cavanilles was raised in the garden at Madrid, from seeds collected at Cumaná by Bonpland, the companion of the celebrated Humboldt. The stem is described a foot and a half high, furrowed, much branched. Flower-stalks six inches long, tumid near the calyx, leafy in their lower part. Corolla entirely yellow, with six or eight rays shorter than in the following. We find nothing in his account which is not conformable to the plant before us, and should have been glad if we could have adopted his greatly preferable specific name.

6. *T. tenuifolia*. Fine-leaved Peruvian Marygold. Cavan. Ic. v. 2. 54. t. 169. Willd. n. 7. Ait. n. 5.—Stem panicled. Leaves pinnate; leaflets linear, serrated; their lower ferratures elongated. Stalks alternate, single-flowered. Calyx club-shaped.—Native of Peru. Cavanilles. We have specimens from Mutis. Mr. W. Malcolm is said in Hort. Kew. to have cultivated this species in 1797, but being a late-flowering annual, greatly inferior in size and beauty to the popular species of the same genus, it has probably not been preserved. The appearance of the dried specimens is like a starved *T. patula*, with more numerous, much smaller, flowers than usual. The calyx abounds with oblong glandular dots, of which traces are likewise found in that species. The corolla is described of a full unspotted yellow.

7. *T. elliptica*. Oval-leaved Peruvian Marygold.—Stem erect, branched. Leaves pinnate; leaflets elliptical, with shallow ferratures. Stalks corymbose, with lanceolate bracteas.—Native of Peru. We received a dried specimen from the late abbé Cavanilles, in 1804. The stem has a shrubby appearance, and is much branched, leafy and furrowed. Leaflets scarcely visibly serrated, pointed, smooth and even; the lower ones of each leaf gradually smaller, and mostly alternate. Flowers rather numerous, not very much smaller than in *T. patula* when not luxuriant; their partial stalks accompanied by alternate lanceolate bracteas. Calyx marked with scattered, apparently glandular, lines. This is certainly very distinct from all the species we can find described.

8. *T. micrantha*. Small-flowered Mexican Marygold. Cavan. Ic. v. 4. 31. t. 352. Willd. n. 8.—Stem much branched, spreading. Leaves pinnate; leaflets linear-awl-shaped, entire. Stalks axillary, single-flowered.—Gathered by

Louis

Louis Née, near the town of Querétaro, in New Spain. It flowered in the Madrid garden, in October 1796. *Root* annual. *Stems* hardly a foot high, round, rather woody, smooth like every other part of the plant. The slenderness of the *leaves*, and smallness of the *flowers*, give this species the appearance of a PECTIS or HETEROSPERMUM (see those articles); but the *calyx* is perfectly simple, tubular, with five furrows and five teeth. *Florets* of the radius two only, whitish and undivided: those of the disk generally five, yellow, scarcely more than four-cleft. *Seeds* long, compressed, each crowned with two bristles, and two intermediate, notched, unequal scales.

9. *T. lucida*. Sweet Chili Marygold. Cavan. Ic. v. 3. 33. t. 264. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 740. Andr. Repof. t. 359.—*Leaves* simple; finely serrated. *Panicle* corymbose.—Native of New Spain. Its seeds were brought to England in 1798, by the late marchioness of Bute, along with many other novelties from the gardens of Madrid. The *root* is perennial, and will endure our ordinary winters, with a slight degree of protection. *Stem* erect, about two feet high, round, striated, leafy, smooth; branched in the upper part. *Leaves* one and a half or two inches long, opposite, on short, broad, combined *footstalks*, elliptic-oblong, smooth, veiny, full of pellucid dots; their lower serratures tipped with bristly points, or hairs. *Panicle* level-topped, many-flowered; its stalks angular, smooth, with linear-lanceolate *bracteas*. *Calyx* half an inch long, besprinkled with glandular dots. *Flowers* of a golden yellow, agreeably scented; their radiant *stamens* generally three, very broad. *Seed* crowned with from two to five linear-lanceolate unequal scales. The serratures of the *leaves* are very incorrectly represented in Cavanilles's plate, where they are made to resemble a fringe of fine hairs, which only belongs to the lower ones, and is not expressed in any of the figures hitherto published.

TAGETES, in *Gardening*, furnishes plants of the herbaceous annual kind, among which the species mostly cultivated are, the French marygold (*T. patula*), and the African marygold (*T. erecta*).

The first sort has several varieties, as the pale yellow-flowered, deep yellow-flowered, golden yellow-flowered, crimson-coloured, velvety, variegated crimson and yellow, striped crimson and yellow; each of which has both single and double flowers: and there are the large-flowered, small-flowered, sweet-scented, and the dwarf French marygolds.

In the second sort, also, there are varieties; as those with pale yellow or brimstone-coloured flowers, with deep yellow flowers, with orange-coloured flowers; the sweet-scented and the dwarf, &c.; each with single, double, and fistulous flowers; the middling African, with orange-coloured flowers, and the sweet-scented African, and perhaps some others.

Method of Culture.—All these plants are increased by seeds, which should be sown in the beginning of April upon a hot-bed; and when the plants appear, they should have plenty of fresh air, and, after they have attained some growth, be transplanted on to another hot-bed, which is arched over by hoops, at the distance of six inches; watering and shading them well till fresh-rooted, being afterwards gradually inured to the open air; and about the beginning of May they may be taken up with balls of earth about their roots, and be planted in pots, to be set out in the courts, yards, &c. about the house, shading them till fresh rooted, and giving them water occasionally. But the first sort divides and spreads out widely near the ground, in a rambling manner, and requires to be trimmed up at bottom to a single stem, and its branches occasionally, to preserve the head somewhat regular, and within due bounds.

VOL. XXXV.

In raising them in the open ground, in case of the default of hot-beds and other conveniences, the seed should not be sown before the beginning of April, when the plants are to be covered and protected in the nights, and in severe weather; and when otherwise, not until the middle or latter end of it, and then in a warm rich situation, either in drills of half an inch in depth, or on the surface, and raked in lightly. After the plants are a few inches high, they should be planted out either finally into the borders and other parts, or, when too small, into nursery-rows for a little time, and then set out where they are to remain.

Two or three plants may be placed nearly together, in patches at five or ten feet distance; and when they shew their flowers, so as to judge of their properties, the worst may be cleared away, and one only of the best left to each patch, &c. The same way may be had recourse to in planting in pots, &c.

In the future culture of all these kinds of plants, occasional waterings are necessary, frequently the first and second weeks after planting out, but more seldom afterwards. Those in pots should have it three times in the week constantly, and morning and night in very hot weather.

Stakes are requisite to the strong large-headed plants, one to each. They should also be properly trimmed in their side-branches near the bottom, and the too great ramblers, to produce regularity.

However, the second species in particular, and the varieties of it, as they always grow firmly erect, both in stem and branches, require but very little trouble after their final planting out: they afford ornament and variety, among other plants, in the borders, clumps, and other parts of pleasure-grounds, as well as in pots for particular places about the house, among other potted annual plants. The seeds of each species, and their varieties, should be annually saved from the best plants.

All the sorts grow very well and freely in any common garden soil, which is in an open exposure, exhibiting a particularly conspicuous autumnal bloom, in long succession; and when properly arranged, and disposed in assemblage with other sorts of plants, afford a highly ornamental variety and effect, in the great diversity of the various forms and colourings of the flowers, in the different sorts and varieties.

In saving the seed, it should be collected only from the finest and fullest double flowers, when perfectly ripe, keeping that of the different varieties quite distinct. The prime large heads of seed of each sort, after being well dried, may either have the seed beat and rubbed out, or kept in them, putting the whole up into bags, boxes, or drawers, until the period of putting them into the ground. Fresh seed should constantly be saved every year, as that of more than one year old will seldom grow well.

TAGGAH, in *Geography*, a town of Africa, in the country of Algiers; 24 miles S.E. of Seteef.

TAGGIA, a town of the Ligurian republic; 4 miles N.E. of St. Remo.

TAGGING. See SHEARING.

TAGHAYOOG BAY, in *Geography*, a bay on the west coast of the island of Paraguay. N. lat. 25° 2'.

TAGHMOM, a post-town of the county of Wexford, Ireland, on the road from New Ross to Wexford, which was a borough before the union, and sent two members to the house of commons. It is 73 miles S. by W. from Dublin, and about 9 W. from Wexford.

TAGIA, a small island in the bay of Cunong-Tellu, on the east coast of Celebes. S. lat. 0° 30'. E. long. 122° 6'.

TAGIABAD, a town of Persia, in the province of Irak; 15 miles E. of Natens

TAGILSKOI, NIZNEI, a town of Russia, in the province of Ekaterinburg; 60 miles N. of Ekaterinburg.

TAGIOURA, a town of Africa, in the country of Tripoli; 10 miles E. of Tripoli.

TAGLARET, a town in the department of the Po; 7 miles W. of Pinerolo.

TAGLIACOZZI, or **TALIACOTIUS, GASPARO**, in *Biography*, was born at Bologna in 1546, and practised with celebrity as a physician and surgeon in his native city from the year 1570 to 1599, where he died. The peculiar practice, implied in his name, was that of restoring lost parts by insinuation; and this practice he derived from some Neapolitan and Sicilian surgeons. It was founded on the principle, that two raw surfaces of living bodies or parts, attached to each other in close contact, will adhere and mutually transmit circulating fluids. On this subject he published two treatises: *viz.* "Epistola ad Hieronymum Mercurialem de Naribus, multo ante abscissis, reficiendis," Francof. 1587; and "De Curtorum Chirurgia per Insitionem, Lib. duo, additis Cutis traducis, Instrumentorum omnium, atque Deligationum, iconibus et tabulis," Venet. 1597, fol. A similar practice has anciently prevailed in India, and is now occasionally adopted after the common punishment of amputating the nose; for restoring which, a piece from the skin of the forehead is ingeniously engrafted. Modern surgeons have availed themselves of the principle, by bringing over flaps of the adjacent skin, in order to accelerate the healing after amputation, and other operations. Haller. Eloy. Gen. Biog.

TAGLIACOZZO, in *Geography*, a town of Naples, in Abruzzo Ultra; 18 miles S.W. of Aquila. N. lat. 42° 4'. E. long. 13° 19'.

TAGLIATO, Ital., in *Music*, is used for measure, which the French call *barré*; that is, when the character for common time is thus marked, $\frac{C}{\parallel}$, or $\frac{C}{\text{C}}$, with a perpendicular line drawn through the middle of the C; it implies quick time, in which the notes are played or sung twice as rapidly as in the usual common time; a semibreve being performed like a minim, a minim like a crotchet, a crotchet like a quaver, &c. A *breve*, double the length of a semibreve, used to fill a bar; whence the terms *alla breve*. This time is still used in music *à capella*, and *alla Palestrina*; in which the notes being chiefly open, and in fugue, musicians usually call a fugue consisting chiefly of semibreves and minims a *white fugue*. The time, too, when a line is drawn through the C, is called *cut time*.

TAGLIER, in *Geography*, a small island in the gulf of Venice. N. lat. 44° 10'. E. long. 15° 17'.

TAGLIO, a river of the Ligurian republic, which runs into the Mediterranean, 4 miles E. of St. Remo.

TAGLIO BAY, a bay on the south coast of the island of Mindanao. N. lat. 6° 8'. E. long. 125° 40'.

TAGLO Point, a cape on the north-west coast of Mindanao.

TAGNON, a town of France, in the department of the Ardennes; 8 miles S.W. of Rethel.

TAGOAST, TAGAOST, or *Tagavast*, a large town of

Africa, in the kingdom of Sus; said by some to have been the birth-place of St. Augustine; situated in a fertile country, and defended by a garrison of 400 men; 140 miles S.W. of Morocco.

TAGODAST, a town of Morocco, near the foot of mount Atlas; 60 miles N.E. of Morocco.

TAGOLANDE, an island in the East Indian sea, about 10 miles in circumference. N. lat. 2° 18'. E. long. 125° 6'.

TAGOMAGO, a small island in the Mediterranean, near the east coast of the island of Iviça.

TAGORA, in *Ancient Geography*, a town of Africa, in Numidia. Anton. Itin.

TAGOURIE, in *Geography*, a town of Chinese Tartary, in the province of Hami; 40 miles N.N.E. of Hamtam.

TAGOU-ZAINAH, the towns of Taggah and Zaina in Algiers, being contiguous, and separated only by a small brook; 50 miles S.W. of Constantina.

TAGTE-RUSTAN, a mountain of Persia, very much resorted to by the Gentoos; 4 miles from Ispahan.

TAGTESSA, a town of Morocco; 120 miles W.N.W. of Morocco.

TAGUA, a town and also district of Africa; 250 miles N.E. of Bornou. N. lat. 19° 10'. E. long. 27° 20'.

TAGUAN, in *Zoology*. See *SCIURUS Petaurisla*.

TAGULMEMMET, in *Geography*, a town of Algiers; 5 miles S.E. of Mustygannim.

TAGULO, a town on the south coast of the island of Mindanao. N. lat. 7° 30'. E. long. 124°.

TAGUMADERT, a town of Africa, in the country of Darah; 20 miles S. of Tattah.

TAGURIN, a town on the west coast of the island of Luçon. N. lat. 16° 20'. E. long. 120° 48'.

TAGUS, or **TAGO**, a river, which rising in the mountains of Molina, that separate the kingdom of Aragon from Old Castile, passes by Aranjuez, Toledo, Talavera de la Reyna, crosses Castile and Estremadura, and enters Portugal at Montalvao; traversing Estremadura, it passes by Abrantes, Santarem, &c. and runs into the Atlantic about 10 miles below Lisbon. Its current is broken by many cataracts, so that on this account, and also on account of its rocks, it is not navigable far above Lisbon.

TAGYPEEL, a small island in the East Indian sea, near the N.E. coast of Borneo. N. lat. 6° 29'. E. long. 117° 54'.

TAGZA, a town of Algiers; 12 miles S.S.E. of Constantina.

TAHA el Modain, a town of Egypt; 5 miles S.W. of Samalut.

TAHABUCKOO, a town of Thibet; 5 miles N.W. of Jhanfu-Jeung.

TAHAIS, a town of Sweden, in the province of Savolax; 50 miles N.N.W. of Nyfot.

TAHAL, a town of Spain, in the province of Grenada; 8 miles N.N.E. of Purchena.

TAHATE, a town of Arabia, in Yemen; 12 miles W. of Zabid.

TA-HEAN, a city of China, of the second rank, in Yun-nan; 1130 miles S.W. of Peking. N. lat. 25° 52'.

TAHEJ, a town of Hindoostan, in Cutch; 150 miles W. of Amedabad. N. lat. 23° 16'. E. long. 69° 58'.

TA-HE-KAN, a small island near the coast of China. N. lat. 37° 57'. E. long. 120° 30'.

TAGHUM, a town of Bengal; 14 miles W. of Koonda.

TAHIAO, a town of Corea; 35 miles S.S.E. of Long Kouang.

TAHIRAN, a town of Persia, in the province of Irak; 45 miles E.S.E. of Casbin. N. lat. $35^{\circ} 50'$. E. long. 51° .

TAHNUM, a town of Gorkah; 20 miles N.W. of Gorkah.

TA-HOOROWA, one of the smaller Sandwich islands, situated about nine miles from the S.W. part of Mowee; destitute of wood, with a sandy, barren soil. N. lat. $21^{\circ} 40'$. E. long. $199^{\circ} 30'$.

TAHOU, a town of Africa, on the Grain Coast. N. lat. $4^{\circ} 50'$. W. long. $6^{\circ} 50'$.

TAHRIE', a town of Persia, in Farfistan, on the coast of the Persian gulf; 12 miles E.S.E. of Konkum. N. lat. $27^{\circ} 45'$. E. long. $52^{\circ} 20'$.

TAHTA, a town of Egypt, on the Nile; 32 miles S. of Siut. N. lat. $26^{\circ} 57'$. E. long. $31^{\circ} 22'$.

TAHUK, or **TABUK**, a town of Arabia, in the province of Nedsjas; 176 miles S.S.E. of Jerusalek.

TAI, a city of China, of the second rank, in Chan-fi; 175 miles W.S.W. of Peking. N. lat. $39^{\circ} 6'$. E. long. $112^{\circ} 30'$.—Also, a city of China, of the second rank, in Kiang-nan; 22 miles E. of Yang-tcheou. N. lat. $32^{\circ} 30'$. E. long. $119^{\circ} 36'$.—Also, a large lake. See **TAI-HOO**.

TAI-Arabs, an ancient and noble tribe, the mention of which often occurs in the Roman history. They still continue in possession of the same tract of country which they had in the time of Julian, viz. between Moful, Nisibin, and the Khadour.

TAJACU, or the *Sus tajacu* of Linnæus, in *Zoology*, the name of an animal common in some parts of America, called by many authors *aper moschiferus*, or the musk-boar. (See *Sus*.) It is of the shape of our hog, but much smaller, and has no tail, and its head is broader, and the snout much less pointed than in our hog; it has two tusks in each jaw, those in the upper jaw pointing down, and hardly apparent when the mouth is shut, the others hid; the neck is short and thick, and the whole body of a grisly colour, or mixture of black and grey; its body is covered with hairs, much thicker and stronger than our hog's-bristles, something like the bristles of the hedge-hog, and like them also variegated with circles of black and white; these are four or five inches long on the back, and gradually diminish to the sides; on the middle of its head, between the ears, it has a sort of crest, made up of black bristles; the belly almost naked; from the shoulders to the breast is a band of white; its ears are small and erect, and its eyes small; its snout, feet, and hoofs, are just like those of the European hog; but the two posterior or exterior hoofs are longer than in any other of the cloven-footed beasts.

What is most singular, however, in this creature, is a certain gland which he has upon the back, and which has given occasion to some to say its navel was placed there. This gland is situated on the very ridge of the back near the rump, and is so closely covered with long bristles, that till they are removed by blowing, and keeping them back with the hand, the gland is not to be seen: when these are removed, there is seen a spot almost naked, in the middle of which the top of the gland is seen; the lips of this gland usually stand a little way above the flesh, and its aperture easily admits a large stylus; and this gland, when lightly pressed, spews out a liquid substance of a brownish-yellow colour, and scent something like that of musk or civet. The gland itself is placed between the skin and flesh, and is not wholly covered by its constricting muscle, but only surrounded by it at its bottom.

This animal inhabits the hottest parts of South America, and some of the Antilles; lives in forests, on the mountains, is very fierce, and if wounded, will turn on the hunter. It feeds on fruits and roots, toads and serpents, which it skins with great dexterity. It is reckoned very good food; but unless the dorsal gland be cut out as soon as it is killed, the flesh will be infected by it. The Indians call this animal *pequaris*, whence its name *pecary*. Ray and Pennant.

TAJAMENTO, or **TAGLIAMENTO**, in *Geography*, a river which rises in Friuli, and runs into the gulf of Venice; 10 miles S.S.E. of Concordia.

TAJANJE, a river of Brafil, which runs into the Atlantic, S. lat. $27^{\circ} 35'$.

TAJARA, in *Ichthyology*. See **RAIA**.

TAIBEH, in *Geography*, a fortified town in the desert of Syria, having near its gate a fountain of fresh water; 85 miles E. S. E. of Aleppo. N. lat. $35^{\circ} 10'$. E. long. $38^{\circ} 45'$.

TAI-CHAN, a town of Corea; 20 miles W. of Haimen.

TAIDENT, a town of Africa, in Fezzan; 130 miles S.S.W. of Mourzouk.

TAJE-ELT, a town of Algiers; 35 miles S.S.E. of Bona.

TAIEZA, a town of Croatia; 45 miles E. of Bihacs.

TAIGAREE. See **TEGERLY**.

TAI-HOO, or **TAI**, a beautiful lake of China, said to be near fifty leagues in circumference, dividing the provinces of Kiang-nan and Tche-kiang, and surrounded by a chain of picturesque hills. It supplies Sou-choo-foo, at a small distance from it, with fish, and serves the inhabitants also as a place of public resort and recreation. Many of the pleasure-boats on this lake are rowed by a single female; and the rowers are said to follow more than one profession.

TAIBI, in *Zoology*, the name of an American animal, described by Marcgrave and other authors, and supposed by some to be only the male of the opossum. The Portuguese in America call it the *cachorro de mato*, and by the Dutch it is called *boschratte*. See **DIDELPHIS**.

TAIEOURA, in *Geography*, a town of Africa, in the kingdom of Adel; 15 miles N.W. of Zeilah.

TAIL, CAUDA, that part of an animal which terminates its body behind.

The tail is different, both in figure and use, in the various species. In land-animals it serves to rid them of flies, and is usually covered with hair, and strengthened with bones: in fishes it is cartilaginous, and serves them as a helm to steer their course withal in swimming.

In birds it is covered with feathers, and greatly assists in all ascents and descents in the air; as also to render their flight steady, by keeping the body upright in that subtle and yielding medium, by its ready turning and answering to every vacillation of the body.

TAIL of Fish. This part in the fish-kind is the subject of very great distinctions; among the characters of the several genera. It differs in the several kinds of fish in a very obvious manner, in number, situation, and figure. In regard to the first difference, the *acus lumbriciformis*, and one of the kinds of the *serpens marinus*, have no tail at all; in all other fish there is a tail, and it is never more than one on each fish.

In regard to situation, there is this great difference, that in some it is placed perpendicularly, in others horizontally. In almost all the known fishes it is placed perpendicularly, except in the dolphin, the phocæna, the orca, the manati, and all the whale-kinds; for in all these it is placed horizontally, when the body is laid in its natural posture.

In figure it has many very remarkable differences, which are of great use in ichthyological distinctions. 1. In some fish it is rounded at the end; as in the cottus, and some others. 2. In some it is cut off even as it were at the end, so that the whole tail is a sort of parallelogram; as in the tench, and some of the salmon. 3. In some fishes it is cuspidated at the end, as is the case in the conger, the eel, and the petromyzon. 4. In others it has as it were a small segment of a circle cut out at the end, and so is slightly hollowed out; this is the case in the carassius, and some of the salmon. 5. In many fish it is forked or opened into two points, making an acute angle: this is the figure of the tail in the perches, the cyprini of many kinds, &c. 6. Finally, the tail is falcated in many fish, that is, it is of the shape of a crescent; as in the sword-fish, the tunny, mackarel, and the like. *Artedi, Ichthyolog.*

TAIL, in *Anatomy*, is used for that tendon of a muscle which is fixed to the moveable part. In opposition to which, the tendon fixed to the immovable part is called the *head*.

TAIL, *Dove*, or *Swallow's-Tail*, among *Carpenters*. See DOVE-TAIL.

TAIL, *Peacock's*, a term applied to all circular compartments which go enlarging from the centre to the circumference; imitating, in some measure, the feathers of a peacock's tail, when spread.

TAIL, *Dragon's*, *cauda draconis*, in *Astronomy*. See DRAGON, and NODE.

The astrologers take care to put this in all their horoscopes.

TAIL, *Horse's*, among the Tartars and Chinese, is the ensign or flag under which they make war.

Among the Turks, it is the standard borne before the grand visier, the bashaws, and sangiaes; in order to which, it is fitted on the end of a half-pike, with a gold button, and is called *toug*.

There are bashaws of *one*, others of *two*, others of *three* horses' tails. The horse's tail placed on the general's tent, is a signal of battle. For the original of this custom, it is related, that in a certain battle, the standard being taken by the enemy, the general of the army, or, as others say, a private horseman, cut off the tail of his horse, and fastening it to the end of a half-pike, encouraged the troops, and gained the victory. In memory of which noble action, the grand signior appointed that standard to be borne, for the future, as a symbol of honour. *Ricaut*.

TAIL, in *Heraldry*, &c. is particularly used for the tail of a hart; those of several other creatures having peculiar and distinct names.

As, that of a buck, roe, or any other kind of deer, is called the *single*; that of a boar, the *wreath*; of a fox, the *brush*; of a wolf, the *stern*; and of a hare and rabbit, the *feut*.

TAIL of a Comet. See COMET.

TAIL, or *Toile*, in *Common Law*, signifies a limited fee, as opposite to fee-simple.

It is thus called from the barbarous word *taliare*, whence the French *tailler*, to cut; because such fee is so minced or parted, as it were, that it is not in the owner's free power to dispose of it; but is, by the first giver, cut, *taillé*, and divided from all others, and tied to the issue of the donee.

The limitation of tail is either *general* or *special*. See FEE-TAIL.

TAIL after *possibility of issue extinct*, is where land being given to a man and his wife, and the heirs of their two bodies, and the one outlives the other, without issue between them begotten: the survivor upon this shall hold the land

for term of his own life in quality of tenant in tail after the possibility of the issue extinct.

This estate must be created by the act of God, *i. e.* by the death of that person out of whose body the issue was to spring, for no limitation, conveyance, or other human act, can make it. It partakes partly of the nature of an estate-tail, and partly of an estate for life. The tenant is, really, only tenant for life, but with many of the privileges of a tenant in tail; as, not to be punishable for waste, &c.; or he is tenant in tail, with many of the restrictions of a tenant for life; as, to forfeit his estate if he aliens it in fee-simple; whereas such alienation by tenant in tail, though voidable by the issue, is no forfeiture of the estate to the reversioner; who is not concerned in interest, till all possibility of issue be extinct. But, in general, the law looks upon this estate as equivalent to an estate for life only; and, as such, will permit this tenant to exchange his estate with a tenant for life: which exchange can only be made of estates that are equal in their nature. *Blackst. book ii. &c.*

TAIL, *Fee*. See FEE-TAIL.

TAIL, *Several*. See INHERITANCE.

TAIL, or *Taille*, is also used for what we vulgarly call *tally*, *taille de bois*.

TAIL, in the *Manege*. Many affirm that the dock of a horse's tail serves to point out his sixth or seventh year; saying, that about the time that the black speck or eye of the bean begins to disappear, and the cavity to be filled, the dock of the tail becomes longer, because the vigour of the young years begins to abate; and nature has not strength enough to nourish and keep up the joints or knots that form the dock; so that when the horse is six years old, one of these joints slackens and begins to fall down; and a year after, another descends in like manner. But this relaxation or downfalling happens sooner in some than in others, according as they have been well or ill kept, with reference to feeding, housing, and working. Accordingly we find the marks of a horse's age, taken from his tail, are so erroneous, that many jockies maintain, that the first joint descends when he is nine, and the second when he is ten years old.

TAIL, *Docking of*. See DOCK.

In the practice of docking and shortening this part of sheep, with the intention of keeping them more clean and free from dirt and disease, it is usually done so as to leave a few joints of the tail remaining, as the length of four or five inches, or more. It is common to cut off the tails of all the lambs at the time of castrating the male ones, in some places; but in others they perform it at different other suitable times. It should, however, always be done while the animals are young. The bleeding which succeeds this operation is supposed by some to be also very beneficial to the sheep.

TAIL-LOCKS, the locks of wool which are cut off from about the tails and the insides of the legs and thighs of sheep, in order to prevent dirt and nastiness attaching to and fixing upon them. They form a sort of wool, which is useful for inferior purposes. See WOOL.

It is always a good practice to keep sheep as clear as possible from these locks.

TAIL-ROT, a disease affecting cows that are ill fed during the winter. See YELLOW, *Joint*.

TAIL-Soaked, a disease incident to cows, by which the joint of the tail near the rump is affected.

TAIL of the Trenches, in the *Military Art*. See TRENCH.

TAIL, in *Sea Language*, is a name given by sailors to the extremities of a hurricane, in which the violence is considerably exhausted.

TAIL-Block, in a *Ship*, a small single block, having a short

short piece of rope attached to it, by which it may be fastened to any object at pleasure, either for convenience, or to increase the force applied to the said object. Falconer.

TAIL of a Lock, in *Inland Navigation*, the lower end, or entrance into the lower pond.

TAIL of a Seed, in *Botany and Vegetable Physiology*, is a generally downy or feathery appendage to some seeds, formed of the permanent elongated style. Examples are found in *Clematis*, *Anemone*, *Dryas*, and *Geum*. The use of such an appendage is either to serve as a wing, for the purpose of conveying the seed through the air; or to attach it to the coats of animals, by which the same end is answered, of transporting it to a distance from its original station.

TAIL-Piece of a violin, tenor, or base, is generally a piece of ebony attached to the end of the instrument, to which the strings are fastened below the bridge.

Tail-piece, or addition to a musical composition, in Italian is termed *coda*; which see.

TAILE, in *Geography*, a river of Hindoostan, which runs into the Mahanada at Sonepour.

TAILINGS, in *Agriculture*, a term applied to the lighter parts of grain, which in clearing fall to the hinder parts of the heap, especially where the wind is had recourse to in the operation.

TAILLE', or **TAILLEE**, in *Heraldry*. See **TRANCHÉ**.

TAILLE, Fr., in *Music*, implies the tenor part, vocal and instrumental. In vocal music it unites the base with the counter-tenor; in instrumental compositions it unites the base with the second violin. See **TENOR** and **COMPASS of Voices**, **VIOLA**, and **ALTO Viola**.

TAILLEBOURG, in *Geography*, a town of France, in the department of the Lower Charente; 6 miles N. of Saintes.

TAILLOIR, in *Architecture*, a term which some of our writers, after the French, use for abacus.

TAILOOR, in *Geography*, a town of Hindoostan, in Mysore; 10 miles N.N.W. of Vencatighery.

TAIM, a town of Brazil, on the E. coast of lake Merim. S. lat. $32^{\circ} 32'$.

TAIMA. See **TINO**.

TAIMEN, in *Ichthyology*. See **SALMO**.

TAIMURSKAIA, in *Geography*, a gulf or bay of Russia, in the Frozen ocean, between Cape Sievero Vostochnoi and Cape Sievero Zapadnoi. N. lat. 75° to 77° . E. long. $94^{\circ} 10'$ to $98^{\circ} 10'$.

TAIN, a town of France, in the department of the Drome; 9 miles W.N.W. of Romans.

TAIN, or *Thane*, said to be derived from the Scandinavian *ting*, or court-day, a royal borough, and the county-town of Rosshire, Scotland, is situated on the southern shore of the Frith of Dornoch; 201 miles N. by W. from Edinburgh. The town is old and irregularly built; but a number of new houses have lately been erected. Several acres have also been recently built on, forming a suburb, which is separated from the town by a small river, over which is a bridge. The parish church, which was built in 1471, was formerly collegiate. Tain is a chartered royal borough, and unites with Dingwall, Dornoch, Kirkwall, and Wick, in sending a representative to parliament. A well-supplied market is held weekly, and six fairs annually.

The parish of Tain extends about eight miles in length, and two in breadth. Its surface is in general flat, except towards the west, where it rises into small hills. The only manufactures carried on are the spinning of flax, and the tanning of leather. Here is a parochial school, which is ably conducted, and is in a flourishing condition: besides which, there is a society's school in the eastern district.

The population of the borough and parish, according to the return to parliament in the year 1811, was estimated at 2384; the number of houses 526.—Carlisle's Topographical Dictionary of Scotland, vol. ii. Beauties of Scotland, vol. v.

TAINACH, a river of Wurtemberg, which runs into the Nagold, 2 miles S. of Calw.

TAI-NGHAN, a city of China, of the second rank, in Chan-tong; 255 miles S.S.E. of Peking. N. lat. $36^{\circ} 15'$. E. long. $116^{\circ} 50'$.

TAINHA, in *Ichthyology*, a name given by some to a species of mullet caught in the American seas, and more usually called the *curema*.

TAINT, in *Law*, signifies either, substantively, a conviction, or, adjectively, a person convicted of felony, treason, &c. See **ATTAINT**.

TAINY, in *Geography*, a town of Hindoostan, in Dindigul; 4 miles N. of Outampaleam.

TAJO. See **TAGUS**.

TAI-OUAN, a city and sea-port, situated on the west coast of the island of Formosa, and the capital of the island. The streets, which are drawn nearly in a line, almost a league long, and from 30 to 40 feet broad, abound with shops of silk, china-ware, and other commodities, in which the Chinese excel. The houses are mostly covered with clay and bamboo. The town is neither walled nor fortified. The harbour is sheltered from every wind, but its entrance is difficult, on account of the increasing accumulation of sand. N. lat. 23° . E. long. 113° .

TAIPARA, or **TUIPARA**, in *Ornithology*, the name of a Brazilian species of parouquet. It is of the size of a lark, and of a pale green colour over its whole body; its tail is short, not reaching beyond the tips of the wings when closed; its beak is red, and its legs are grey; near the origin of the beak it has a semi-lunar red spot on the head, and a yellow spot on the middle of each wing. It builds in the deserted abodes of ants on trees. Marcgrave's Hist. Bras. See **PSITTACUS**.

TAI-PING, in *Geography*, a city of China, of the first rank, in Kiang-nan, on the Yang-tse river; 525 miles S. of Peking. N. lat. $31^{\circ} 38'$. E. long. $118^{\circ} 14'$.—Also, a city of China, of the first rank, in Quang-li; it is built on a point of land, almost surrounded by a river; fortified on the land side by a wall. Its territory is very fruitful, well cultivated, and populous. It has a number of forts, on account of its vicinity to the kingdom of Tonquin; 1175 miles S.S.W. of Peking. N. lat. $22^{\circ} 25'$. E. long. $106^{\circ} 34'$.

TAI-SANG, a town of Corea; 17 miles S.S.E. of Hoang-tcheou.

TAISERO, a town of Japan, in the island of Ximo; 75 miles N. of Nangafaki. N. lat. $33^{\circ} 30'$. E. long. $132^{\circ} 7'$.

TAISUGAN KARAKOL, a lake of Russia, in the government of Upha; 132 miles S.S.W. of Orenburg. N. lat. $54^{\circ} 32'$. E. long. $53^{\circ} 44'$.

TAI-TCHEOU, a city of China, of the first rank, in Tche-kiang. This city, which has six others in its district, is situated on the bank of a river, in a very mountainous country. The neighbourhood of the sea supplies it with all things necessary. The most remarkable thing is, that they can catch a kind of thornback, whose skin is proper for several uses, especially to make scabbards for cutlasses, of which they carry on a great trade in the country, and transport them into Japan, and throughout the empire; 722 miles S.S.E. of Peking. N. lat. $28^{\circ} 55'$. E. long. $121^{\circ} 2'$.

TAITI. See **OTAHETE**.

TAI-TING, a city of China, of the second rank, in Koci-

Koei-tcheou; 967 miles S.S.W. of Peking. N. lat. $27^{\circ} 5'$. E. long. $105^{\circ} 14'$.

TAI-TONG, a city of China, of the first rank, in Chan-fi. It is situated in a mountainous country, and is the only place exposed to the incursions of the Tartars: it is very well fortified, according to the manner of the Chinese, and has a very strong garrison; its territory is surrounded by the great wall, which has forts from place to place; its jurisdiction is very large, and extended over four great cities of the second order, and seven of the third: its mountains abound with all kinds of simple and medicinal herbs, which the botanists gather with great care. Lapis lazuli is in great plenty here; and there is a kind of jasper, which is transparent, and as white as agate: porphyry, marble, and jasper of all colours are very plentiful; and here is also a great trade for skins; 155 miles W. of Peking. N. lat. $40^{\circ} 5'$. E. long. $112^{\circ} 44'$.

TAITOU SAHA, a small island in the sea of Japan. N. lat. $42^{\circ} 32'$. E. long. $130^{\circ} 42'$.

TAI-TSANG, a city of China, of the second rank, in Kiang-nan; 567 miles S.S.E. of Peking. N. lat. $31^{\circ} 30'$. E. long. $120^{\circ} 24'$.

TAIVERAM, a town of Hindoostan, in the province of Dindigul; 8 miles N.W. of Outampaleam.

TAJUNA, a river of Spain, which rises in the north part of New Castile, and runs into the Xarama, a little before its union with the Tagus.

TAIWAN. See FORMOSA.

TAI-Y, a city of China, of the second rank, in Quang-fi, on the fourth side of the Pofoi; 1125 miles S.S.W. of Peking. N. lat. $23^{\circ} 24'$. E. long. $106^{\circ} 18'$.

TAI-YUEN, a city of China, of the first rank, in Chan-fi; 230 miles W.S.W. of Peking. N. lat. $37^{\circ} 54'$. E. long. $111^{\circ} 56'$.

TAIZALUM, in *Ancient Geography*, a promontory of the isle of Albion, between the mouth of the Celnus and that of the Diva. (Ptol.) This is supposed to be Kynaird-Head, near Fraserburgh, in Buchan; the Celnus being the river Spay, in the shire of Elgin, and the Diva the river Dee at Aberdeen.

TAK, EL, in *Geography*, a town of Persia, in the province of Segestan; 15 miles N. of Zareng.

TAKA, a town of Nubia, capital of a district, called Takaki, on the Belese; 50 miles S.E. of Ilak.

TAKAGUS, a town of Japan, in the island of Nippon; 60 miles N.W. of Meaco.

TAKAKAKKAN, a small island in the Eastern Indian sea, near the east coast of Borneo. N. lat. $3^{\circ} 8'$. E. long. $116^{\circ} 51'$.

TAKALUOTO, a small island on the E. side of the gulf of Bothnia. N. lat. $61^{\circ} 39'$. E. long. $21^{\circ} 10'$.

TAKAMIDJA, a town of Japan, in the island of Nippon; 150 miles S.W. of Meaco.

TAKAUL, a town of Asiatic Turkey, in Caramania; 40 miles N. of Cogni.

TAKE and Leave, in *Sea Language*. The sailors say, a ship can take and leave upon her when she will; when she fails so well, that she can come up with another, or outfail her at pleasure.

TAKE, Thistle. See THISTLE.

TAKE-In, To, in *Ship-Building*, is to come-up a sett and make it fall again closer to the plank, as it works nearer to the timbers.

TAKE-In Sail, To, is to diminish its surface by reefing, &c. particularly when the wind increases too much. See **TAKING-IN**.

TAKENO, in *Geography*, a town of Japan, in the island of Ximo; 40 miles E.S.E. of Ikva.

TAKERS—Carr-Takers. See **CARR-TAKERS**.

TA-KIA-TCHE, in *Geography*, a town of China, on the W. coast of the island of Formosa. N. lat. $24^{\circ} 22'$. E. long. 119° .

TAKING-IN, in *Sea Language*, denotes the act of brailing-up and furling the sails at sea, particularly when the wind increases. It is generally used in opposition to *setting*.

TA-KIRON-HOTUN, in *Geography*, a town of the kingdom of Corea; 425 miles E. of Peking.

TAKLACOT, a town of Thibet; 60 miles N.E. of Kerion.

TAKMITZSKAIA, a town of Russia, in the government of Tobolsk, on the Irtych; 36 miles S. of Tara.

TAKPO, a large province of Thibet, which is subdivided into seven takpos. On the N. it has the province of U, on the S. Combo, on the E. Cobang, and on the W. Tzhang.

TAKTANG, a river of Russia, which runs into the Lis, N. lat. $62^{\circ} 24'$. E. long. $89^{\circ} 44'$.

TAKY, a town of Bengal; 30 miles E. of Calcutta.

TAL, a name used by some writers on the materia medica to express the dung of peacocks; and by some of the chemical writers for any alkali salt.

TALA, in *Botany*, a name by which some authors call the plant, whose seed is the sesamum, or oily purging grain of the shops.

TALABON, in *Geography*, a town on the W. coast of the island of Gilolo. N. lat. $1^{\circ} 40'$. E. long. $127^{\circ} 20'$.

TALABONG, in *Ornithology*, a name given by the inhabitants of the Philippine islands to a species of heron, common among them; which is much smaller than our heron, and perfectly white all over.

TALABRIGA, in *Ancient Geography*, a town of Spain, in Lusitania, towards the south, upon the Vatna, not far from the sea, S.W. of Langobriga.

TALABROCA, the name of one of the most celebrated towns of Hyrcania. Strabo.

TALACACHA, in *Geography*, a town of South America, in the province of Tucuman; 15 miles S. of St. Miguel de Tucuman.

TALACOUAN, a town of Lower Siam, on an island in the Mecon; 30 miles S. of Juthia.

TALÆDITES, *ταλαειδης*, in *Antiquity*, gymnical exercises in honour of Jupiter *Ταλαιος*.

TALAFa, in *Geography*, a small island in the South Pacific ocean, among those called Hapaae, S.W. of Ho-laiva.

TALAGIR, a small island among the Philippines; 25 miles W. of Samar.

TALAGOS, a town of Africa, in the country of Sierra Leone. N. lat. $10^{\circ} 20'$. W. long. $13^{\circ} 40'$.

TALAGUADA, a town of South America, in the province of Carthagea; 10 miles N.N.W. of Mompox.

TALAHSECHTE, an Indian town of East Florida, on the river St. Juan, near the bay of Apalache, in the gulf of Mexico; 52 miles N. of St. Mark. This town contains about 30 habitations, constructed of frame-work; and covered with the bark of the cypress-tree. The inhabitants form large handsome canoes of the trunks of cypress-trees, capable of holding 20 or 30 warriors. In these they descend the river on trading or hunting expeditions on the sea-coast, islands, and keys as far as the point of Florida; and sometimes they cross the gulf and sail to the Bahama islands, and even to Cuba, returning with cargoes of spirituous liquors, coffee, sugar, and tobacco.

TALAI-

TALAI-HAI, a town of Chinese Tartary. N. lat. $44^{\circ} 17'$. E. long. $120^{\circ} 45'$.

TALAI-HOTOC, a town of Thibet; 105 miles S.W. of Haratoubé.

TALALALUM, or THALATATUM, in *Ancient Geography*, a town of Africa Propria, on the route from Tacapæ to the Greater Leptis.

TALAMANCA, in *Geography*, a town of Spain, in New Castile; 14 miles N.W. of Guadalaxara.

TALAMATA, a town of Hindoostan, in Coimbatore; 15 miles N. of Damicotta.

TALAN, a small island in the sea of Ochotsk. N. lat. $59^{\circ} 30'$. E. long. $149^{\circ} 14'$.

TALANGBOANG, a town on the W. coast of Sumatra. S. lat. $4^{\circ} 21'$. E. long. $105^{\circ} 44'$.

TALANT, a town of France, in the department of the Côte d'Or; 2 miles N.W. of Dijon.

TALANTA, a town of European Turkey, in the island of Negroponte; 34 miles N.W. of Negroponte.—Also, a town of European Turkey, in Livadia; 18 miles N.E. of Livadia.

TALA-OSO, a town of Chinese Tartary, in the country of Hami; 28 miles E.S.E. of Hatamtam.

TALAPOINS, a name given in Siam to those who dedicate themselves to religion. See SIAM.

TALAPOOSEE, in *Geography*, the great N.E. branch of the Alabama or Mobile river, in Florida. It rises in the high lands near the Cherokees, and runs through the high country of the Oakfuskee tribes, in a westerly direction, being full of rocks, falls, and shoals, till it reaches the Tackabatches, where it becomes deep and quiet; from thence the course is W. about 30 miles to Little Talafsee, where it is united with the Coofa or Coofa Hatcha. The lower part of this river is, in most maps, called Oakfuskee.

TALAPORUM, a town of Hindoostan, in Calicut; 20 miles N.N.W. of Tellicherry.

TALARHO-KARA-PALHASSUM, a town of Chinese Tartary, in the country of the Eluths; 715 miles N.W. of Peking. N. lat. $47^{\circ} 34'$. E. long. $102^{\circ} 34'$.

TALARIUS LUDUS, among the Romans, a game somewhat resembling our dice-playing, and performed with a kind of gold or ivory dice, which they shook as we do in a box, before they threw them. There was this difference, however, between their game and ours, that our dice have six sides, because they are cubical; but theirs had but four, and were conically shaped. They made use of them for divination, as well as playing; and they concluded upon a good or evil augury, according to what came up. As they usually threw four of them at a time, the best chance was when four different sides came up. The sides were called by the name of some animal, as the dog, vulture, basilisk, &c.: or of some deity, as Venus, Hercules, &c. Some authors have been of opinion, that they were marked with the forms of animals, or images of gods, and not with numbers or dots, as our dice are.

TALARN, in *Geography*, a town of Spain, in Catalonia; 22 miles N. of Balaguer.

TALASSEE, or TALLASSEE, a county consisting of a tract of land bounded by East Florida on the S., N. by Alatomaha river, E. by Glynn and Camden counties, and W. by a line extending from the W. part of Ekanfanoka swamp, in a N.E. direction till it strikes the Alatomaha river, at the mouth of the Oakmulgee.—Also, a town of the Upper Creeks, in the Mississippi territory, on the S. side of Talapoosee river; called also Big Talafsee.

TALASSIO, among the Romans, an acclamation used at marriages.

TALATUM, in *Ancient Geography*, the name of a temple of the sun, erected in Laconia, on the summit of mount Taygetus.

TALAVAN, in *Geography*, a town of Spain, in Estremadura; 25 miles S. of Plasencia.

TALAVERA *la Real*, a town of Spain, in Estremadura; 13 miles S.E. of Badajos.

TALAVERA *la Reyna*, a town of Spain, in New Castile, on the Tagus, situated in a valley, and fortified; famous for its earthen-ware; 35 miles W. of Toledo.

TALAVERA *la Vieja*, a town of Spain, in New Castile; 6 miles W.S.W. of Toledo.

TALAUVERUELA, or *Talavera de Badajos*, a town of Spain, in Estremadura, on the Guadiana; 9 miles E. of Badajos.

TALAUMA, in *Botany*, a word probably of South American origin, applied in the herbarium of Surian, now possessed by Jussieu, to the plant on which Plumier originally founded his genus MAGNOLIA. See under that article, sp. 2, our reasons for not receiving *Talauma*, for the present at least, as a distinct genus.

TALBERT'S ISLAND, in *Geography*, a small island in the Atlantic, on the coast of Georgia, the N. point of which is in N. lat. about $30^{\circ} 44'$, where St. Mary's river discharges itself into the ocean, between this island and Amelia island on the N. N. lat. $30^{\circ} 36'$. W. long. $81^{\circ} 42'$.

TALBOT, an island on the coast of East Florida, eight miles long and two wide.—Also, a county of Maryland, on the E. coast of Chesapeake bay, bounded E. by Choptank river, which divides it from Carolina county, and S. by the same river, which separates it from Dorchester. The soil of this county is rich and fertile; and it contains 14,230 inhabitants.

TALBOT, in *Zoology*, a sort of dog, noted for its quick scent, finding out the tracks, lodgings, and forms of beasts, and pursuing them with open mouth and continual cry, with such eagerness, that if not taken off by the huntsman, he is often spoiled.

TALC, in *Mineralogy*, *Idem*, Haüy. The name talc, in the present systematic arrangement of Werner, is placed both as the head of a genus and a family. Brongniart restricts the name to those minerals which possess the following characters: they are soft and unctuous to the touch, and leave upon the nail, or on the surface of cloth on which they are rubbed, a white mark, which has sometimes a nacreous lustre. The texture of talc is lamellar, or fibrous: the laminae are flexible but not elastic. Talc has always a shining lustre, and is sometimes splendid and nacreous; it is translucent and often transparent; it yields easily to the nail. The laminae of which it is composed, open a little by the action of fire or of the blowpipe; the fragment swells, and the extremities of the laminae are with difficulty fusible into a white enamel. These characters, which are easily recognised, serve to distinguish talc from chlorite and nacrite, which are very fusible; and from steatite, serpentine, or the unctuous clays, which are compact, have an earthy or scaly fracture, and but little unctuousity. Talc has another remarkable property; it acquires positive electricity when rubbed with resin. Talc is susceptible of crystallization, and forms hexagonal laminae. The primitive form of the crystal is a right rhomboidal prism, in which the angles at the base are 120° and 60° . Its specific gravity varies from 2.58 to 2.87. The prevailing colours are white, apple-green, and yellow.

Talc

TALC.

Talc is divided by some mineralogists into three sub-species, viz. common talc, indurated talc, and columnar talc.

Common talc; talc laminaire, Haüy. Its colours are those before enumerated, but the green sometimes passes into dark blue. The laminae are very tender and flexible, but not elastic: by this they may be distinguished from the laminae of mica, which possess a considerable degree of elasticity. In France this talc is called *craie de Briançon*; it is found in considerable masses in rocks of serpentine, accompanied with actinolite, granular lime-stone, and dolomite, along with indurated talc. The constituent parts are as follow:

	Vauquelin.	Klaproth.
Silex - - - -	62	61.75
Magnesia - - -	27	30.50
Alumine - - -	1.50	
Potash - - - -		2.75
Oxyd of iron - -	3.50	2.50
Water - - - -	6	2.25

It is found in Aberdeenshire and Bamfshire, in Scotland, and in various parts of the continent of Europe, where rocks of serpentine and porphyry occur. The talc which is brought from the mountains of the Tyrol is called in commerce *Venetian talc*.

Talc enters largely into the composition of the cosmetic named *rouge*. This substance is prepared by rubbing together in a warm mortar, generally of serpentine, certain proportions of carmine and finely powdered talc, with a small portion of oil of benzoin. The Romans prepared a beautiful blue or purple colour, by combining this substance with the colouring fluid of the buccinum reticulatum and buccinum lapillus, testaceous animals abounding on the coasts of the Mediterranean. The flesh-coloured polish on figures made of gypsum is given by rubbing them with talc. The Persians, according to Tavernier, whiten the walls of their houses by means of lime-water, and then powder them with silver-coloured talc. Talc has sometimes been used medicinally by the Chinese and Europeans.

The chief use of the Russian is as a screen or cover for paintings in miniature and crayons; to which purpose thin slices of it are used. The Venetian is sometimes also used for a focus; in order to which, by reason of the difficulty of pulverizing it, &c. they content themselves to rasp it with the skin of a sea-dog, and to pass the raspings through a sieve.

Pliny, in his Natural History, lib. xxxvi. c. 22. observes, that the Romans not only used the Russian sort for window-lights, but they also paved the circus with a kind of it. See GLASS.

Indurated talc is less flexible and less translucent than the preceding: it occurs in masses, and has sometimes a radiated structure; its colours are various shades of green and greenish-grey. It forms beds of considerable size in mountains of gneiss, mica-slate, and serpentine; it approaches nearly to pot-stone, and even to steatite, in many of its characters. It occurs in Perthshire and Bamfshire, in Scotland, and in France, Sweden, Saxony, Siberia, the Tyrol, and Switzerland. It is employed for drawing lines by carpenters, taylors, hat-makers, and glaziers. It is sometimes made into culinary vessels, like pot-stone, and is employed in powder for removing stains of grease from silk.

Columnar talc occurs in thin columnar prismatic concretions, and it is opaque. The connection between talc, stibectus, pot-stone, serpentine, chlorite, and even mica, may

be traced by their apparent graduation into each other, particularly in some of the rock formations. See ASBESTUS, POT-STONE, &c.

The mixture of talc with different kinds and quantities of glass may be successfully performed with a violent fire, but not with a smaller degree: thus three parts of talc, with one part of crystalline glass, make only a spongy and friable mass in a common fire; but in a more violent one, they become a firm and solid mass of a brown colour. Minium, or glass of lead, mixed in equal quantities with talc, and set in a violent fire, runs into a yellowish glass, resembling the opaque pieces of amber; and two parts of minium to one of talc, produce a clear and transparent yellow glass, which is of a hardness capable of giving fire with steel. The alkaline earths, mixed with talc, produce a mass scarcely vitrifiable by any fire: hence appears the reason why copels made of lime and talc are so very hard to vitrify. Minium, added to these mixtures, make them combine into a firm mass, but without perfect fusion; but borax added to them, melts them readily into a true glass. The gypseous earths mixed with talc, will not unite into a mass in any degree of fire; but if borax be added, the talc readily melts. Thus two parts of talc, two parts of that spar or gypseous matter called *glacies Mariae*, or the common plated spar, with one part of borax, run into a yellow mass resembling a topaz.

The argillaceous earths do not vitrify with talc; but they run into a mass of great hardness, which will give fire with steel, and is very serviceable to make crucibles of, these vessels not suffering the glass of lead to run through them. Talc, joined with the vitrifiable stones, forms no remarkable body, but the mass remains friable; but from these masses, by the addition of proper matter to render them fluid, great variety of elegant compounds may be made. Thus if talc be mixed in equal quantities with powder of flints, on adding to the whole a fourth part of crystal-glass, the whole unites into an opaque but solid white mass. Alkali-salt, added in equal quantity to talc and flint, gives a transparent yellow glass; and white sand, talc, and a fixed alkali, in equal quantities, afford a green glass; with other mixtures of this kind, in different quantities, the resemblances of many beautiful stones are produced; and what is very remarkable, some grains of metalline matter are often found on the surface of the masses.

Cæsalpinus, Aldrovand, and some others affirm, that talc melted with copper, or added to copper, while in fusion, gave it a white colour: this being taken for granted, authors have hence agreed that talc contains an arsenical earth. But experiment shews this to have been a false assertion, in regard to talc; and probably it only owes its origin to the cant language of some of the alchemists, who have called the flowers of zinc talc, though these alone must render copper yellow, not white. Antimony and talc, first calcined with nitre, run in a violent fire into a sort of flint, which will give fire with steel. With regulus of antimony and the black flux, it runs into a black mass; and with bisnuth it calcines into a grey powder. So little is there in the proposals of the chemists for the metallization of talc by antimony and bisnuth. Mem. de l'Acad. de Berlin, Ann. 1746.

In what part of Mr. Boyle's works the learned author, from whom the foregoing extract was taken, has found that talc may be reduced by common fire to a gypsum in an hour, we know not; but we find that Mr. Boyle says, that the calcination of talc is so very difficult, that eminent chemists have looked upon calxes of talc as counterfeits. Works abr. vol. i. p. 160.

Mr. Boyle mentions the extracting of gold from talc, as having

having sometimes succeeded. See Works abr. vol. i. p. 160. but *vide supra*.

TALC, *Philosophic*, a name given by some of the chemical writers to the flowers of zinc.

This substance, dissolved in vinegar, affords what they have in their unintelligible language called *oil of talc*, and extolled as a thing of vast power in the fixing of mercury, and many other imaginary operations; and besides this, they call it a sovereign remedy for all diseases.

TALCAGUANO, or TALCAGUANA, in *Geography*, a sea-port of Chili, nine miles within the point of the same name, and about six from the town of Conception. This is the principal port in the bay of Conception, and is much the most frequented, as ships that anchor here have not only better ground than in any other part of the bay, but are in some measure sheltered from the north winds. The town, or village, as Perouse calls it, has been built since the city of Conception was destroyed by an earthquake in 1751: it stands on the river Biobin, and is said to contain 10,000 inhabitants. Here are the episcopal cathedral, the seat of the bishop, and all the religious houses. The government of the adjacent district has been wholly military and ecclesiastical. The country round it is very healthy and fertile. Great numbers of cattle are annually killed for their hides and tallow, which are sent to Lima. About 200,000 dollars' worth of gold is annually collected from the sands in the rivers of this bishopric. The Indians of the country have numerous herds of cattle, and plenty of horses, and live more like the Tartars of Asia than the savages of North America. Ships are here supplied with water, wood, and other necessaries. N. lat. $36^{\circ} 42'$. E. long. $73^{\circ} 6'$.

TALCAGUANO *Point*, a cape on the coast of Chili, 11 leagues N.E. of the island of Santa Maria, and 2 N. of Port St. Vincent.

TALCAN, a town of Asia, in Tokaristan, besieged by Gengis Khan in the year 1221, and taken after a siege of seven months; 100 miles S.E. of Termed. N. lat. $36^{\circ} 45'$. E. long. $67^{\circ} 9'$.

TALCKENSTEIN, a mountain of Silesia; 4 miles N.N.E. of Loewenberg.

TALCONAH, a town of Bengal; 30 miles E. of Goragot.

TALCOT, a town of Hindoostan, in Concan; 25 miles N.E. of Goa.

TALCOTE, a town of the island of Ceylon; 20 miles W.S.W. of Candy.

TALCOUS SLATE, in *Geology*, is considered by some geologists as a variety of clay-slate, but it has a nearer resemblance to mica-slate. The colour is generally a greenish-grey, with a shining lustre, like that of the finer kinds of mica-slate. It is softer than mica-slate, but is frequently divided into laminae by thin seams of quartz, and has a twisted or contorted form. The slate on some of the mountains of the higher Alps, as described by Saussure, seems to be of an intermediate kind between mica-slate and talcous slate. Talcous slate occurs on the western side of the island of Anglesea, and in many alpine districts, forming beds in clay-slate. See SLATE.

TALDINGA, in *Geography*, a town of Bengal; 15 miles W. of Bissunpour.

TALE, in *Law*. See COUNT and DECLARATION.

TALE, or PAEL, in *Commerce*, a weight for gold and silver in China, and certain parts of the East Indies; and also a money of account. In China, each tale is 10 maces = 100 candareens = 1000 cash. A tale of fine silver should be worth 1000 cash, which cash is composed of six parts of

VOL. XXXV.

copper, and four of lead, having a square hole in the middle, so that they may be strung on a string or wire; but on account of their convenience for common use, their price is sometimes so much raised, that only 750 cash are given for the tale.

Gold is not considered as money, but as merchandize; and it is sold in ingots of a determinate weight, called by the English "shoes" of gold; the largest of which weighs 10 tales, and the gold is reckoned 94 touch (*i. e.* 94 parts fine in 100), though it is only 92 or 93. Of late, from 100 to 110 tales of silver of 94 touch, have been given for 10 tales of gold of 92 or 93 touch; and sometimes from 110 to 120 tales, or even more, of Spanish dollars, reckoned at 92 touch, have been paid for 10 tales of gold. When gold is exchanged for silver, its price is always valued by the tental weight, and it is sold either above or below touch, as follows: *viz.* if the gold be 96 touch, and sold at 5 under touch, subtract 5 from 96, and 91 remains: then 91 tales of silver are paid for 10 of gold: if gold be sold at 10 above touch, the fineness being still 96, add 10 to 96, and 106 tales of silver are paid for 10 tales of gold. Silver ingots are used as money, and are from $\frac{1}{2}$ to 100 tales, their value being determined by their weight. In payment of small sums, they sometimes lay the ingot on the fire, and by striking it with a hammer, detach smaller pieces from it. The English reckon the tale of silver at 6s. 8d. sterling, so that 1l. sterling is = 3 tales. The catty of 16 tales weighs 19 oz. 6 dwts. 4 grs. English troy; so that 10 tales would weigh 5792 English grains. Upon the whole, the weight of a Chinese tale may be taken at about 580 grains English troy; and therefore 48 tales = 58 ounces troy weight. One hundred Spanish dollars weigh about 722 tales. The heaviest weight for merchandize (peculiar to the coast of Canton) is called pecul, and contains 100 catties or 1600 tales, with the same decimal division as above. Hence a pecul = 132 lbs. 8 oz. 9 dr. avoirdupois: and a catty = 21 oz. $3\frac{1}{2}$ dr. avoirdupois.

At Acheen, in the isle of Sumatra, accounts are kept in tales, pardows, mace, copangs, and cashes. A tale = 4 pardows = 16 mace = 64 copangs. The coins of the country are mace and cashes. The mace is a small gold coin weighing nine grains, and worth about 14d. sterling. The cashes are small pieces of tin or lead, 2500 of which usually pass for a mace, subject to occasional variation. In Siam, accounts are kept in catties, tales, ticals or tuals, miams, fanangs, and cowries. The catty is 20 tales: the tale = 4 ticals = 16 miams = 32 fanangs: the fanang is = 800 cowries. In Tonquin, accounts are kept in tales of 10 mace or 100 candareens. The tale weighs here 1 oz. 4 dwts. $14\frac{1}{2}$ grs. English, which is about 10 grs. more than the Chinese tale. Kelly's Cambist.

TALED, in the *Jewish Antiquities*, a sort of habit that the Jews wore, chiefly when they repeated their prayers in the synagogue. Numbers, xv. 38. Deuteronomy, xxii. 12.

It served instead of that square garment they wore heretofore, to which Moses had appointed that they should fasten borders of blue to the four quarters, and fringes or ribbands all along the borders. But at present, that they may not be exposed to the laughter of the people for the too great singularity of their dress, they content themselves with wearing a square piece of cloth underneath, with four tufts at the four corners, and when they meet in the synagogue to say their prayers, they cover their heads with a square woollen veil, which has four tufts at its four corners. It is this they call *shaled*, or *taled*. Calmet, Dict. & Leo of Modena, Ceremonies of the Jews, p. i. ch. 11.

G

TALEGONG,

TALEGONG, in *Geography*, a town of Hindoostan, in Dowlatabad; 15 miles S. of Oudighir.—Also, a town of Baglana; 12 miles S. of Chandor.

TALEKAN, a town and castle of Persia, in the province of Khorassan; 160 miles N.E. of Herat.—Also, a town of Persia, in the province of Irak; 30 miles N.E. of Hamadan.

TALENNI, a town of Japan, in the island of Nippon; 160 miles W.N.W. of Meaco.

TALENT, **TALENTUM**, a weight, and a coin, both very famous among the ancients; but very different in different countries.

The value of the talent it is very hard to assign in English money, as being used among all the people throughout the East, and its value, and the manner of computation, being different among each: a difficulty abundantly shewn by Budæus, in his learned treatise "De Asse."

There were various kinds of talents, both with regard to weight and to species; the value of these last still increasing, as the metal of which they consisted was purer, though the talent weights contained the same number of pounds and drachms. Accordingly, all talent weights are equally sixty minæ, and the mina one hundred drachmæ; but the drachma of one place exceeding that of another, there hence arose a difference in the talents.

The common Attic talent then (the talent weight we mean) contained sixty Attic minæ, or six thousand Attic drachmæ; equal, according to Dr. Arbuthnot's reduction, to fifty-six pounds, eleven ounces, seventeen and one-seventh grains, English troy weight.

There was another Attic talent, by some said to consist of eighty, by others of one hundred minæ. The Egyptian talent was eighty minæ; the Antiochian also eighty; the Ptolemaic of Cleopatra eighty-six and two-thirds; that of Alexandria ninety-six; the Insular talent one hundred and twenty; and that of Antioch three hundred and sixty minæ. In the valuation of money, the Grecian talent, according to Dr. Arbuthnot, was equal to sixty minæ, or reckoning the mina at *3l. 4s. 7d.* equal to *193l. 15s.*; the Syrian talent in this valuation consisted of fifteen Attic minæ; the Ptolemaic of twenty; the Antiochian of sixty; the Euboic of sixty; the Babylonian of seventy; the greater Attic of eighty; the Tyrian of eighty; the Egeian of one hundred; the Rhodian of one hundred; and the Egyptian of eighty minæ. (See Arbuthnot's *Tables of Ancient Coins*, &c. p. 33, and Tab. 18, 19, 23, 24.) Stating the Attic drachm of silver at nine-pence of our money, the best medium value, the mina of Athens will be worth *3l. 15s.*; and the Athenian common talent, *225l.*; and the rest may easily be estimated in proportion.

But Mr. Raper makes the Attic talent, which consisted of sixty minæ, or six thousand drachmæ, each drachm being equal to sixty-six grains and a half troy weight, or *3l. 17s. 4d.* sterling, equal to *232l. 3s.* See **DRACHM**.

This ingenious writer also observes, that historians and others mention the Egeian and the Euboic talent. The former weighed ten thousand Attic drachms; but, like other talents, contained only six thousand of its own; which being so much heavier than the Attic, the Athenians called it *ταχυον δραχμιον*, or the thick drachm. This talent was used at Corinth; and in a passage of Aulus Gellius, lib. i. c. 8. it is valued at ten thousand Attic drachms; and was probably used in most of the cities of Peloponnesus. If the Attic drachm weighed sixty-six and a half troy grains, the Egeian should weigh one hundred and ten and five-sixths, which Mr. Raper states at one hundred and eleven. This

Egeian talent he concludes from the mean drachm of six Macedonian coins, which he found to be one hundred and eleven grains and one-fourth, must have been the standard of the Macedonian money, till Philip changed it. And it appears likewise to have been the standard of the Ptolemaic money in Egypt. Pliny indeed (*Nat. Hist. lib. xxxiii. c. 3.*) tells us, on the authority of Varro, that the Egyptian talent weighed eighty Roman pounds; but he supposes that this is a false reading, and that for Ægyptium we should read Euboicum: for Pliny is speaking of the riches of Asia, where the Euboic talent was used for weighing gold; and it is known, that the weight of that talent was settled at eighty Roman pounds, by the treaty between the Romans and Antiochus. There is a passage in Pollux (*lib. ix. c. 6. § 86.*) which makes the Egyptian talent contain fifteen hundred Attic drachms. But this, he apprehends, is an injudicious interpolation in the last collection of that author.

The Euboic talent, says this writer, certainly came from Asia; for Herodotus (*lib. iii. sect. 89.*) tells us, the kings of Persia weighed their gold by that talent: in the same place he informs us, that the Babylonian talent weighed seventy Euboic minæ. Pollux says, it weighed seventy Attic minæ. Therefore the Euboic talent should be equal to the Attic. But Ælian (*Var. Hist. lib. i. c. 22.*) tells us, that it weighed seventy-two Attic minæ; and if so, the Euboic talent should be heavier than the Attic, in the proportion of seventy-two to seventy. By two passages, cited by Mr. Raper, from Xenophon, *Exped. lib. i.* it appears probable, that the Babylonian talent weighed above seventy Attic minæ, and above seventy Euboic minæ; and if Pollux took his value of the Babylonian talent from Herodotus, as the text now stands, and Ælian his value of the same from a more correct copy of that author, or from some better authority, the Euboic talent must have been equal to the Attic. Accordingly it contained six thousand Attic drachms. *Phil. Transf. vol. lxi. part ii. p. 483, &c.*

There is another talent much more ancient, and much less than any of those already mentioned, which Dr. Arbuthnot calls the Homeric talent of gold, supposed, he says, to be equal to three Attic aurei. Pollux speaks of such a talent. Eustathius upon Homer reckons it worth twenty-four drachmæ. That its value was small, whether fixed or uncertain, is conjectured from the passage of Homer, where, describing the prizes at the funeral of Patroclus, two talents of gold are proposed as a more inconsiderable prize than a mare with foal, &c. Hence Mr. Raper, *ubi supra*, p. 527, concludes, that it was the same that the Dorian colonies carried to Sicily and Calabria: for Pollux tells us, from Aristotle, that the ancient talent of the Greeks in Sicily contained twenty-four nummi, each of which weighing an obolus and a half, the talent must have weighed six Attic drachms, or three darics; but the daric weighed very little more than one guinea; and if two talents weighed about six guineas, we may reckon the mare with foal worth twelve; which was no improbable price, since we learn from a passage in the *Clouds* of Aristophanes, that, in his time, a running horse cost twelve minæ, or above forty-six pounds sterling; therefore this seems to have been the ancient Greek talent, before the art of stamping money had introduced the greater talent from Asia and Egypt.

According to this ancient talent, says Dr. Arbuthnot, some reckon the treasure of king David, particularly that mentioned *1 Chron. xxii. 14.* which, according to the common reckoning, would amount in gold talents to the value of *547,500,000l.* and the silver to above *342,000,000l.*; or reckoning according to the decuple proportion of gold to silver,

silver, the two sums would be equal. As David reigned in Judea after the siege of Troy, it is not improbable that Homer and he might use the same numeral talent of gold.

It is suggested by Mr. Pinkerton (Essay on Medals, vol. i. p. 65.) that all the ancient coins of Asia, Africa, Greece, Magna Græcia, and Sicily, were reducible to three talents or standards. 1. That of Egina, used in most of the more ancient silver coinages; and as it would seem in even the later of Egypt, Carthage, Greece, &c. 2. The Attic, being the Asiatic gold standard; afterwards used by Phidon, king of Argos, in estimating gold, and called Euboic, from Eubœa, one of the quarters of the city of Argos. It was afterwards used in Athens, and the greater part of the world, as the standard both of gold and silver. 3. The Doric, or Sicilian talent, of 24 nummi, each worth an obolus and a half: whence the talent is estimated at six Attic drachms, or three darics. These weights continued to be the standard of money after it began to be distinguished by impression; nay, to the fall of Greece, and prevalence of the Roman empire.

Among the Romans there were two kinds of talents, the *little* and the *great* talent; the little was the common talent; and whenever they say simply *talentum*, they are to be understood of this: the *little* talent was sixty minæ or Roman pounds; the mina, or pound, estimated at one hundred drachmæ, or denarii: it was also estimated at twenty-four great sesterces, which amounted to sixty pounds.

The *great* talent exceeded the less by one-third part. Budæus computes, that the little talent of silver was worth 75*l.* sterling; and the greater 99*l.* 6*s.* 8*d.* sterling. The greater of gold was worth 1125*l.* sterling.

TALENT, as a *species*, or *money*, among the Hebrews, was sometimes used for a gold coin, the same with the *shekel* of gold, called also *stater*, and weighing only four drachms. The Hebrews reckoned by these talents as we do by pounds, &c. Thus a million of gold, or million of talents of gold, among them, was a million of shekels, or nummi; the nummus of gold being the same weight with the shekel, *viz.* four drachms.

But the Hebrew talent weight of silver, which they called *cicar*, was equivalent to that of three thousand shekels (Exod. xxxviii. 25. 28.) or one hundred and thirteen pounds, ten ounces, one pennyweight, ten grains and two-sevenths, English troy weight, according to Arbuthnot's computation.

It should be observed, however, that the talent was not every where the same. The Hebrew talent weighed more than that of the Greeks, and is said to have amounted to 341*l.* 10*s.* 4*d.* and $\frac{1}{2}$. The common Attic talent might be worth about 193*l.* 15*s.* which might probably have been used by the Jews in their commerce.

TALES, in *Law*, a supply or addition of men for those impannelled on a jury of inquest, and not appearing, or at their appearance challenged by either party as not indifferent.

In such case, the judge, upon motion, grants supply to be made by the sheriff of one or more tales, such as are present in court, equal in reputation to those impannelled. For this purpose, a writ of *decem tales*, *octo tales*, and the like, was used to be issued to the sheriff at common law; and must be still so done at the trial at bar, if the jurors make default; but at the assizes, or nisi prius, by virtue of the statute 35 Hen. VIII. c. 6. and other subsequent statutes, the judge is impowered, at the prayer of either party, to award a *tales de circumstantibus*, of persons present in court, to be joined to the other jurors to try the cause; who are liable, however, to the same challenges as the principal jurors. This is usually done till the legal number of twelve be com-

pleted. The *tales de circumstantibus* is in some measure rendered useless by the statute for regulating juries, 3 Geo. II. c. 25. See CHALLENGE and JURY.

TALGA, in *Geography*, a town of Hungary; 8 miles N. of Tokay.

TALGARTH, a small town in a hundred of the same name, and county of Brecon, South Wales, is situated on the banks of the river Llyfni, at one end of the Black Mountains, which stretch hence into Herefordshire: from its situation it derived its name; Talgarth meaning literally the front of the hill. The town is a borough by prescription, but without privilege, jurisdiction, or municipal officers. The parish church is a substantial edifice, but has no architectural elegance, nor is it enriched by any remarkable monuments, ancient or modern: it has a tower, which forms a conspicuous object from most parts of the surrounding country. The population of the parish, which, besides the borough, contains five hamlets, was in the year 1811 returned to parliament as 1124, the number of houses being 274. No less than eight annual fairs are held here.

In the Forest hamlet of the parish of Talgarth are some vestiges of Dinas-castle, which, at a remote period, was a fortress of importance, but has long since been demolished. In Leland's time, it was "ruinous almost to the hard ground." From his description, it must have been of considerable dimensions. It consisted of three wards "waulled about," and had three parks and a forest attached to it. From the same writer we learn, that the castle was destroyed by the natives, that it might not be occupied by the favourers of Owen Glendwr.—*Beauties of England and Wales*, vol. xviii. South Wales, by T. Rees, F.S.A. Carlisle's Topographical Dictionary of Wales.

TALGAUTPORAM, a town of Hindoostan, in Mysore; 6 miles S. of Bangalore.

TALGRISTAN, a town of Persia, in the province of Irak; 50 miles E. of Nehavend.

TALGUL, a town of Hindoostan, in Mysore; 10 miles S.S.W. of Sirpy.

TALHA-KIAMEN, a post of Chinese Tartary. N. lat. 46° 16'. E. long. 123° 44'.

TALHAM, a town of Austria; 2 miles S.S.W. of Voglbruck.

TALI, a town on the W. coast of the island of Formosa. N. lat. 23° 36'. E. long. 129° 41'.

TA-LI, a city of China, of the first rank, in Yun-nan. This is the principal place where they make curious tables, and other ornaments of fine marble, which is got from a mountain called *Tienfung*, and is naturally beautified with different colours, in the form of mountains, flowers, trees, and rivers. Ta-li has under its jurisdiction four cities of the second order, and three of the third; 1205 miles S.W. of Peking. N. lat. 25° 45'. E. long. 100°.

TALIA, in *Ancient Geography*, a town of the Upper Mœsia, on the route from Viminatum to Nicomedia. Ant. Itin.

TALJARA, in *Geography*, a town of Bengal; 46 miles S. of Curruckdeah.

TALIFAY, a town on the N. coast of the island of Luçon. N. lat. 14° 21'. E. long. 123° 24'.

TALIGALEA, in *Botany*, an unexplained name, Aublet Guian. 625. t. 252. Juss. 109, appears to be the same genus, and even the same species, as AMASONIA of Linnæus. (See that article.) The fruit of the latter having been examined in a drier state, may solve all the difficulty.

Aublet describes his only species, *T. campestris*, as an herb with a perennial root, sometimes creeping. Stems annual,

two or three feet high, simple, leafy, downy. *Leaves* alternate, stalked, elliptical, pointed, from three to six inches long, downy, with tooth-like serratures. The variety with a creeping *root* has smooth leaves, and we should presume it may be a distinct species. The *flowers* are yellow, about an inch long, numerous, in a long compound *cluster*, with ovate purple *bractes*. *Berry* black, with two hard *seeds*.—This plant grows abundantly in the sandy meadows of the island of Cayenne, as well as on the continent of South America, bearing flowers and fruit all summer long.

TALIGONG, in *Geography*, a town of Hindoostan, in the Carnatic; 7 miles N. of Terriore.

TALIGOV, a town of Ruffia, in the government of Riga; 24 miles N. of Dorpat.

TALIHOU, a small island, with a lazaretto, on the coast of France. At low-water the land which joins to the continent is dry; 3 miles N. of La Hogue. N. lat. $49^{\circ} 36'$. W. long. $1^{\circ} 9'$.

TALINA, a town of Peru; 50 miles E.S.E. of Lipes.

TA-LIN-HO, a town of Chinese Tartary. N. lat. $41^{\circ} 10'$. E. long. $120^{\circ} 50'$.

TALINUM, in *Botany*, a genus of Adanson's, well separated by him from the Linnæan PORTULACA. (See that article.) Its name no one, not even De Theis, has undertaken to explain; Adanson having given so many barbarous, and even arbitrary ones, that the inquiry might well be deemed alike hopeless and unprofitable. We conjecture, however, that he must have had in his mind the verb $\theta\alpha\lambda\lambda\omega$, to be verdant, or flourishing, and consequently $\theta\alpha\lambda\omega$, or $\theta\omega\lambda\omega$, a green lough; for he often wrote words with a T which in Greek begin with a θ ; and the above idea is suitable enough to the succulent, and durably verdant, habit of the genus. We hence learn the true accentuation of the word, *Talinum*. Ehrhart called this same genus *Rülingia*, after Dr. John Philip Rülings, who published at Gottingen, in 1774, a catalogue of the genera of plants, disposed in natural orders. Linnæus had formerly distinguished it by the name of *Anacampteros*.—Adans. Fam. v. 2. 245. Juss. 312. Willd. Sp. Pl. v. 2. 862. Ait. Hort. Kew. v. 3. 148. Pursh 365. Lamæck Illustr. t. 402. Gærtn. t. 128. (Rülingia; Ehrh. Beitr. v. 3. 132. *Orygia*; Forsk. Ægypt.-Arab. 103. *Anacampteros*; Linn. Gen. ed. 1. 152. Sims in Curt. Mag. p. 1367.)—Class and order, *Polyandria Monogynia*. (Dodecandria Monogynia, Willd.) Nat. Ord. *Succulentæ*, Linn. *Portulacæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of two or five oblong, rather unequal, permanent leaves. *Cor.* Petals five, spreading, ovate, obtuse, as long or longer than the calyx. *Stam.* Filaments numerous, capillary, not half so long as the corolla; anthers incumbent, oblong. *Pist.* Germen superior, roundish; style simple, about as long as the corolla; stigmas three, oblong, reflexed. *Peric.* Capsule ovate, of one cell, and three, five, or six valves. *Seeds* numerous, roundish, affixed to a globular central receptacle.

Elf. Ch. Petals five. Calyx of two or five leaves. Capsule superior, with from three to six valves, one cell, and many seeds.

Section 1. *Stipulas none. Seeds without wings.*

1. *T. triangulare.* Triangular-stalked Yellow Talinum. Willd. n. 1. Ait. n. 1. (*Portulaca triangularis*; Jacq. Amer. 147. Obs. fasc. 1. 35. t. 23. *P. racemosa*; Linn. Sp. Pl. 640. *Helianthemum frutescens*, *portulacæ folio*; Plum. Ic. 142. t. 150. f. 2.)—Leaves flat, channelled, wedge-shaped, emarginate, with a small point. Cluster simple, with a triangular stalk. Stem spreading.—Native of the sea-shores of the West Indies. Cultivated in Chelsea garden in 1739. Mr. Aiton says it blossoms in the stove,

most part of the summer. The *stem* is shrubby, two feet high, round, smooth, branched, decumbent in the lower part. *Leaves* scattered, about one and a half or two inches long, succulent, smooth, shining, brittle, entire at the edges; occasionally convex, being reflexed at the sides, tapering at the base into a short footstalk. *Flowers* two or more, on a terminal triangular stalk, very elegant, of a brilliant yellow, without scent. *Calyx* of two leaves. *Capsule* with three valves.

2. *T. crassecaule.* Thick-stemmed Red Talinum. (*T. crassifolium*; Willd. n. 2. *T. patens*; Andr. Repof. t. 253. Ait. n. 2. *Portulaca crassecaulis*; Jacq. Hort. Vind. v. 3. 29. t. 52. *P. crassifolia*; Murray in Linn. Syst. Veg. ed. 14. 446.)—Leaves flat, obovate, entire at the point. *Corymbs* compound, elongated. Stem erect.—Native probably of the West Indies. Jacquin cultivated it at Vienna, and we have seen it flowering in many of the English stoves. This differs from the former in its more erect and thicker *stem*, as well as in the fine pink colour of its *flowers*. The *leaves* moreover are not emarginate. The *corymbose*, or panicle, many-flowered *stalks*, at first terminal, are sometimes overtopped by the aggregate leafy *branches*, and thus become lateral, or axillary. Murray, from mere inadvertence in transcribing, altered Jacquin's original name, for one which has here no appropriate meaning.—Willdenow seems to have copied him, without seeing the work of Jacquin; which from this, and some other instances, we suspect he had not in his possession. We do not think it necessary to perpetuate such an error, any more than that of Andrews, who took this plant for Willdenow's *T. patens*, see n. 4.

3. *T. fruticosum.* Shrubby White Talinum. Willd. n. 7. (*Portulaca fruticosa*; Linn. Syst. Veg. ed. 13. 371. *P. paniculata*; Linn. Sp. Pl. 640. *P. americana latifolia erecta*, *floribus albis*; Comm. Hort. v. 1. 7. t. 4.)—Leaves flat, obovate, somewhat emarginate. *Corymbs* compound, elongated. Stem erect. Calyx of five leaves.—Native of the West Indies, or of South America. This species, a stranger to our gardens, appears to differ essentially from the two foregoing in having five leaves to the *calyx*, instead of two; and to say nothing of the white *petals*. In habit, *leaves*, and *inflorescences*, it comes very near the last. The *capsule* is said to consist of three valves in both.

4. *T. patens.* Panicle Red Talinum. Willd. n. 4. Haworth Succ. Pl. 123. (*T. paniculatum*; Gærtn. v. 2. 219. *Portulaca patens*; Linn. Mant. 242. Jacq. Hort. Vind. v. 2. 71. t. 151. *P. paniculata*; Jacq. Amer. 148.)—Leaves flat, obovate, obtuse. Panicle repeatedly compound, forked, many-flowered.—Native of rocks on the sea-coast of Martinico and Hispaniola. Jacquin. We have seen it in the English stoves, as Mr. Haworth likewise appears to have done, when he remarks that the *patens* of Andrews is a widely different plant. (See our 2d species.) That before us has an upright shrubby *stem*, one and a half or two feet high, branched; somewhat quadrangular below. *Leaves* scattered, or imperfectly opposite, obovate, lanceolate or oval, more or less obtuse, very smooth and juicy; the lower ones three inches long, the rest shorter; all tapering at the base into a short *footstalk*. *Panicles* solitary at the top of the stem and branches, erect, from six to ten inches long, with numerous, mostly opposite, repeatedly subdivided, and partly forked, slender, smooth, spreading stalks, accompanied here and there by small lanceolate *bractes* at their base. *Flowers* numerous, small, inodorous. *Calyx* of two orbicular, concave, red, widely spreading leaves. *Petals* five, obovate, red, thrice the size of the calyx, likewise widely spreading. *Capsule* globose, smaller than a peppercorn, its three valves, which Jacquin describes as double, or of

two layers, suspended from the top of three intermediate fibres. See Gærtner's figure and description, where the synonym of Commelin, which belongs to the foregoing, is very erroneously cited for the present species. This must have arisen from Linnæus's having once called the former *Portulaca paniculata*, and Gærtner's having copied the above synonym without examination.

5. *T. reflexum*. Panicked Yellow Talinum. Cavan. Ic. v. 1. t. 1. Haworth Succ. Pl. 124. Curt. Mag. t. 1543. Ait. Epit. 375. (*T. patens* β; Willd. n. 4.)—Leaves somewhat convex, elliptic-lanceolate, acute. Panicle twice compound, many-flowered.—Native of South America.—An annual or biennial, scarcely shrubby, plant in our stoves. Mr. Haworth observes, it is more tender, and much taller, than the last, of which Willdenow thought it a mere variety. We are not sure that the differences indicated in our specific characters are sufficient or permanent, not having had an opportunity of comparing the two plants. The flowers of *T. reflexum* being yellow, seems an important distinction in this genus. Both species are said to be abundantly propagated by seed.

6. *T. cuneifolium*. Wedge-leaved Talinum. Willd. n. 5. (*Portulaca cuneifolia*; Vahl Symb. v. 1. 33. *Orygia portulacifolia*; Forsk. Ægypt.-Arab. 103.)—Leaves flat, wedge-shaped, obtuse, with an occasional point. Panicle many-flowered; its lower branches umbellate, three-flowered.—Native of Arabia Felix.—A shrub three feet high. Leaves eatable, alternate, spreading, sessile, tapering at the base, about an inch long, thick and smooth. Calyx of two unequal leaves, deciduous. Petals of a violet red. Stamens green, with yellow anthers. Capsule three-angular, of three valves. Seeds black, compressed, smooth. Forskall.—Vahl says this species is akin to *T. patens*, n. 4, but differs in having thicker flower-stalks, the lower ones bearing three-flowered umbels.

7. *T. decumbens*. Decumbent Glauous Talinum. Willd. n. 6. (*Portulaca decumbens*; Vahl Symb. v. 1. 33. *Orygia decumbens*; Forsk. Ægypt.-Arab. 103.)—Leaves flat, obovate, pointed. Clusters axillary. Stem decumbent. Calyx of five leaves.—Native of Arabia Felix, in stony places near Musá, but not common. Forskall. Stem shrubby, with angular branches, clothed, like the rest of the plant, with a glaucous mealiness. Leaves distant, stalked, thickish, somewhat wavy. Clusters from the bosoms of the uppermost leaves, with an awl-shaped scale, or bractea, opposite to each partial stalk. Capsule of five valves. Vahl.—Forskall describes numerous lanceolate petals, about twenty, of a reddish violet; and five cells, as well as valves, to the capsule.

8. *T. teretifolium*. Cylindrical-leaved Talinum. Pursh n. 1.—“Leaves cylindrical, fleshy. Corymbs stalked, terminal.”—On sunny rocks in Delaware and Virginia, flowering in July. Perennial, Flowers purple. Pursh.

Section 2. *Stipulas within side of the leaves, jagged. Seeds winged.*

9. *T. Anacamperos*. Round-leaved Talinum. Willd. n. 3. Ait. n. 3. “Decand. Pl. Grasses, t. 3.” (*Rülingia Anacamperos*; Ehrh. Beitr. v. 3. 133. Haworth Succ. Pl. 124. *Portulaca Anacamperos*; Linn. Sp. Pl. 639. *P. africana sempervirens, flore rubicundo*; Comm. Hort. v. 2. 177. t. 89. *Telephium folio globofo*; Dill. Elth. 375. t. 281.)—Leaves ovate, acute, smooth; convex and tumid beneath. Stipulas filamentous, many times shorter than the leaves. Petals obovate.—Native of the Cape of Good Hope. Cultivated by Sherard in 1732. A greenhouse plant, flowering in July. A humble shrubby species, whose extremely thick and succulent leaves, about an inch long, give it the habit of an *Aloe*. They are sessile, of a pale glaucous green, not

shining; their upper side nearly flat, with a longitudinal furrow; the under very convex. *Stipulas* short, in many capillary segments. *Flowers* crimson, the size of our second or third species, in long-stalked terminal simple clusters, which are sometimes two together. *Calyx* of two leaves. *Petals* somewhat pointed. The seeds are said to be winged. Ehrhart calls them *arillata*, tunicated.—The specific name, borrowed from Pliny, derived from *ανακαμπερα*, to return, and *ερος*, love, was at first adopted by Linnæus as a generic appellation for the present plant, when he considered it as a distinct genus from *Portulaca*, in his earlier publications. But this name, and the foolish superstition to which it alludes, of the very touch of the herb restoring alienated love, rather belongs to the *Sedum Anacamperos* of Linnæus, and its near relation *S. Telephium*. See *SEDUM*.

10. *T. arachnoides*. Cobweb Talinum. Ait. n. 4. (*Anacamperos arachnoides*; Sims in Curt. Mag. t. 1368. *Rülingia arachnoides*; Haworth Succ. Pl. 125.)—Leaves elliptical, acute; slightly convex, and covered with cobweb-like down above; tumid beneath. Stipulas filamentous, shorter than the leaves. Petals elliptical.—Found by Mr. Maffon at the Cape of Good Hope, and sent to Kew about the year 1790. It is treated like the last, and agrees with that species in general habit, though smaller in size. The leaves are less glaucous; the lower ones covered with a kind of web. *Stipulas* longer and more robust. *Flowers* white, with a faint blush. Seeds observed by Mr. Haworth to be less winged.—The leaves are represented in the Botanical Magazine with a tinge of purplish-brown. Perhaps Mr. Haworth's *Rülingia rubens*, n. 3, may be only a higher-coloured variety.

11. *T. filamentosum*. Thready Talinum. Ait. n. 5. (*Anacamperos filamentosa*; Sims in Curt. Mag. t. 1367. *Rülingia filamentosa*; Haworth Succ. Pl. 125.)—Leaves ovate, bluntish, tumid and covered with cobweb-like down on both sides. Stipulas filamentous, longer than the leaves. Petals lanceolate.—Found by Mr. Maffon, at the Cape of Good Hope, and sent to Kew a few years after the last, from which it differs in having smaller, blunter leaves, and much longer, more conspicuous, stipulas, whose segments are linear and flattened, like shavings of horn. The petals are rose-coloured, and elliptic-lanceolate, very fugacious, as in the two foregoing species. We have never seen Mr. Haworth's *Rülingia lanceolata*, n. 5, but it seems, by his definition, nearly akin to this.

The winged seeds can hardly entitle the species of this section to form a separate genus, there being so little difference in habit. If they did, the name of *Rülingia* must certainly be preferred to *Anacamperos*, the latter, notwithstanding its right of priority, having been arbitrarily and erroneously applied to these Cape plants, with which the ancients were of course unacquainted. See our remark under the 9th species.

TALIO, *Lex Talionis*, or *Pena Talionis*; a retaliation, or punishment, by which an evil is returned perfectly like that committed against us by another; which is what we usually express by the words, *eye for eye, tooth for tooth*.

The *pena talionis* was enjoined by the law of Moses, among the Jews; it was esteemed a natural piece of justice, and yet the Romans set it aside, inasmuch as such a parity or equality of punishment could not always be observed. For this reason the prætor allowed such as had suffered an injury to make an estimate of it in money, that justice might be done him that way; only referring to himself the power of moderating the same. And this was what was constantly practised, and thus the *pena talionis* became quite disused with them.

TALISIA, in Botany, a barbarous name of Aublet's, which

which he appears to have fabricated out of the Caribbean appellation of the plant in question, *Toulichi*. We should be inexcusable in giving more than a temporary sanction to such a name, till the genus is either better known than at present, or set altogether aside.—Aubl. Guian. 349. Juss. 247. Lamarek Illustr. t. 310.—Class and order, *Ocandria Monogynia*. Nat. Ord. *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, acute segments. *Cor.* Petals five, ovate, inserted into the orbicular receptacle of the flower beneath the germen. Nectary of five short, hairy, upright scales, one inserted into the base of each petal, covering the stamens. *Stam.* Filaments eight, short, inserted into the orbicular receptacle; anthers oblong, of two cells. *Pist.* Germen superior, minute, roundish, of four cells; style one, very short; stigma simple, obtuse. *Peric.* unknown.

Ess. Ch. Calyx in five deep segments. Petals five. Nectary of five hairy scales, attached to the petals. Germen of four cells.

1. *T. guianensis*. Toulichi of Guiana. Aubl. Guian. 349. t. 136.—Native of banks of rivers in Guiana, flowering in October.—A shrub, whose trunk is three or four feet high, and as many inches in diameter, with a greyish bark, and whitish wood; the branches long, compound, variously spreading. *Leaves* alternate, pinnate, very large, each consisting of about thirty alternate, stalked, elliptic-lanceolate, pointed, entire, smooth, veiny leaflets, besides an odd one, from five to six inches long, and above one broad. *Clusters* axillary and terminal, doubly compound, many-flowered, all over of a fine rose-colour, with a small scaly bractea under each subdivision. *Flowers* small, in little tufts, nearly sessile.—Nothing is known of the fruit, except that the germen has four cells, nor is any thing recorded concerning the qualities or uses of this plant.

TALISKERAN, in *Geography*, a town of Persia, in the province of Adirbeitzan; 100 miles N.N.E. of Ardebil.

TALISMANS, magical figures engraven or cut under certain superstitious observances of the characteristics and configurations of the heavens; to which some astrologers, hermetical philosophers, and other adepts, attribute marvelous virtues, particularly that of calling down celestial influences.

The word is pure Arabic; though Menage, after Salmasius, thinks it may come from the Greek *τῆλεμα*, operation, or consecration. Borel says it is Persian, and signifies literally an engraven constellation. Others derive it a *talamacis literis*, which are mysterious characters, or cyphers, used by forcerers, thus called from *talamasca*, a phantom, or illusion.

The author of a book, entitled, *Talismans justifiez*, says, a talisman is the seal, figure, character, or image of a heavenly sign, constellation, or planet, engraven on a sympathetic stone, or on a metal corresponding to the star, &c. in order to receive its influences.

The talismans of the Samothracians, so famous of old, were pieces of iron, formed into certain images, and set in rings, &c. They were held preservatives against all kinds of evils. There were other talismans taken from vegetables, and others from minerals.

In the general, we may distinguish three kinds of talismans. *Astronomical*, which are known by the signs or constellations of the heavens engraven on them, with other figures, and some unintelligible characters. *Magical*, which bear very extraordinary figures, with superstitious words and names of angels unheard of. And *mist*, which consist of signs, and barbarous words; but have no superstitious ones, or names of angels.

Some rabbins maintain, that the brazen serpent, raised by Moses in the wilderness, for the destruction of the serpents that annoyed the Israelites, was properly a talisman.

All the miraculous things wrought by Apollonius Tyannus are attributed to the virtue and influence of talismans: and that wizard is even said by some to have been the inventor of talismans.

Some authors take several Runic medals, at least medals whose inscriptions are in Runic characters, for talismans; it being notorious; that the northern nations, in their heathen state, were much devoted to them. M. Keder, however, has shewn, that the medals here spoken of are quite other things than talismans.

TALISSE, in *Geography*, a small island in the East Indian sea, near the N. coast of the island of Celebes. N. lat. $1^{\circ} 40'$. E. long. $124^{\circ} 50'$.

TALK, in *Mineralogy*. See TALC.

TALKAN, in *Geography*, a town of Persia, in the province of Irak; 30 miles E. of Sultania.

TALKEAVE, a town of Persia, in Khorassan; 50 miles E. of Tabaskili.—Also, a town of Persia, in Segeftan; 21 miles S.W. of Kin.

TALKHAN, a town of Grand Bucharia; 80 miles S.S.W. of Balk.

TALKING. See SPEAKING.

TALLAGH, in *Geography*, a post-town of the county of Dublin, Ireland, where is the ancient and noble residence of the archbishops of Dublin; 5 miles S.W. by W. from Dublin.

TALLANO, a town of Corsica, and capital of a district, in the department of the Liamone, situated in a bay of the Mediterranean, called the "Gulf of Tallano;" 30 miles S.S.W. of Corte. N. lat. $41^{\circ} 33'$. E. long. $9^{\circ} 11'$.

TALLAPOUR, a town of Hindoostan, in Oude; 22 miles N.E. of Lucknow.

TALLARAPESCET, a town of Persia, in the province of Mazanderan; 21 miles S. of Fehrabad.

TALLARD, a town of France, in the department of the Higher Alps, on the Durance; 9 miles S. of Gap.

TALLARO, in *Commerce*, a silver coin of Tuscany, Venice, and Ragusa. At Florence the tallaro is = 6 lire or 9 paoli, the lire being worth about 8d. The new tallari of Ragusa, called libertine, coined between 1791 and 1794, are of the weight of 1 oz. 10 carats, containing 9 parts of pure silver to 6 of alloy; and the value of the tallaro was reckoned at 80 grossetti. Since 1796 there have been coined ducats of 40 grossetti, containing 9 parts of pure silver and 11 of alloy. The ducat of 1796 is worth $13\frac{1}{4}d.$ sterling, which is nearly the value of the Turkish piastre of the latest coinage.

By Mr. Bingley's assay, the mint price of silver in England being 5s. 2d. per ounce standard, the tallaro of Venice ($\frac{1}{2}$, &c. in proportion) is worse than English standard (W.) 1 oz. 3 dwts., its weight 18 dwts. $10\frac{3}{4}$ grs., its content in pure silver 367.1 grs., and value in sterling 4s. $3\frac{1}{4}d.$ The tallaro and its divisions are marked with the head of a woman, legend, *Repubblica Veneta*; reverse, a winged lion, and a book; legend, the reigning doge's name, thus *Paulo Rainario duca*.

The assay of the tallaro of Ragusa, or Ragusian of 1759, is W. 4 oz. 2 dwts., its weight 18 dwts. $7\frac{1}{2}$ grs., its content in pure silver 256.4 grs., and its sterling value 2s. $11\frac{3}{4}d.$ That of 1774, W. 4 oz. 4 dwts., weight 18 dwts. $8\frac{1}{2}$ grs., content in pure silver 253.3 grs., and value 2s. $11\frac{1}{4}d.$ That of 1794, W. 3 oz. 19 dwts., weight 18 dwts. $17\frac{1}{4}$ grs., content 267.6 grs., and sterling value 3s. $1\frac{1}{4}d.$ The ducat of

1797, W. 5oz. 11 dwts., weight 8 dwts. 17 $\frac{1}{4}$ grs., content 97 grs., and value 1s. 1 $\frac{1}{2}$ d.

The tallaro of Ragusa is marked with the head of the chief magistrate, called the rector; legend, *Rektor Reip. Rhacusin*; reverse, arms of the city; legend, *Ducat et Sem. Reip. Rac.* In the Levant, and other places, the term tallaro is applied to dollars in general. Kelly's Cambist.

TALLEVENDE, in *Geography*, a town of France, in the department of the Calvados, containing near 3000 inhabitants, chiefly employed in the manufacture of earthenware; 2 miles S.W. of Vire.

TALLIAGE, **TALLAGIUM**, a certain rate, according to which barons and knights were anciently taxed by the king towards the expences of the state, and inferior tenants by their lords, on certain occasions.

That raised to the king was on his demesnes, escheats, and wardships, and upon the cities and burghs of the realm. When it was paid out of knights' fees, it was called *scutage* (which fee); when by cities and burghs, *talliage*; when upon lands not of a military tenure, *hideage*; which fee.

This latter talliage of the customary tenants was sometimes fixed and certain, and sometimes at the pleasure of the lord; and was also sometimes compounded for.

Talliages were anciently called *cuttings*; which name is still retained in Ireland, though in a different signification.

Talliage, says sir Ed. Coke, is a general name including all taxes; and is derived from the French *taille*, *tax*, founded on the tally of petty tradesmen; as the country people appointed to collect it, not being able to write, scored down what they received on tallies. See **LAND-TAX** and **SUBSIDY**.

TALLIKA, in *Geography*, a town of Africa, in the kingdom of Bondou, inhabited by Foulahs of the Mahometan religion, in the road of the caravans; 70 miles W.S.W. of Fatteconda. N. lat. 13° 56'. W. long. 11° 40'.

TALLIPOUR, a town of Hindoostan, in Bahar; 10 miles S.E. of Hajypour.

TALLIS, **THOMAS**, in *Biography*, the master of Bird, and one of the greatest musicians; not only of this country, but of all Europe, during the 16th century, in which many able contrapuntists flourished.

He was born early in the reign of Henry VIII.; but though it has frequently been asserted that he was organist of the chapel royal during the reigns of that monarch, Edward VI., queen Mary, and queen Elizabeth, yet it would be difficult to prove that, in the three first of these reigns, laymen were ever appointed to any such office. In the reign of Henry, and his daughter Mary, when the Roman Catholic religion prevailed, the organ, in convents, was usually played by monks; and in cathedrals and collegiate churches and chapels, by the canons, and others of the priesthood. The first lay organists of the chapel royal upon record were Dr. Tye, Blithman, the master of Dr. Bull, Tallis, and Bird; all during the reign of queen Elizabeth.

Though the melody or plain-song of the cathedral service was first adjusted to English words by Marbeck, yet Tallis enriched it with harmony. Indeed the melody used by Tallis is not exactly similar to that of Marbeck; it is only of the same kind; consisting of fragments of the ancient ecclesiastical canto fermo. But the harmony in which he has clothed it is admirable; and the modulation being so antique, chiefly in common chords or fundamental harmony to each note of the diatonic scale, often where the moderns have sixths, sevenths, and their inversions, produces a solemn and very different effect from any music that has been composed during the last century. As all melody, in which the semitones are avoided, must resemble that of Scotland;

so all harmony, in which neither the *tritonus* nor false fifth occurs, and where the second, third, and sixth of the key, are only accompanied with common chords, must remind us of that which prevailed in the sixteenth century; and though so ancient, appear new to our ears, from its long disuse.

There are two compositions by Tallis for the organ, preserved in queen Elizabeth's Virginal Book, one of which is dated 1561, and the other 1564; both built upon a dull and unmeaning ground, or fragment of plain-chant (*felix namque*), and both alike dry, elaborate, and difficult, to hands formed by modern music. The little melody and rhythm in the compositions of these times required all the harmony that could be crowded into them. Notes are multiplied without end, and difficulties created without effect. It is not by the instrumental music, which had been but little cultivated, that we must judge of the genius of old masters; but by vocal, in parts: where the harmony and contrivance compensate for want of accent, taste, and invention. The Latin motets and hymns, or "Cantiones sacræ," which he published jointly with those of his disciple Bird, are perhaps the best of his compositions that have been preserved. These appeared in 1575, under the following title: "Cantiones quæ ab Argumento factæ vocantur quinque et sex Partium. Autoribus Thoma Tallisso et Gulielmo Birdo, Anglis, Serenissimæ Reginæ Majestati à privato facello Generosis et Organistis." At the time of this publication, a very arbitrary and monopolising patent was granted by queen Elizabeth to these composers, for twenty-one years, not only for the publication of their own productions, vocal and instrumental, but those of all other musicians, whether English, French, or Italian, as well as for the sole ruling and vending of music-paper.

Most of these excellent compositions, of which the words were originally Latin, were afterwards adjusted to English words by Dr. Aldrich, and others, for the use of our cathedrals. The canons, inversions, augmentations, diminutions, and other learned and fashionable contrivances of the times, which were of very difficult accomplishment, are carried to a wonderful degree of ingenuity in these productions.

Dr. Thomas Tudway, of Cambridge, made a very valuable collection of English church music, in score, from the Reformation to the Restoration, in six volumes, thick 4to. for Lord Harley, afterwards earl of Oxford, which is now among the Harleian manuscripts, in the British Museum, No. 7337. In the first volume of this collection we have the whole service of Tallis in D minor, in four parts, consisting of the *Te Deum*, *Benedictus*, *Kyrie Eleison*, *Credo*, *Magnificat*, *Nunc Dimittis*, and *Litany*, as printed in 1760, by Dr. Boyce; with several anthems in four and five parts; as, "Wipe away my sins;" "With all our hearts and mouths;" "O Lord, give thy holy spirit;" "I call and cry;" and his anthem, "Discomfit them, O Lord!" erroneously said by Dr. Tudway to have been set for the victory over the Spanish Armada, 1588.

In Christ-Church, Oxford, are manuscript scores of his Præces, Litany, and Anthems, among others by Bird, Farrant, Bull, Gibbons, and Child. Five of his motets and full anthems, in five parts, to Latin and English words, are likewise here preserved among the works of other English masters, in Dr. Aldrich's collection. But the most curious and extraordinary of all his labours was his "Song of forty Parts," which is still subsisting, and now before us. This wonderful effort of harmonical abilities is not divided into choirs of four parts: soprano, altus, tenor, and base, in each, like the compositions *a molti cori*, of Benevoli, and others; but consists of eight trebles, placed under each other;

other; eight *mezzi soprani*, or mean parts; eight counter-tenors; eight tenors; and eight basses; with one line allotted to the organ. All these several parts, as may be imagined, are not in simple counterpoint, or filled up in mere harmony, without meaning or design, but have each a share in the short subjects of fugue and imitation, which are introduced upon every change of words. The first subject is begun in G, by the first *mezzo soprano*, or *medius*, and answered in D, the fifth above, by the first soprano; the second *medius* in like manner beginning in G, is answered in the octave below by the first tenor, and that by the first counter-tenor in D, the fifth above; then the first bass has the subject in D, the eighth below the counter-tenor; and thus all the forty *real* parts are severally introduced in the course of thirty-nine bars, when the whole vocal phalanx is employed at once, during six bars more. After which a new subject is led off by the lowest bass, and pursued by other parts, severally, for about twenty-four bars, when there is a general chorus of all the parts; and thus this stupendous, though perhaps Gothic, specimen of human labour and intellect, is carried on in alternate flight, pursuit, attack, and choral union to the end; when the *Polyphonic phenomenon* is terminated by twelve bars of universal chorus, in quadragesimal harmony. The entire composition consists of one hundred and thirty-eight bars, in *alla breve* time.

This venerable musician died in November, 1585, and was buried in the old parish church of Greenwich, in Kent. The following epitaph, which Dr. Boyce has printed in the first volume of his Collection of Cathedral Music, Strype, in his Continuation of Stow's Survey, printed 1720, says he found engraved in Gothic letters, on a brass plate in the chancel.

"Entered here doth ly a worthy wyght,
Who for long tyme in musick bore the bell:
His name to shew was Thomas Tallis hyght,
In honest vertuous lyff he did excell.
He serv'd long tyme in chappel with grete prayfe
Fower sovereyngnes reignes, (a thing not often seene);
I mean king Henry and prince Edward's dayes,
Quene Marie, and Elizabeth our quene,
He maryed was, though children he had none,
And lyv'd in love full three and thirty yeres
With loyal spowfe, whos name yclept was Jone,
Who here entomb'd, him company now bears.
As he dyd lyve, so also dyd he dy,
In myld and quyet fort, O happy man!
To God ful oft for mercy did he cry,
Wherefore he lyves, let Deth do what he can."

The stone to which this plate was affixed had been renewed by Dr. Aldrich; but the old church having been pulled down, about the year 1720, in order to be rebuilt, no memorial remains of Tallis, or any other illustrious person, who had been interred there anterior to that period.

TALLOW, a sort of animal fat, melted down and clarified. There are scarcely any animals but a sort of tallow may be prepared from; but those which yield the most, and of which the most use is made, are the horse, bullock, sheep, hog, goat, deer, bear, and viper. Some of which tallows, or fats, are used in medicine, and called *axungia*.

Most of the rest are used in the making of soap, and the dressing of leather; but chiefly in making of candles. For this purpose, large quantities are annually imported from Russia in casks. (See **CANDLE**.) Tallow-chandlers also melt tallow, which is done by chopping the fat, as it is taken from oxen and sheep, and then boiling it for some time in a large copper; and when the tallow is extracted by this

process, the remainder is subjected to the operation of a strong iron press; and the cake that is left, after the tallow is expressed from it, is called a "greave." With this dogs are fed, and most of the ducks that are reared in the vale of Aylebury, and which supply the London markets. It is also sometimes given to oxen and pigs, but certainly without meliorating the flavour of the meat.

It has been observed, that candles should be made without any admixture of oil or grease; and when laid up, should be preserved from the action of the atmosphere. For this purpose, some persons keep their candles closely covered up in bran. If tallows are weak, a part soon becomes converted to an acid by exposure to the air; and this renders the whole, when melted together, unfit for candles. Tallows, also, that contain a large portion of sebatic acid, require much more barilla than good tallow, in the manufacture of soap, and yet produce a less quantity. Foreign tallows, which frequently contain a large portion of acid, rendering them inferior to the English, may be purified at an insignificant expence by chemical means; and by the proper application of chemical agents, other brown tallows may be rendered beautifully white, and fit for the best purposes. The mode, says a chemical writer of reputation, which naturally presents itself as the best for separating the sebatic acid from tallow, is that of melting it in water containing some alkali; but old tallows may in general be sufficiently purified from their rancidity by melting them upon lime-water, and giving a considerable agitation to the whole mixture; for when the water is again suffered to subside, it will be found to be offensive in smell, and to have subtracted most of the impurities of the tallow. If the tallow, however, should not be sufficiently purified, a repetition of this process would completely effect it. Parkes's Chemical Essays, vol. i. p. 67, &c.

TALLOW-TREE, in China, is a tree growing in great plenty in that country, which produces a substance like our tallow, and serving for the same purpose. See **CORON Sebiferum**.

All the preparation they give it, is to melt it down and mix a little oil with it, to make it softer, and more pliant. It is true, their candles made of it yield a thicker smoke, and a dimmer light than ours; but those defects are owing, in a great measure, to the wicks, which are not of cotton, but only a little rod or switch of dry light wood, covered with the pith of a rush, wound round it; which being very porous, serves to filtrate the minute parts of the tallow, attracted by the burning stick, which by this means is kept burning.

TALLOW-CHANDLERS' GREAVES, in *Agriculture*, the refuse of tallow-chandlery, which is found at the bottom of the pan, after the melting of tallow, in a sort of cake, and which is an excellent *manure*; which see.

TALLOW, in *Geography*, a post-town of the county of Waterford, Ireland, situated within half a mile of the river Bride, on which there is a village called Tallow-bridge. It was a borough which returned two members, previous to the Union. It is 104 miles S.W. by S. from Dublin, and 4 S. from Lismore.

TALLOW POINT, a mark for anchoring in the harbour of Port Royal, in Jamaica.

TALLOWING, in *Rural Economy*, a term applied to the property or means of forming tallow internally in animals of some kinds, especially those of the sheep and neat cattle sorts. It has been stated in the corrected *Agricultural Report* of the County of Suffex, that it is by no means a settled point upon the South Downs of that district, how far a sheep, which gathers its fat upon the intestines, is or is not preferable to another which collects it upon the back and the neck,

neck. The Leicestershire graziers, it is said, contending as much for the latter as the former, is considered as a test of merit in Norfolk, and various other counties. But when it is considered, that it requires a certain portion of food to create a given quantity of fat, the question is, it is thought, which is the best part to collect it upon,—within or without? As long as the fat of the latter will sell at more than one-third of the other, it would seem, it is said, that there cannot be a doubt which of the two is preferable; and that, upon the principle of food eaten to produce the tallow or fat, that which tallows the least is the best breed. The tallow, with the major part of the fifth quarter, is all the butcher's profit, it is said, who would no doubt encourage that breed which tallows best, and yields most offal.

It is noticed, however, that the South Down sheep are not great tallowers, compared with some other sorts; but that what they lose in tallow, they make up in a disposition to fatten. The tallow of a wether, in common management, will, it is said, generally average from an eighth to a tenth part of its dead weight. In a fat wether of Mr. Ellman's, one-seventh part of the dead weight was, it is said, inside fat (caul and loose fat); and that in another which was since killed, one-sixth was inside fat. In others, too, that have been slaughtered, the variation has been found from a seventh to a tenth. The quantity of inside fat depends, it is said, much upon the age and time of fattening. It gathers itself much more in old sheep than in young ones.

The bad ill-formed breeds of sheep, for the most part, tallow in the largest and most favourable manner; and the same is mostly the case in neat-cattle stock, as those which have the best forms and dispositions for fattening have commonly the least property of tallowing well, or afford the least proof, as it is often called.

In regard to the superiority of fat meat, it may be just noticed that, in some great thoroughfares for travelling, the inn-keepers agree with the butchers to give them a penny the pound above the common price for mutton, provided it be very fat. It is likewise the same with beef. This is said to be the case at Petersfield, and to strongly shew that very fat mutton, or meat of any kind, will go much farther than that which is not equally so. It, however, makes against tallowing in animals of these kinds. See *LIVE-Stock* and *SHEEP*.

TALLWATER, in *Geography*, a river of Ireland, in the county of Armagh, which runs with the Callen into Blackwater, near Charlemont.

TALLY, *Taille*, or *Taille*, a piece of wood on which retail traders use to score or mark, by notches or incisions, the several quantities of goods they deliver out on credit, to save the trouble of writing down so many little articles in books.

Each score consists of two pieces of wood, or rather of a single piece cleft length-wise, the parts of which falling in with one another, things delivered are scored on both at the same time; the seller keeping one, and the buyer the other.

Tallies are taken as evidences in courts of justice, as much as books. The ancient way of keeping all accounts was by tallies; the debtor keeping one part, and the creditor the other. Hence the *tallier* of the exchequer, now called the *teller*.

There are three kinds of tallies mentioned in our statutes, and long used in the exchequer; *viz.*

TALLIES of Loans, one part of which is kept in the exchequer, and the other part given to particular persons, in lieu of an obligation for the monies they have lent to the government on acts of parliament. This last part is called

the *stock*, and the former the *counter-stock*, or the counter-tail.

The tallies are numbered, and bear the person's name, and the sum lent: thus we say, the tallies, N^o. have been paid, or discharged; tallies are risen, fallen, 4, 5, &c.

TALLIES, or *Tailles of Debt*, are a kind of acquittances for debts paid to the king.

E. gr. The university of Cambridge pays yearly 10*l.* for such things as are by charter granted them in fee-farm. He that pays this receives a *taille*, or tally, for his discharge, with which, or a note of it, he repairs to the clerk of the pipe, and there for the tally receives a full discharge on parchment.

TALLIES of Reward, or allowance. These are made to sheriffs, for such matters as (to their charge) they have performed in their office, or by such money as is by course cast on them in their accounts, but which they cannot levy.

In the exchequer there is a *tally-court*, where attend the two deputy chamberlains of the exchequer, and the tally-cutter.

TALLY-Counter. See *COUNTER*.

TALLIES, Cutter of the. See *CUTTER*.

TALLY, Petty. See *PETTY*.

TALLIES, Writer of. See *WRITER*.

TALLY the Sheets, at sea, a word of command, when the sheets of a main-sail or fore-sail are to be hauled aft. See *SHEETS*.

TALLY for Flowers and Plants, in *Gardening*, that sort of mark or contrivance, either by pieces of lead or slips of wood, employed for distinguishing them.

The practice of marking flowers, trees, and plants, with tallies of some kind or other, is always highly useful and necessary in regulating their culture, as well as for many other purposes.

TALLYOOR, in *Geography*, a town of Hindoostan, in Mysore; 8 miles N.W. of Dindigul.

TALMAS, a town of France, in the department of the Somme; 9 miles S. of Doullens.

TALMAY, a town of France, in the department of the Côte d'Or, at the union of the Yonne and the Saône; 18 miles N.E. of Dijon.

TALMOND, a sea-port town of France, in the department of the Lower Charente, on the right side of the Gironde, with a harbour; 18 miles S.W. of Saintes.

TALMONT, a town of France, in the department of the Vendée; 6 miles E.S.E. of Sables d'Olonne.

TALMUD, or *THALMUD*, from תלמוד, *doctrina*, לומד, *he taught*, a Jewish book, which contains a collection of all that relates to the explication of their law.

The Talmud is the body of the Hebrew law; a compilation of explications of the duties imposed on the people, either in scripture, or by tradition, or by authority of their doctors, or by custom, or even by superstition: to speak more plainly still, it is the course of cases of conscience, or of moral theology, in which the duties are explained, and the doubts cleared, not by reasoning, but generally by authority, by the custom of the nation, and by the decisions of the most approved of the ancient doctors.

The Talmud consists of two general parts, the one called the *Mischna*, the other the *Gemara*; which first part is also frequently called absolutely the "Talmud," the general name of the whole work.

The Jews divide their law into *written*, which is that contained in the books of Moses; and *unwritten*, which is that conveyed by tradition. This latter is, in effect, no other than a gloss or interpretation of the former, given by the ancient rabbins.

The Talmud then contains the traditions of the Jews, their polity, doctrine, and ceremonies, which they observe as religiously as the law of God itself: they would never put them in writing till they were compelled to it by the destruction of Jerusalem, and till they saw themselves dispersed throughout the world.

They had two famous schools; the one at Babylon, and the other at Jerusalem: in these they made two several collections of those traditions; the first at Jerusalem, the other at Babylon; but both called Talmud, both exceedingly revered, especially the Babylonian, though full of extravagancies. This was compiled by the Jews of Mesopotamia, about 500 years after Christ, according to Buxtorf: but Father Morinus offers several reasons to prove that it was not finished till the year 700. The last edition of this Talmud, at Amsterdam, is in twelve folios.

The Talmud of Jerusalem is the least esteemed. It was compiled by the Jews of that city, and particularly by Rabbi Jochanan, rector of the academy at Tiberias, about 300 years after Christ, according to Buxtorf; but Father Morinus, in his "Exercitationes Biblicæ," lib. ii. exerc. 6. judges, from several barbarous terms found in it, of Vandalic or Gothic extraction, that it did not appear till the fifth century. This is published in one large folio.

The Babylonian Talmud consists of two parts: the one the text, the other the gloss or comment: the comment, called the *Gemara*, contains the decision of the Jewish doctors, and their expositions of the text.—This we find stuffed with dreams and chimeras; together with much ignorance, and many impertinent questions and disputations: the style is also very coarse. On the contrary, the text called the *Mischna*, is written in a tolerably pure style, and the reasonings generally much more solid.

The Jews pretend that this was composed by Rabbi Juda, surnamed the *Saint*; and that God revealed to him the doctrine, and the chief mysteries of it. But this is only to be understood of the *Mischna*, not of the *Gemara*, the compilation of which was not begun till the sixth century, after the destruction of the second temple.

Rabbi Juda is said to have composed the *Mischna* under the empire of Antoninus, in the second century; but they do not all agree about this antiquity, some carrying it back much farther.

It is the Talmud of Babylon that is usually read, and most frequently consulted, among the Jews; so that when they say simply "the Talmud," they always meant this; never quoting the other without the addition of Jerusalem.

Maimonides has made an abridgment of the Talmud, which Scaliger prefers to the Talmud itself; as being purged of many of the fables of which the other is full. It is a system of the laws and customs of the Jews, both of their civil and their canon law, and the best of their traditions.

About the year 1236, a Jew of Rochelle, well versed in the Hebrew, becoming Christian, made a journey to pope Gregory IX., and discovered to him a number of errors in the Talmud: these the pope sent, in thirty-nine articles, to the archbishops of France, with a letter, appointing them to seize the books of the Jews, and to burn all such as should contain those errors: in consequence of which order, about twenty cart-loads of Hebrew books were burnt. He wrote to the same effect to the kings of England, France, Aragon, Castile, &c.

His successor, Innocent IV., giving commission to his legate, Eudes de Chateauroux, to examine the Talmud, and other Jewish books, more carefully, and to tolerate such errors as were not contrary to the Christian religion; the legate wrote to the pope, that to tolerate them was to ap-

prove them; and the 15th of May, 1248, he also condemn'd them juridically to the flames; and Paul IV. ordered 12,000 volumes of the Talmud to be consumed; and Clement VIII. ordered all the talmudic books that could be found to be destroyed; a zeal worthy of the Papal see! See *MISCHNA*, *GEMARA*, *CARAITES*, and *RABBINISTS*.

TALO-CHAN, in *Geography*, a small island near the coast of China. N. lat. 29° 57'. E. long. 122° 4'.

TALOIRE, a town of France, in the department of Mont Blanc; 8 miles S.S.E. of Annecy.

TALON, in *Ornithology*, the claw of a bird.

TALON, in *Architecture*, a kind of moulding, consisting of a cymatium, crowned with a square fillet; frequently found to terminate ornaments of joiners' work, as those of doors, &c.

The word is French, and literally signifies *heel*.

The talon, more properly so called, is a moulding concave at the bottom, and convex at top; having an effect just opposite to the doucine.

When the concave part is at top, it is called an *inverted talon*.

The talon is usually called by our English workmen *ogee*, or *O.G.* and by authors an *upright* or *inverted cymatium*.

TALOO, in *Geography*, a harbour on the N. coast of *Eimeo*; which see.

TALOVKA, a river of Russia, which unites with the *Analik*, and runs with it into the *Irgis*, 32 miles E. of *Volk*, in the government of *Saratov*.

TALPA, the *Mole*, in *Zoology*, a genus of the *Mammalia Feræ*, the characters of which are, that the front teeth in the upper jaw are six and unequal, those in the lower jaw are eight; the canine teeth are one on each side, the upper ones being the largest; and that the grinders are seven in the upper jaw, and six in the lower. *Gmelin* enumerates four species, besides several varieties.

Species.

EUROPEA; Common Mole. Has a short tail, and pentadactylous or five-toed feet. The body is thick and cylindrical; the snout slender, but very strong and tendinous; the head not distinguished from the body by any appearance of neck; the legs so extremely short, as scarcely to project perceptibly from the body; the fore-feet situated obliquely outwards, excessively strong and broad, and furnished with very large and stout claws, so as to give the animal the power of working under the surface with the utmost ease and readiness; the hind-feet are small in proportion to the fore-feet, and are calculated for throwing back with ease the mould from behind the creature, during his subterraneous progress; the tail is short and small; the skin is much thicker and tougher in proportion than in other quadrupeds, and the fur with which it is covered equally surpasses that of other animals in fineness and softness. The muscular strength of the mole is very great, and it is enabled to force itself into the ground with an extraordinary degree of celerity. The general length of the mole is about five inches and three quarters, exclusive of the tail, which measures one inch. This animal is supposed to possess the power of hearing in an exquisite degree; and if at any time it emerges from a subterraneous retreat, instantly disappears on the approach of any danger. When first taken, either by digging it out or otherwise, it utters a shrill scream, and prepares for defence by exerting the strength of its claws and teeth. According to the count de Buffon, so lively and reciprocal an attachment subsists between the male and female, that they seem to dread or disrelish all other society.

It has been doubted whether the mole has eyes adapted to vision,

vision, or merely for the purpose of apprising it of the approach of light, so as to warn it of the danger of exposure. Galen is of the former opinion. Sir Thomas Brown refers this to the class of vulgar errors; but Derham, by dissection, and the aid of a microscope, confirmed the opinion of Galen. This animal is said to feed not only on worms and insects, &c. but on the roots of vegetables; however, it is more carnivorous than frugivorous. In particular circumstances it is very fierce and voracious. Without damp mould for its residence, it is kept alive with difficulty in a state of confinement. Like other animals of a black colour, the mole is sometimes found perfectly white, or cream-coloured, and sometimes spotted. Gmelin reckons four varieties, *viz.* the variegated or spotted mole of Edwards, the white, the yellow, and the cinereous. Of its surprising power in swimming, we have a curious instance recorded in the 3d volume of the Transactions of the Linnæan Society; which is that of a mole that was seen swimming towards a small island in the middle of the loch of Clunie, in Scotland, at the distance of 180 yards from the land. Linnæus and Gmelin affirm that the mole passes the winter in a state of torpidity; but this is contradicted by Buffon, and he alleges facts to prove the contrary. The mole is said to be unknown in Ireland. In Siberia it attains a larger size than in Europe, and its fur is so soft and beautiful, that it would make the most elegant articles of dress, were it not for the difficulty of curing and dressing the skin. See MOLE.

ASIATICA. Has no tail, and tridactylous fore-feet. This is the Siberian mole of Pennant. It is somewhat smaller than the common mole, its length being four inches; and is a native of the Cape of Good Hope.

LONGICAUDATA. With a tail of middling length, and pentadactylous feet, the hinder ones scaly. This is the long-tailed mole of Pennant: its length from nose to tail is four inches and six-tenths; and it is a native of North America.

RUBRA; Red Mole of Pennant. Has a short tail, tridactylous fore-feet, and tridactylous hind-feet. This is said to be a native of America.

Dr. Shaw mentions some other species, as the *T. purpurascens*, or black mole, with a gloss of purple, pentadactylous feet, and white tail, first described by Seba, and by him said to be a native of Virginia:—the *T. radiata*, or black mole, with white feet, and nose radiated with papillæ; an inhabitant of North America:—the *Sorex cristatus* of Linnæus; a variety, as Dr. Shaw says, of the *T. longicaudata*:—and the *T. fusca*, or brown mole, with white feet and tail, the fore-feet very broad; a native of North America, and supposed to be the same with the *Sorex aquaticus* of Linnæus.

TALPA, (*a mole*;) in *Surgery*, a tumour, which makes its way under the skin, as a mole under the surface of the ground. Such is said to be the derivation of the term. Talpa is often used in the language of surgery, to express an encysted tumour, which forms on the head, and contains a pap-like matter. See ATHEROMA.

TALPAR, in *Geography*, a town of Persia, in the province of Irak; 70 miles N.W. of Hamadan.

TALPARIA, in *Surgery*, an encysted tumour, filled with a pap-like matter. See TALPA.

TALPIA, in *Geography*, a town of Chinese Tartary, in the country of Hami; 28 miles N.E. of Hatantam.

TALSENGHE, a town of Hindoostan, in Vissapour; 10 miles S.W. of Vissapour.

TALSHIDE. See TALWOOD.

TALSPERG, a town of France, in the department of the Upper Rhine; 12 miles E. of Porentrui.

TALTITZ, a town of Saxony, in the Vogtland; 4 miles S. of Plauen.

TALUS, in *Anatomy*, a name formerly given to the astragalus, or that bone of the foot which is articulated to the leg. (See EXTREMITIES.) This bone in the pecora has a cubic shape; and was employed by the ancients in their famous game, ludus talorum. (See Aristotle, Hist. Anim. lib. ii. c. 1.) For the various appellations of this well-known bone in most of the European and Oriental languages, and for its form in different animals; see Th. Hyde, Historia Talorum, in vol. ii. of his Syntagma Differentationum, Oxon. 1767, 4to.

TALUS, or *Talud*, in *Architecture*, the inclination or slope of a work; as of the outside of a wall, when its thickness is diminished by degrees, as it rises in height, to make it the firmer.

TALUS, or *Talud*, in *Fortification*.—*Talus of a bastion*, or *rampart*, is the slope or diminution allowed to such a work; whether it be of earth, or stone; the better to support its weight.

The *exterior talus* of a work, is its slope on the side towards the country; which is always made as little as possible, to prevent the enemy's escalade, unless the earth be bad, and then it is absolutely necessary to allow a considerable talus for its parapet, and sometimes to support the earth with a slight wall, called a *revetement*.

The *interior talus* of a work, is its slope on the side towards the place.

This is larger than the former, and has, at the angles of the gorge, and sometimes in the middle of the curtains, ramps or sloping roads for mounting upon the terre-plain of the rampart.

TALUS, *Superior*, of the *parapet*, is a slope on the top of the parapet, that allows of the soldiers defending the covert-way with small-shot, which they could not do if it were level.

TALWOOD, **TALIATURA**, in our *Old Writers*, firewood cut and cleft into billets of a certain length: it is otherwise written *talghwood* and *talshide*. Stat. 34 & 35 Hen. VIII. c. 3. 7 Edw. VI. c. 7. 43 Eliz. c. 14.

TALYSIAN, in *Geography*, a town on the E. coast of the island of Borneo: N. lat. 1° 48'. E. long. 117° 40'.

TAM, a river of China, which runs into the Ta; 5 miles S.E. of Khi, in Pe-tche-li.

TAM, *El*, a town of Persia, in Segestan, on the Heer-mund; 25 miles E. of Zareng.

TAMA, a town of Circassia, on the Black sea; 60 miles E.N.E. of Theodosia.

TAMACH. See TAINACH.

TAMACHABAD, a town of Hindoostan, in Benares; 18 miles W. of Benares.

TAMACLIPA, a town of Mexico, in the province of Guasteca; 52 miles N. of Panuco.

TAMACUIL, a town of Mexico, in the province of Guasteca; 40 miles S. of Panuco.

TAMAHOO, a small island in the Eastern Indian sea, near the west coast of Borneo. N. lat. 0° 7'. E. long. 109° 21'.

TAMALAMEQUE, a town of South America, in the province of St. Martha, on the river Magdalena; 160 miles S. of St. Martha. N. lat. 8° 40'. W. long. 73° 56'.

TAMALAPATRA, in the *Materia Medica*, a name by which some authors have called the *folium Indicum*, or Indian leaf, used in medicine.

The tree which produces this leaf is the *laurus cassia* of Linnæus,

Linnaeus, or *cassia lignea tree*. It is a large and lofty tree, the flowers and fruit of which resemble the cinnamon-tree. Its leaves, when full grown, are ten inches or more in length; and six or eight in breadth. The flowers stand in clusters, in the manner of umbels on the tops of the branches, and are of a greenish-white colour. The fruit is of the bigness of our currant.

The ancients recommended Indian leaf as stomachic, sudorific, and cephalic. At present, it is utterly disregarded, being only kept in the shops as an ingredient in mithridate and theriaca; and is, in its greatest perfection, far inferior to the mace which our college directs as a succedaneum to it. See *CASSIA LIGNEA*.

TAMALIPAN, in *Geography*, a chain of mountains in Spanish North America, called by Alcedo, in his description of New Leon, the Grand Sierra, and a branch of which is called the Eastern Tamalipa by Alzate. This last branch extends from the deserts of Jaumape to the eastern coast of the province of Santander, where it is marked in the Spanish chart of the gulf of Mexico by the names of various peaks; while the mountain of Oreasites, visible at sea at the distance of 160 miles inland, must nearly equal Orizava in height, and appears to belong to the same branch of the grand ridge of Tamalipa.

TAMALMA, a town of Africa, in the country of Kavar; 120 miles N. of Kanem.

TAMAMES, a town of Spain, in the province of Leon; 15 miles E. of Ciudad Rodrigo.

TAMAN, an island at the mouth of the Kuban, and a principality belonging to it, and also a town on the same island, called *Phanagoria*, (which see.) This principality was anciently occupied by the Chazares; but it was wrested from them in the year 965 by the Russian combined with the Byzantine Greeks, who made themselves masters of the countries bordering on the sea of Azof in 1015, and completely overturned the Chazarian state, creating a distinct principality on the isle of Taman, to which both the Chazares and the Zichians were for a long time tributary. See *TAMUTARAKAN*.

Towards the end of the 11th century, while Russia was torn by intestine broils, the principality of Taman was lost to that empire. At length, in 1221, the Mongoles made their first attack. The Komanes were expelled or subdued, but the Ziches fought for their liberty, and could not be made to submit till the year 1277, when they were overpowered by Margu-Timur-Khan and the famous Nogay. Nevertheless, they retained some degree of independence in their woody and mountainous regions. The Ottomans indeed, in 1484, conquered the cities and forts of Taman, Temryuk, and Atschuk: but they gained no sovereignty over the Tscherkassians or Circassians. At the peace of 1774, the sultan of the Ottomans relinquished his possessions in these parts; but, contrary to treaty, held Taman and Temryuk in a state of siege, till the Crimean khan, by the aid of the Russians, drove the Ottoman garrison out of them. By the treaty of the year 1783, Russia obtained, together with the Crimea and the Eastern Nogay, the northern part of the Kuban as far as the promontory of Caucasus.

The Zichians or Tschekians, called by the Russians Yasi, are the principal inhabitants of the isle of Taman. They formerly paid a small tribute to the Crimean khan, but in all other respects are governed by their own beys. The isle Atschuk or Atschuyef is likewise inhabited by Zichians. These two tribes, which, properly speaking, are only one collateral branch of the Tscherkassians, have be-

longed to the Russian empire, as inhabitants of the Kuban, since the year 1783.

TAMAN, the strait or channel that forms a communication between the Black sea and the sea of Azof.

TAMANAH, a sea-port town of Hindoostan, on the coast of Malabar, in the country of Concan; 25 miles S. of Gheriah. N. lat. 16° 30'. E. long. 73° 15'.

TAMANDUA, in *Zoology*, a creature called in English the ant-bear; and by the Brasilians *tamanduaguacu*; and the *tamanoir* of Buffon: different species of the same genus. See *MYRMECOPHAGA*.

TAMAR, in *Geography*, a considerable river, which originates in the county of Cornwall, England, and separates that county, except for the space of a few miles, from Devonshire. It rises in a moor in the parish of Morwintow, about three miles from the North sea: passing near Whitstone, about ten miles from its source, it reaches Tamerton, which takes its name from this river; here it receives the waters of the Werrington, and about a mile and a half further its current is increased by the Attery, which runs under the walls of the town of Launceston: at Poulston-bridge it is a wide and rapid stream; a mile below Graiston-bridge it is joined by the Inney, which, rising in Altonon, passes through the parishes of Lewanick and Lezant. In the parish of Stoke-Climland, the Tamar has a high, strong, stone bridge, called by Leland "Hawtebrig," or the High bridge, now commonly Horse-bridge. The last or lowest bridge on this river is in the parish of Callstock, and was begun, according to Leland, by sir Piers Edgcombe. Five miles farther the Tamar receives the Tavy from the east, and having made a creek into the parishes of Botesfleming and Landulph on the west, becomes a spacious harbour; and after passing near the ancient borough of Saltash, is joined by the Lynher creek and river. Increasing in importance as it winds along, it next forms, between Dock and Saltash, the noble basin called the "Hamoaze," or Plymouth Harbour, where a large proportion of the British navy rides in complete security. Having made two large creeks, one called St. John's, the other Milbrook, on the west, and Stonehouse creek on the east, the Tamar, after a course of about 40 miles nearly south, falls into the sea, having mount Edgcombe for its western, and the lands of Stonehouse and St. Nicholas island for its eastern boundary, and produces the noble road for shipping named Plymouth Sound. The Tamar is one of the most considerable rivers in the west of England; its banks are richly diversified with rocks, woods, and meadows; and the scenery in various parts of its course is extremely interesting and beautiful. The views about the Cater-marther rocks, Tavistock-New-bridge, the Morwell rocks, Cotele and Pentilly, are peculiarly romantic, and can scarcely be equalled by any other river in the western part of the kingdom. (See *PLYMOUTH HARBOUR*.) Lysons's *Magna Britannia*, vol. iii. Cornwall. Beauties of England and Wales, vol. ii. Cornwall. By J. Britton and E.W. Brayley.

TAMAR, a town of Arabia, in the province of Hedsjas; 40 miles N.N.W. of Karac.

TAMAR Bay, a harbour in the straits of Magellan, E. of Cape Tamar.

TAMARA, in *Ancient Geography*, a river of Spain, which rose in the mountains W. of Lucus Augusto, and discharged itself into the sea to the W. of a small gulf, on the banks of which were Grandinurum and Acra Sestianæ. Mela calls this river Tanaris. The Tamarisci inhabited its banks.

TAMARA, a town of the isle of Albion, assigned by Ptolemy

lemy to the Damnonii or Dumnonii. Mr. Horsley thinks it was Salsath; but Mr. Camden and Mr. Baxter suppose it, more probably, to be Tamerton, which still retains its ancient name.

TAMARA, in *Geography*, a town of Morocco, on the coast of the Atlantic; 30 miles W. of Tarudant.—Also, a sea-port town on the N.W. coast of the island of Socotora, and residence of the king.

TAMARA Isles, or *Islands of Idols*, a cluster of islands near the coast of Sierra Leone. N. lat. 8° 40'.

TAMARA', in *Botany*, the Hindoo name of a very celebrated plant. (See our article **CYAMUS**, written by the late Rev. Mr. Wood.) The above name should seem to originate from the Hebrew **תמר**, *Tamar*, a Palm-tree; whence dates are called **Támara** by the Spaniards; and it may allude to the form of the seeds of the *Cyamus*, resembling dates; or to their similar use as an oriental article of food. *Támar* is also the Arabic name of the same fruit. See **TAMARINDUS**.

TAMARACA, **TAMARICA**, or *Itamaraca*, in *Geography*, a district of Brasil, in the jurisdiction of Fernambuco. It has its name from an island on the coast, near the mouth of the river Tamaraca, which constitutes the principal part of its district, though the territory thereof extends inland between 30 and 40 leagues; having Parayba on the north, Fernambuco on the south, the ocean on the east, and un subdued Indians on the west. It was reckoned one of the most ancient and flourishing captainships in Brasil; but Parayba and Fernambuco have since exceeded it. The island is parted from the main land by a very narrow channel. It is fertile and pleasant enough; producing large quantities of Brasil wood, cotton, cocoa-nuts, sugar, melons, citrons, &c. besides a good deal of timber for fuel and other purposes. It is about nine miles in length, and three in breadth, and about 22 in circuit. It has a commodious haven on the south side, with some good springs and rivulets of fresh water. The entrance into the port is by a channel of between 15 and 16 feet water, commanded by a castle, built on an eminence, and formerly taken by the Dutch: who also built Fort Orange at the mouth of the channel, which was inaccessible, by reason of the marshes surrounding it; so that the vessels that sailed down from the island were exposed to it, and they had in some measure stopped all the avenues from the Portuguese. This island, and the territory on the continent belonging to it, pay 3000 ducats to the governor of the captainship, and in it are reckoned to be about 22 sugar-mills. The French had formerly a canton or settlement on this coast, still called from them "Porto dos Francezes;" but the Portuguese obliged them to evacuate it. The capital, called "Nostra Senhora de Conceizao," or "Da Tamaraca," stands at the entrance into the river of the latter name; and near it is a small castle with a redoubt, commanding the avenues; and about four miles N. of the mouth of the river is the famous point denominated "Punta Pedro."

TAMARACA, a river of Brasil, which runs into the Atlantic, S. lat. 7° 52'.

TAMARIL, a town of Spain, in Catalonia, situated about a mile from the sea-coast; 2 miles N.E. of Tarragona.

TAMARINDUS, in *Botany*, the Tamarind-tree, is so called from *Tamar*, which is Hebrew for a Palm-tree, (and likewise the Arabic appellation of its fruit, the Date,) combined with the Latin word *Indus*, Indian. The form of the pod, and its use as an article of food, may well have given rise to the name. (See **TAMARA'**.)—Linn. Gen. 23. Schreb. 450. Willd. Sp. Pl. v. 3. 577. Mart. Mill.

Diët. v. 4. Ait. Hort. Kew. v. 4. 134. Juss. 347. Lamarck Illustr. t. 25. Gært. t. 146.—Class and order, *Triandria Monogynia*, Linn. *Monadelphia Triandria*, Schreb. Willd. Nat. Ord. *Lomentaceae*, Linn. *Leguminosae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf: tube turbinate, compressed, tapering at the base, oblique at the mouth, permanent; limb in four deep, ovate, acute, flat-tish, reflexed, coloured, deciduous segments; the upper and lower ones rather the broadest. *Cor.* Petals three, ovate, acute, concave, crenate, wavy, reflexed, the length of the calyx, inserted into the mouth of the tube; the two lateral ones rather the largest. *Stam.* Filaments three; inserted into the mouth of the calyx in the vacancy opposite to the uppermost petal, awl-shaped, as long as the corolla, connected in their lower half, curved upwards; anthers ovate, large, incumbent. There are besides seven rudiments of stamens; five of them fetaceous threads, capitate, very short, alternate with the above, connected in their lower part, two lower than the rest; and two minute bristles, proceeding from the calyx beneath the filaments, and lying upon them. *Pist.* Germen oblong, compressed, incurved, seated on a stalk, which springs from the bottom of the calyx, and is attached longitudinally to the back of its tube within, the projecting part downy along its upper edge; style awl-shaped, ascending, downy at its lower edge, rather longer than the stamens; stigma tumid, obtuse. *Peric.* Legume oblong, compressed, obtuse, with a point, swelling at the seeds, of one cell, not bursting; its coat double; the outer dry and brittle; inner membranous; a quantity of soft pulp being lodged between the two. *Seeds* few, orbicular, somewhat angular, flattened, hard, polished, with a central circumscribed disk at each side.

Ess. Ch. Calyx in four deep segments. Petals three. Barren filaments seven. Style one. Legume pulpy within.

1. *T. indica*. Tamarind-tree. Linn. Sp. Pl. 48. Willd. n. 1. Ait. n. 1. Jacq. Amer. 10. t. 10. and t. 179. f. 98. Woodv. Med. Bot. t. 166. (*Tamarindus*; Rumph. Amboin. v. 2. 90. t. 23. Ger. Em. 1607. Balam-pulli; Rheede Hort. Malab. v. 1. 39. t. 23.)—This tree, a native of Egypt, Arabia, and the East Indies, is generally preferred, rather than cultivated, in both Indies for the sake, both of its shade, and its acid, cooling, and highly grateful, as well as salutary, fruit; the pulp of which, mixed with boiled sugar, is frequently imported into Europe, and highly esteemed. The trunk is lofty, and of considerable thickness, crowned with wide-extended branches, bearing umbrageous tufts of alternate, abruptly pinnate, smooth, bright-green leaves, each composed of many pair of elliptic-oblong, sessile, entire leaflets, rather glaucous beneath. Flowers in simple clusters, terminating the short lateral branches. Petals yellow, elegantly veined with red. Fruit pendulous, like large beans. Gartner observes that the West Indian Tamarind pod is shorter than what Rheede and Rumphius represent, and has fewer seeds. Hence he distinguishes two species, which appear from history as well as observation to be mere varieties, the plant being more at home in the eastern than in the western side of the globe, though almost perfectly naturalized in the latter. It is often seen in our stoves, but seldom in blossom.—As Dr. Woodville has given an original coloured plate of this interesting plant, drawn by Mr. Sowerby from a specimen that flowered in Kew garden, and the only one of authority extant; we conceive his work, in this instance, if not in every other, might have been cited with advantage, by our friend Mr. Aiton, in the *Hortus Kewensis*.

TAMARINDUS, in *Gardening*, contains a plant of the exotic tree kind, of which the species is the tamarind-tree (*T. indica*);

dica); which grows to a very large size in the countries where it is a native: the stem being very large, and covered with a brown bark, dividing into many branches at the top, which spread wide every way; the flowers come out from the side of the branches, five, six, or more together, in loose bunches; the pods being thick and compressed; those from the West Indies from two to five inches in length, containing two, three, or four seeds; but those from the East Indies are almost twice as long, and contain five, six, and even seven seeds. The tree is a native of both the Indies, and of some other places.

Method of Culture.—This is a plant which is increased from seeds, which should be sown in the spring on a hot-bed, and when the plants are come up, each planted in a separate small pot, filled with light rich earth, plunging them into a hot-bed of tanners' bark to bring them forward, watering and shading them until they have taken root; and as the earth in the pots becomes dry, they must be watered from time to time, and have air given in proportion to the warmth of the season, and the bed in which they are placed. When the pots in which they are planted are filled with their roots, the plants should be shifted into pots of a larger size, which must be filled up with rich light earth, and again plunged into the hot-bed, giving them air as before, according to the warmth of the season; but in very hot weather, the glasses should be shaded with mats in the heat of the day, otherwise the sun will be too violent for them through the glasses; nor will the plants thrive if they are exposed to the open air, even in the warmest season; so that they must be constantly kept in the bark-stove both summer and winter, treating them in the same manner as the coffee-tree. These plants have a good effect in the stove collections.

It is the seed-pods of this tree which form and constitute the preserve called tamarinds, which is sold in the shops; and is of such a pulpy acid quality, as to be of great use in abating and quenching thirst, and in cooling and allaying excessive heat. It is brought hither from both the East and West Indies; but though the pods of the trees of the former situation are much finer and larger, the preserve from the latter is generally considered better, and of course mostly preferred.

There is nothing peculiar in the making of this sort of preserve, exactly the same methods being followed as are common in the preserving of other substances of similar kinds.

TAMARINDUS, in the *Materia Medica*. The East India tamarinds are longer than those of the West; the former containing six or seven seeds each, the latter rarely above three or four; nevertheless they seem to be the produce of the same plant: the Oriental sort is drier and darker-coloured than the Occidental, and has more pulp; the former is sometimes preserved without addition, but the latter has always an admixture of sugar.

In the West Indies, the pods are gathered in June, July, and August, when fully ripe; and the fruit, freed from the shelly fragments, is placed in layers in a cask, and boiling syrup poured over it till the cask is filled. When cool, the cask is headed for sale. When tamarinds are good, they are not in any degree musty; the seeds are hard, flat, and clean; the strings rough and entire, and a clean knife thrust into them does not receive any coating of copper. They should be preserved in closely covered jars.

We owe the knowledge of the use of tamarinds, in medicine, to the Arabians. The ancient Greeks knew nothing of them; and Serapion, Mesue, and Avicenna, are the first authors who prescribe them.

The fruit of the tamarind, which is what we use, is only

the pistil of the flower swelled into a pod; this is greenish at first, but grows brownish or reddish as it ripens; its common size is four inches in length, and one in breadth; and it is undulated on the back, and deeply notched in three or four places at the front, which is terminated by a large rib, that runs from the pedicle on which it grows, to the end of the pod, and there frequently terminates in a sort of hook.

This fruit is, properly speaking, composed of two pods, the one inclosed within the other: the outer pod is fleshy, and of the twelfth of an inch in thickness when fresh, and the inner one is as thin as a fine piece of parchment: between these two there is an intermediate space of about a quarter of an inch all the way; and this space is filled up with a very soft and pulpy substance, of a tart but very agreeable taste, which is what we use in medicine. This is blackish, and of a viscous texture, and is traversed by three large vessels, or rather bundles of vessels, one of which runs all along the back of the pod, and the two others are placed on the opposite side, and often there are several ramifications of vessels, which run off different ways from these. These vessels carry the vinous juice, which afterwards hardens into the viscous matter of the pulp; but this is not all their office, for they also convey nourishment to the seeds in the inner pod.

We use the tamarinds only in medicine; but the Africans, and the people of many of the Oriental nations, where they are common, make them into a sort of confection with sugar, which they eat as a delicacy, and which cools them in the violent heats of their climates; and at the same time keeps their bowels in a proper state of laxity. The four taste of this fruit proves, that acid particles abound greatly in it; and a chemical analysis of it gives further proof of this.

According to the analysis of Vauquelin, the pulp contains, independently of the sugar with which it is mixed, super-tartrate of potash, gum, jelly, citric acid, tartaric acid, malic acid, and a feculent matter. The acid taste chiefly depends on the citric acid, as its quantity exceeds that of the others $3xvj$ of the prepared pulp, containing $3iss$ of citric acid, but only $5ij$ of tartaric acid, $3fs$ of super-tartrate of potash, and $5fs$ of malic acid. *Annales de Chimie*, vol. v. p. 92.

The essential salt of tamarinds, as Beaumé observes, may be obtained more expeditiously, by clarifying the decoction of the tamarinds with whites of eggs, than by filtering and evaporating it to a proper consistence, and setting it to cool: the salt shoots into crystals of a brown colour, and very acid taste, but in dissolving and crystallizing them again, or barely washing them with water, they lose almost all their acidity; the acid principle of the tamarind seeming not to be truly crystallizable.

The pulp of tamarinds is an agreeable laxative acid, of common use in inflammatory and putrid disorders, for abating thirst and heat, correcting putrefaction, and loosening the belly. The dose, as a laxative, is two or three drachms; an ounce or two prove moderately cathartic. It is an useful addition with this intention to the purgative sweets, cassia and manna, in increasing their action, and rendering them less liable to produce flatulencies; the resinous cathartics are said to be somewhat weakened by it. Lewis.

This pulp is an ingredient in *confectio cassiæ*, *confectio sennæ*, and in the *infusum tamarindi cum senna*.

TAMARISCUS, in *Botany*. See *TAMARIX*.

TAMARISK PLANT, in *Agriculture*, is a plant of the large shrubby kind, which has lately, it is said, been employed in some southern situations which are much exposed to the sea air, and other effects of it, with great utility. It is capable of being readily raised and propagated by means of cuttings of the last year's growth, as they take root with-

out any difficulty, and are, of course, admirably adapted as plants for forming hedges. It is the French fort that is made up of in this way. See *QUICKSET-Hedge*.

TAMARITE, in *Geography*, a town of Spain, in Aragon; 16 miles E.S.E. of Balbastro.

TAMARIX, in *Botany*, *Tamariscus* of Tournefort, and of some, but not all, of the older botanists, is supposed to derive its name from the Tamarisci, a people who inhabited a country on the other side of the Pyrenées, where the most common species of this genus abounds. Such at least is the opinion of De Theis. Martyn says, some deduce this word from the Hebrew *Tamaris*, to wipe or cleanse; but we feel no great satisfaction in either of these etymologies.—Linn. Gen. 148. Schreb. 200. Willd. Sp. Pl. v. 1. 1498. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 338. Prodr. Fl. Græc. Sibth. v. 1. 208. Ait. Hort. Kew. v. 2. 171. Juff. 313. Lamarck Illustr. t. 213. Gært. t. 61.—Class and order, *Pentandria Trigynia*. Nat. Ord. *Succulentæ*, Linn. *Portulacæ*, Juff.

Gen. Ch. Cal. Perianth inferior, in five deep, obtuse, erect, permanent segments, half the length of the corolla. Cor. Petals five, ovate, obtuse, concave, spreading. Stam. Filaments five at least, capillary; anthers roundish. Pist. Germen pointed; style none; stigmas three, oblong, feathery, revolute. Peric. Capsule oblong, pointed, triangular, longer than the calyx, of one cell and three valves. Seeds numerous, minute, each with a stalked feathery crown.

Obf. *T. germanica* has ten stamens, five of which, alternate with the others, are external and shorter; all are connected at the base. Linn.

Ess. Ch. Calyx inferior, in five deep segments. Petals five. Capsule of one cell and three valves. Seeds with a feathery crown.

1. *T. gallica*. French Tamarisk. Linn. Sp. Pl. 386. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1318. Sm. Fl. Græc. Sibth. t. 291. unpublished. Mill. Ic. t. 262. f. 1. (*Tamariscus narbonensis*; Ger. Em. 1378. Lob. Ic. v. 2. 218. Myrica; Cæmer. Epit. 74. f. 1.)—Stamens five. Clusters lateral. Branches smooth. Leaves lanceolate, imbricated, spurred at the base.—Native of rocks and banks, or of swampy ground, especially towards the sea, in the south of Europe, and north of Africa, very abundantly. It is plentiful about the coasts of Cornwall, Hampshire, and Suffex, undoubtedly wild. This shrub appears to have been common in the English gardens, as it still is, in Gerarde's time; and yet Camden, in his life of queen Elizabeth, attributes to archbishop Grindall, who died in 1583, its being first brought into England, and made known as "exceeding good to ease the hard distemper of the spleen." (See our 7th species.) Mr. Hudson has not admitted any of this genus into his *Flora*. Dr. Sibthorp found this plant common in rather moist situations in Greece, nor can there be any doubt that it is the *μυρίκη* of Dioscorides. The Turks call it *Il Ghin*. On the eastern coast of Italy we have observed it to be the favourite food of sheep, probably on account of a saltish flavour, perceptible to our taste. This is an elegant, drooping, slender-branched shrub, with smooth and shining twigs, of a mahogany red. Leaves minute, rather fleshy, lanceolate, acute, smooth, deciduous, with a posterior spur, as in some species of *Sedum*; imbricated on the youngest shoots; scattered on the older twigs. The flowers appear in July, in copious, long, cylindrical clusters, rather than spikes, at the sides of the last year's shoots. Bractæas awl-shaped, solitary, at the base of each smooth and naked partial stalk. Calyx bell-shaped, acute, smooth. Corolla and stamens white or rose-coloured.

Willdenow's variety β we shall next describe as a distinct

species; his γ , the *T. africana* of Poirer; gathered by this traveller in Barbary, is said to have peculiarly short, thick and dense spikes, but we are not furnished with any further information on the subject.

2. *T. tomentosa*. Downy-branched Tamarisk. (*T. gallica* β ; Willd. n. 2. *T. pentandra* varietas; Pall. Ros. v. 1. p. 2. 72. t. 79. BCD.)—Stamens five. Clusters lateral. Leaves imbricated, awl-shaped, elongated, hoary and downy as well as the branches.—Found by Pallas in salt sandy deserts about the Caspian sea. He speaks of this plant as a singular very elegant variety of the preceding, about six feet high, with all its branches downy and hoary; the younger ones thicker than in the common *T. gallica*, (which he chooses to call *pentandra*), and the leaves longer, hoary, densely imbricated; all the parts being thicker and more crowded. In the clusters and flowers he observed no difference. Willdenow's suggestion, of this being probably a distinct species, is apparently well-founded.

3. *T. articulata*. Jointed-branched Tamarisk. Vahl Symb. v. 2. 48. t. 32. (*T. orientalis*; Forsk. Ægypt.-Arab. 206. *Thuja aphylla*; Linn. Sp. Pl. 1422, excluding the synonym of Shaw.)—Stamens five. Spikes lateral. Branches jointed. Leaves sheathing, abrupt, with a short spreading point.—Gathered by Forskall in Arabia. The original specimen, erroneously considered by Linnæus, for want of fructification, as a *Thuja*, appears to have been brought from Egypt, or the Levant, by Hasselquist. The plant of Shaw is *Thuja articulata*, which will hereafter be described under its proper genus. We find no certain evidence of the *Tamarix* before us being a native, as Vahl says, of the East Indies, and we imagine he confounded with it our next species. The true plant of Hasselquist and Vahl has copious slender branches, appearing when young as if jointed, each joint being crowned with a minute dotted scale-like leaf, whose annular base encircles the branch, and whose short, erect, keeled, acute point projects on one side. These leaves are permanent, enlarged, and membranous on the older branches. The flowers are described by Vahl as forming lateral spikes about the ends of the branches, each flower being sessile, accompanied by a bractea resembling the leaves, but with a widely-spreading point. Segments of the calyx roundish and obtuse. Petals the size of *T. gallica*, linear, or rather elliptical. Stamens five. Capsule with four angles, pyramidal.

4. *T. epacroides*. East Indian Tamarisk.—Stamens five. Clusters lateral and terminal. Leaves ovate, acute imbricated, clasping the stem; gibbous at the base. Bractæas awl-shaped, longer than the flowers.—Found by Kœnig growing plentifully on the banks of a river in the East Indies, which he calls *flumen Colloram maximum*. We have the same from Rottler and Roxburgh. This is unquestionably distinct from the preceding, and hitherto undescribed. The young branches have no jointed appearance, nor do the leaves surround them with an annular permanent base. The latter are succulent, of a broad triangular shape, tapering into an inflexed point; the floral ones, or bractæas, much narrower, coloured, strongly keeled. Flowers very small, on short partial stalks. Segments of the calyx broad and obtuse, fringed. Petals elliptical. Capsule scarcely above a line in length, prismatic, accompanied by the permanent filaments, which are generally rather longer. Whether the *T. chinensis* of Loureiro be this plant, his description is not sufficient to determine. He says the petals are linear.

5. *T. mucronata*. Pointed Tamarisk.—Stamens eight or ten. Spikes lateral and terminal. Leaves sheathing, abrupt, pointed. Bractæas taper-pointed, lanceolate.—The specimens of this very distinct species, in the Linnæan herbarium,

have

have no mark by which we can ascertain its native country, though we suspect them to have been sent from the East Indies. The jointed appearance of the young *branches*, and the sheathing abrupt form of the *leaves*, approach those of *T. articulata*; but the *leaves* have much more elongated and tapering points, and every part is twice the size of that species. The *foliage* moreover is much less evidently dotted. *Flowers* large, sessile, with lanceolate, membranous-edged *bractes*, whose points are longer than the calyx, and very slender. Segments of the *calyx* elliptical, obtuse, flat. *Petals* obovate. *Stamens* eight or ten, we cannot be certain which is their general number. *Capsules* prismatic, glaucous, three-quarters of an inch long. *Seed-down* long and feathery.

6. *T. songarica*. Songarian Tamarisk. "Pallas Nov. Act. Petrop. v. 10. 374. t. 10. f. 4." Willd. n. 3.—"Stamens eight or ten. Flowers axillary, somewhat spiked. Leaves fleshy, obtuse, triangular."—Gathered by Pallas, in a salt soil, on the banks of the Songari. We know nothing of this species but from Willdenow. The "triangular blunt leaves" indicate an essential difference from the last.

7. *T. germanica*. German Tamarisk. Linn. Sp. Pl. 387. Willd. n. 4. Ait. n. 2. Fl. Dan. t. 234. Mill. Ic. t. 262. f. 2. Pall. Rofs. v. 1. p. 2. 73. t. 80. (Tamariscus germanica; Ger. Em. 1378. Lob. Ic. 218. Myrica; Camer. Epit. 74. f. 2.)—Stamens ten, monadelphous. Clusters terminal. Leaves linear-lanceolate, sessile, obtuse.—Native of swamps in Germany, Siberia, Switzerland, and the mountains of Dauria and Caucasus. Common in our gardens, where it flowers in the open air from June to September. Mr. Aiton says, on Hakluyt's authority, that this was the species introduced by archbishop Grindall; see *T. gallica*. Gerarde speaks of both as prospering well in the English gardens. The present is a more upright and glaucous *shrub* than the *gallica*, as well as larger in all its parts. *Leaves* sessile, imbricated, channelled, dotted, entirely pointless, not dilated at the base. *Bractes* ovate, pointed, with membranous edges. Segments of the *calyx* ovato-lanceolate, likewise membranous at the sides. *Petals* obovate, flesh-coloured, not much longer than the calyx. *Capsule* glaucous, the size and shape of our *T. mucronata*. *Seed-down* long and finely feathery.

Pallas figures what he conceives to be an annual herbaceous variety of this species, of which, not having seen it, we do not feel ourselves competent to give an opinion.

TAMARIX, in *Gardening*, furnishes plants of the hardy, deciduous, tree and shrub kinds, of which the species that are cultivated are, the French tamarisk (*T. gallica*); and the German tamarisk (*T. germanica*).

Though the first in its native situation grows to a tree of middling size, in this climate it seldom rises more than fourteen or sixteen feet high, sending out many slender branches, most of which spread out flat, and hang downward at their ends, being rather of a shrubby nature. It is prevalent in the south of France, and in other southern countries.

But the second species is rather a shrub than a tree, having several woody stalks arising from the same root, which grow quite erect, sending out many side branches, which are also erect. It is found in many parts of Germany, &c.

Method of Culture.—All these plants may be increased either by laying down their tender shoots in autumn, or by planting cuttings in an east border, which will take root in a short time, if they are supplied with water in the spring, before they begin to shoot in dry weather; but they should not be removed until the following autumn, at which time they may be either placed in a nursery, to be trained up two or three years, or where they are designed to remain, mulch-

ing their roots, and watering them according as the season requires, until they have taken root; after which, the only culture they will require is to prune off the straggling shoots, and keep the ground clear about them.

The layer method is not only tedious, but unnecessary, as the cuttings grow readily, and the layers often will not strike at all. The cuttings should be of the last summer's shoots, and a moist border is most proper for them. In two years they will be good plants for the shrubbery, and may be planted out in almost any soil, though they like a light, moist earth best, especially the latter sort, which grows naturally in low watery situations.

Both these plants are of a rather hardy nature, and beautiful in their foliage and fine spikes of flowers. They will succeed in almost any sort of soil and situation.

They are very ornamental in the shrubbery borders, clumps, and other parts of grounds.

The former sort has likewise been lately recommended as a beneficial plant for forming quick or living hedges with, in such situations as are exposed much to the sea-air and blasts, as it has been found to stand such exposures remarkably well, where not affected by the winter frosts, of which it is rather impatient. See *QUICK Hedges*, and *TAMARISK-Plant*.

TAMARUS, in *Ancient Geography*, a river of the isle of Albion, which still retains its ancient name, being called Tamar, from Tamara, a gentle river; and its mouth is Plymouth haven.

TAMASA, or TAMASI, in *Hindoo Mythology*, is a name given to the goddess Parvati, in her black character; the word meaning blackness or darkness. The name of Tamasa, or Tamasa, was given to a dark, gloomy, astronomical character, called *Rahu*, (see that article,) and Ketu, the names severally of the dragon's head and tail, or the ascending and descending nodes of astrologers. One of the sons of Pavaka, the Hindoo fire-king, is likewise named Tamasa. (See PAVAKA.) Also one of those mythological, or historical personages, called Menus, of whom see under MENU. In the Sanscrit tongue, the root *tam* is prolific of derivations indicating properties of a dark, or gloomy, or malignant tendency.

TAMASA, in *Geography*, a river of Asia, in Mingrelia, which discharges itself into the Black sea.

TAMASIDAVA, in *Ancient Geography*, a town situated in the interior of Lower Mæsia, at some distance from the river Hierasus.

TAMASQUI, in *Geography*, a town of Mexico, in the province of Gualteca; 36 miles W.S.W. of St. Yago de los Valles.

TAMASSUS, in *Ancient Geography*, a town situated in the interior of the isle of Cyprus, W. of Ledra, on one of the streams which formed the Pedæus.

TAMATAMQUE, or *Villa de las Palmas*, in *Geography*, a town of South America, in the kingdom of Granada, on the river St. Martha; 25 miles S. of Teneriffe.

TAMATIA, in *Ornithology*, the name of a very strange bird of the Brasils. It is a species of *Bucco* in the Linnæan system by Gmelin, and the spotted-bellied barbut of Latham.

Its head is very large; its eyes large and black; its beak is two fingers breadth long, and one broad, shaped somewhat like a duck's, but pointed at the end; its upper chap is black, its under one yellow; its legs are long, and the thighs in great part naked; its toes are long; its tail is very short; its head is black, and its back and wings of a plain dusky brown; its belly is of the same brown, variegated with white.

TAMATMA,

TAMATMA, in *Geography*, a town of Africa, in the kingdom of Bornou.

TAMBA, a town of Africa, in the kingdom of Benguela; 165 miles E. of Benguela.—Also, a town of Hindoostan, in Vissapour; 20 miles S.W. of Sattarah.

TAMBA-AWRA, or **TAMBAOURA**, a town of Africa, in the kingdom of Bambouk, having in its vicinity a gold-mine; 108 miles S.E. of Gallam. N. lat. $13^{\circ} 20'$. W. long. $9^{\circ} 25'$.

TAMBAC, or **TAMBAQUA**, a mixture of gold and copper, which the people of Siam hold more beautiful, and set a greater value on, than gold itself.

Some travellers speak of it as a metal found in its peculiar mines; but upon what authority we do not know.

The abbé de Choisy, in his *Journal of Siam*, doubts whether this may not be the *electrum*, or amber of Solomon.

The ambassadors of Siam brought several works in tambac to Paris in the reign of Lewis XIV., but they were not found so beautiful as was expected. See **TOMBAC** and **GOLD-coloured Metal**.

TAMBACH, in *Geography*, a town of Germany, in the principality of Gotha; 6 miles N.E. of Smalkalden.

TAMBACUNDA, a town of Africa, in the country of Woolly; 30 miles E.N.E. of Medina.—Also, a town of Africa, in the country of Neola; 52 miles W. of Baniferile.

TAMBERCHERRY, a town of Hindoostan; 18 miles N.E. of Calicut.

TAMBILLO, a town of Peru; 56 miles N. of Oruro.

TAMBO, a town of South America, in the province of Popayan; 12 miles W. of Popayan.—Also, a town of Paraguay; 250 miles E. of Assumption.

TAMBO de Oeros, a town of Peru, in the diocese of Cusco; 136 miles W.N.W. of Cusco.

TAMBONA, a town of Hindoostan, in the country of Travancore; 40 miles N.E. of Travancore.

TAMBOOKIES, a people of the colony of the Cape of Good Hope, situated N.E. of the Kouffis, or the Kooffis, N. to the Orange river and tropic of Capricorn, are supposed by Mr. Barrow to be of Arabian extract, as they widely differ from the Hottentots and the Negroes, and are acquainted with the smelting of iron, and some other rude arts. He conceives that a belt of this race spreads across to the Atlantic. The Demaras on the Copper mountains are Kouffis; and their country is so barren and sandy, that they cannot keep cattle. The Orange river, called the Groot or Great river, seems to rise about S. lat. 30° . E. long. 28° , and passes W. by N. till it falls into the sea between the Great and Little Nemakos. It has high cataracts and inundations like the Nile. On the shores are carnellians, calcedonies, agates, and variolites. See **ORANGE-River**.

TAMBOPALLA, a town of Peru, in the diocese of Arequipa, at the mouth of the Nombre de Dios; 48 miles S. of Arequipa. S. lat. $17^{\circ} 10'$.

TAMBOS, in *Peruvian Antiquity*, buildings placed at certain distances, for the lodging of the princes of that country, in their travels through their dominions. See *M. de la Condamine*, in *Mem. de l'Acad. de Berlin*, tom. ii. p. 435; who tells us (p. 438.) that he saw several remains of these tambos, in his journey from Quito to Lima.

TAMBOV, in *Geography*, a city of Russia, on the Tzna, capital of a government, and see of a bishop; 228 miles S.E. of Moscow. N. lat. $52^{\circ} 48'$. E. long. $41^{\circ} 4'$.

TAMBOUR, in *Architecture*, a term applied to the

Corinthian and Composite capitals, as bearing some resemblance to a drum, which the French call *tambour*.

Some choose to call it the *vase*, and others *campana*, or the bell.

TAMBOUR is also used for a little box of timber work, covered with a ceiling, within the porch of certain churches; both to prevent the view of persons passing by, and to keep off the wind, &c. by means of folding-doors, &c.

TAMBOUR also denotes a round course of stone, several of which form the shaft of a column, not so high as a diameter.

TAMBOUR, in the *Arts*, is a species of embroidery.

The tambour is an instrument of a spherical form, upon which is stretched, by means of a string and buckle, or other suitable appendage, a piece of linen or thin silken stuff; which is wrought, with a needle of a particular form, and by means of silken or gold and silver threads, into leaves, flowers, or other figures.

TAMBOUR, Fr., a drum; which see.

TAMBOUR de Basque, a small drum used by the Biscayans as an accompaniment to the flageolet, or octave flute: a tabor and pipe.

TAMBOURIN, a French dance, much in favour formerly on the French stage in all the opera dances of Lulli and Rameau. The air is gay and in common time.

TAMBOURISSA, or **TAMBOURÉCISSA**, in *Botany*, Sonnerat's name for what is now called **MITHRIDATEA**; see that article. The French appellation of this tree, Bois Tambour, or Drum-tree, might be supposed to allude to the lightness and hollowness of the wood, or to its use, were not this word evidently derived from the Madagascar name of the same tree, *Ambora*.

TAMBOVSKOE, in *Geography, a government of Russia, bounded on the north by the government of Vladimir, on the east by the governments of Nizgorod, Penza, and Saratov; on the south by the government of Saratov; and on the west by the governments of Riazan and Voronez; about 200 miles in length, and from 80 to 100 in breadth. N. lat. $51^{\circ} 36'$ to $55^{\circ} 20'$. E. long. $38^{\circ} 30'$ to 48° .*

TAMBRAK, in *Ancient Geography*, a town of Asia, in Hyrcania, which, according to Polybius, was large, and had a royal palace.

TAMBRAY, in *Geography*, a town of Hindoostan, in Travancore; 60 miles N.N.W. of Anjenga.

TAMBRO, a river of Spain, which runs into the Atlantic, near Muros, in Galicia.

TAMBUCO, or **TABUCO**, a town on the east coast of the island of Celebes, situated in a bay to which it gives name. S. lat. $2^{\circ} 50'$.

TAME, a river of England, which rises near Winslow, in the county of Buckingham, and runs into the Thames at Dorchester, in Oxfordshire.—Also, a river of England, which rises near Dudley, in the county of Stafford, and runs into the Trent, about 7 miles above Burton.

TAME. See **THAME**.

TAMEGA, a river of Portugal, which runs into the Duero, 10 miles S. of Amarante.

TAMEGAN, a town of the island of Ceylon; 48 miles S. of Candi.

TAMERLANE, in *Biography*. See **TIMOUR**.

TAMETAVE, in *Geography*, a town on the E. coast of Madagascar. S. lat. $18^{\circ} 5'$. E. long. $49^{\circ} 41'$.

TAMIA, in *Ancient Geography*, a town of the isle of Albion, in the vicinity of Banatia and Alata Castra. Ptolemy assigns it to the Vacomagii.

TAMIAGUA, in *Geography*, a river of Mexico, which joins the Tufpa at its mouth.—Also, a town of Mexico, in the province of Guatemala.

TAMIEH, a town of Egypt, on a canal which forms a communication between the Nile and the Birket el Kerum; 12 miles N.E. of Fayoum.

TAMINIZ, a river of Carniola, about four miles in extent; 4 miles S.E. of Veit. It has no visible communication with any other river.

TAMINO, a river of Switzerland, which runs into the Rhine, 2 miles S. of Sargans.

TAMISRA, denoting darkness, a name of one of the hells of the Hindoos, of which they had upwards of a score. Another of the Hindoo hells is named Andha Tamisra, meaning *utter darkness*; and as these purgatories are differently placed, this is supposed to be the one situated in the bowels of the earth, and its degree of punishment an aggravation of the easier penalties inflicted in Tamisra. In the Institutes of Menu it is ordained, that “a twice-born man, who barely assaults a Brahman with an intention to hurt him, shall be whirled about for a century in the hell called Tamisra.” (Ch. iv. v. 165.) By “a twice-born man” is meant an individual of one of the three first tribes or sects, they being susceptible of regeneration by the investiture of the *zennaar*; which see. See also O'M, and *SECTS of Hindoos*.

TAMLOOK, in *Geography*, a town of Bengal; 35 miles S.W. of Calcutta.

TAMMAPUL, a town of Mexico, in the province of Guatemala; 105 miles N.W. of Panuco.

TAMMELA, a town of Sweden, in the province of Tavastland; 22 miles S.W. of Tavasthus.

TAMMERFORS, a town of Sweden, in the province of Tavastland; 36 miles N.N.W. of Tavasthus.

TAMMESBRUCK, a town of Saxony, in Thuringia, near the Unstrutt; 1 mile from Langen Salza.

TAMMOWISCHKEN, a town of Prussian Lithuania; 3 miles E. of Insterburg.

TAMNUM, in *Ancient Geography*, a town of Gallia Aquitania, upon the route from Burdigala to Augustodunum; now *Talmon*.

TAMNUS, in *Botany*, Tourn. t. 28. Juss. 43, a more correct name, perhaps, than that of *TAMUS*, used by Linnæus, which will be found in its proper place. The word has been corrupted occasionally into *Tamarus* and *Tannus*.

TAMOATA, in *Ichthyology*, the name of an American fresh-water fish, called by the Portuguese *sohido*.

It is a small oblong fish, with a flat head, somewhat like that of a frog. Its mouth is small, and from each angle of it there hangs a long single filament, by way of a beard. It has no teeth, and its eyes are extremely small. It has eight fins; two at the gills, of one finger in length, and hard and firm like horns; two on the belly, of a softer substance; and one on the middle of the back, another near the tail, and another small one opposite to it on the belly; its tail is the eighth; its whole head is covered above with a hard coat like a shell; and its body with a sort of coat of mail made up of oblong, hard, squamous bodies, dented at their edges; its colour is a sort of rusty iron-colour. It is accounted a very well-tasted fish. It lives only in fresh-water rivers; and, it is said, when the water where it is dries up, it will crawl out upon the land, and go in search of more. *Marcgrave*.

TAMOLA, in *Geography*, a town of Sweden, in the province of Tavastland; 20 miles S.W. of Tavasthus.

TAMONEA, in *Botany*, a name of Aublet's, said by De Theis to be in use among the inhabitants of Guiana, but this does not appear from any thing mentioned in the original

author. *Aubl. Guian.* 659. t. 268. *Juss.* 109. *Lamarck Illustr.* t. 542. *Verbena lappulacea* of Linnæus is referred by Jussieu to this genus. (See *VERBENA*.) We are not certain whether *Tamonea* ought to be admitted as a genus, and therefore need not stay to object to the name.

TAMONTACA, in *Geography*, a town on the west coast of the island of Mindanao. N. lat. 7° 2'. E. long. 124° 36'.

TAMOOK, a small island in the Sooloo Archipelago. N. lat. 6° 21'. E. long. 121° 58'.

TAMOS, in *Ancient Geography*, a promontory which formed mount Taurus, in the Eastern ocean.

TAMPASSOOK, in *Geography*, a town on the north-west coast of the island of Borneo. N. lat. 6° 21'. E. long. 116° 13'.

TAMPICO, a sea-port of Mexico, in the province of Guatemala, situated in the bay of the gulf of Mexico; 30 miles S.E. of Panuco. N. lat. 22° 40'. W. long. 98° 36'.

TAMPICO, a name given to a river of Spanish North America, called the *Panuco*; which see.

TAMPING a Hole, in *Mining*, is used for filling the upper part of a hole, bored in the rock for blasting with gunpowder, upon the charge of powder, with clay or stony matter rammed down very close and tight: and the clay and stone are called the tamping. This operation is called, in the North of England, stemming a hole.

TAMPION, *TOMPION*, *Tankin*, or *Tomkin*, a kind of plug or stopple, serving to close a vessel.

The word is formed from the French *tampon*, a bung, stopper, &c. Some derive it from the English *tap*.

In *Gunnery*, the tampions are wooden cylinders put into the mouth of guns, howitzers, and mortars, in travelling, to prevent the dust or wet from getting in. They are fastened round the muzzle of the guns, &c. by leathern collars. At sea they are carefully encircled with tallow or putty, to prevent the penetration of the water into the bore, by which the powder contained in the chamber might be damaged or rendered incapable of service. They are also sometimes used to put into the chambers of mortars, over the powder, when the chambers are not full. Tampions are also iron bottoms, to which the grape-shot designed for sea-service are fixed.

TAMPISCO, in *Geography*, a river of Mexico, which runs into the Pacific ocean, N. lat. 10° 38'.

TAMPOE, in *Natural History*, the name of an East Indian fruit, approaching to the figure of the mangoustan, but not near so agreeable to the taste. This fruit is very much of the size, shape, and colour of some of our common summer-apples; but its skin is very thick and tough, and it has no crown. The Indians eat it in places where better fruits are scarce, and in some places call it the mangoustan.

TAM-SAN-HOTUN, in *Geography*, a town of Chinese Tartary. N. lat. 40° 20'. E. long. 123° 48'.

TAMSHUC MOUNTAINS, mountains of Thibet; 30 miles N. of Dharmasaleh.

TAMSWEG, a town of the archbishopric of Salzburg; 12 miles W. of Muehrau.

TAMUADA, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana.

TAMUGADA, a town of Africa, in Mauritania, on the route from Lambese to Cirta Colonia.

TAMUS, in *Botany*, an old name, sometimes written *TAMNUS*, see that article, and supposed to be taken from the *Uva Taminia* of Pliny, which appears to have belonged to the plant now called Black Bryony. To this therefore the above name is at present appropriated.—*Linn. Gen.* 524. *Schreb.*

Schreb. 691. Willd. Sp. Pl. v. 4. 772. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1078. Prodr. Fl. Græc. Sibth. v. 2. 258. Ait. Hort. Kew. v. 5. 386. (Tamnus; Tourn. t. 28. Juff. 43. Lamarck Illustr. t. 817.)—Clas and order, *Diocia Hexandria*. Nat. Ord. *Sarmentaceæ*, Linn. *Aparagi*, Juff.

Gen. Ch. Male, *Cal.* Perianth in six deep, ovato-lanceolate segments, most expanded in their upper part. *Cor.* none; except the calyx be so considered, which we have recommended in a parallel case, see *SMILAX*. *Stam.* Filaments six, simple, shorter than the calyx (or corolla); anthers erect.

Female, *Cal.* (or *Cor.*) of one piece, bell-shaped, in six deep, lanceolate, spreading segments, superior, deciduous. Nectary an oblong depression in the base of each segment, at the inside. *Pist.* Germen inferior, large, ovate-oblong, smooth; style cylindrical, three-cleft, the length of the calyx (or corolla); stigmas three, reflexed, emarginate, acute. *Peric.* Berry ovate, of three cells. *Seeds* two in each cell, globose.

Ess. Ch. Male, Calyx (or rather Corolla) in six deep segments. Female, Calyx (or rather Corolla) in six deep segments. Style three-cleft. Berry inferior, of three cells. Seeds two in each cell.

1. *T. communis*. Common Black Bryony. Linn. Sp. Pl. 1458. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 91. Mill. Illustr. t. 89. (Bryonia nigra; Ger. Em. 871. Vitis nigra; Matth. Valgr. v. 2. 622. Camer. Epit. 988.)—Leaves heart-shaped, undivided.—Native of hedges, woods, and bushy places, in the more temperate parts of Europe, as well as in the Levant. It is common in England, not in Scotland, flowering in June, and laden with bunches of scarlet berries in autumn, till rotten with wet and frost. Dr. Sibthorp found this plant frequent in Greece, as well as in the isles of Crete and Cyprus. The young sprouts boiled are eaten in the latter, like aparagi, to which they are naturally allied. The fleshy perennial root is blackish externally, whence the ancient, as well as English, name. *Stems* annual, herbaceous, branched, twining round every thing in their way, and thus climbing, without tendrils, to a considerable height, till they become elegantly pendent in festoons. *Leaves* alternate, stalked, entire, acute, many-ribbed, smooth. *Stipulas* small, awl-shaped, spreading, in pairs at the base of each footstalk. *Flowers* in long, greenish, axillary clusters. *Berries* oval, the size of a large currant, bright red, insipid. The root is acrid. Its pulp scraped has formerly been used as a stimulating plaister.

2. *T. elephantipes*. Tuberous Cape Black Bryony. L'Herit. Sert. Angl. 29. Ait. n. 2. Willd. n. 2. Curt. Mag. t. 1347.—Leaves kidney-shaped, undivided. Root elevated, corky and tessellated.—Found at the Cape of Good Hope, near the town, by Mr. Masson, who sent it to Kew in 1774. A male plant flowered there, in the stove, in 1783, from whence P'Heritier caused a drawing to be made, but this plate never appeared. A female, originally imported by Mr. George Hibbert, flowered in Mr. Knight's greenhouse, and being published in the Botanical Magazine, has determined the genus, by its inferior germen, a point previously only guessed at. The singular appearance of the great fleshy root, rising out of the ground, a foot in diameter, and covered with angular, tessellated, brown knobs, more resembles the clumsy shell of some huge tortoise, than an elephant's foot. This uncouth mass sends forth in the spring a slender, twining, annual stem, about eight feet long, not unlike the last; but the leaves are very different, kidney-shaped, with strong ribs; their ends either emarginate, or abrupt with a small point. *Footstalks* tumid, or jointed, at each end.

Flowers yellowish-green. *Germen* oblong, furrowed. *Fruit* not yet observed.

3. *T. cretica*. Cretan Black Bryony. Linn. Sp. Pl. 1458. Willd. n. 3. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 958, unpublished. (Tamnus cretica, trifido folio; Tourn. Cor. 3.)—Leaves three-lobed.—Not rare in the woods and hedges of Crete and Cyprus, as well as Greece. *Sibthorp*. Miller appears to have cultivated it in 1739, but we have never met with a plant in gardens, nor is this species likely to be a popular favourite. It differs from the first chiefly in having a deep lateral sinus, on each side of the leaves, and twin clusters of flowers, one much longer than its companion. We know nothing of the fruit.—The young shoots are eaten boiled.

TAMUS, in *Gardening*, furnishes plants of the hardy, herbaceous, climbing, perennial kind, among which the species most generally grown are the common black bryony (*T. communis*); and the Cretan black bryony (*T. cretica*). The first sort has a very large tuberous root, which is blackish externally; the stems are smooth, twining about every thing in their way, and thus ascending, without the aid of tendrils, to the height of ten or twelve feet in hedges or among bushes, which their festoons of tawny leaves and red berries decorate in the autumnal season.

But the second species has a rounder root than the former; yet the stalks twine in the same manner.

Method of Culture.—All these plants are readily increased by sowing the seeds soon after they are ripe, under the shelter of bushes, where, in the spring, the plants will come up, and require no further care; or in beds to be afterwards planted out. The roots will abide many years, and sometimes fend up suckers, from which plants may be raised by setting them out in the autumn or spring where they are to remain.

The thick fleshy root of the first sort is sometimes cultivated for use in the shops.

Both the plants are useful in thickets, and in the wilderness parts of pleasure-grounds.

TAMUSIDA, in *Ancient Geography*, a town of Africa, in Mauritania Tingitana, between Banafa and Silda.

TAMUSIGA, a town of Africa, in Mauritania Tingitana, on the sea-coast, between the port of Hercules and the promontory Ufadium.

TAMUZ, in *Chronology*, the fourth month of the Jewish ecclesiastical year, answering to part of our June and July. The 17th day of this month is observed by the Jews as a fast, in memory of the destruction of Jerusalem by Nebuchadnezzar, in the 11th year of Zedekiah, before Christ 588.

TAMWORTH, in *Geography*, is a borough and market-town, situated partly in the hundred of Offlow, county of Stafford, and partly in the hundred of Hemlingford, county of Warwick, England: at the distance of 22 miles S.E. from Stafford, 27 miles N. by W. from Warwick, and 116 miles N.W. from London. It is seated near the confluence of the rivers Tame and Anker, the former of which runs through the town, and divides it into two nearly equal parts. Tamworth appears to have been of considerable note at an early period; and was the occasional residence of the Mercian kings. Offa dates a charter to the monks of Worcester from his palace here in the year 781; and several of his successors in the next century also date their grants from the same place. At that period, a ditch, forty-five feet in breadth, protected the town and royal demesne on the north, west, and east; the river serving as a defence on the south side. Of this ditch, some vestiges can still be traced, and at two angles which it forms, are two mounts, probably raised as foundations for towers. On the invasion of this kingdom

by the Danes, Tamworth was almost, or totally, destroyed. Ethelfleda, the daughter of the illustrious Alfred, is said to have rebuilt it in 913, after she had, by her prudence and valour, freed her brother's dominions from the invaders. She also erected a tower on an artificial mount, which forms the site of the present castle; and here she generally resided till her death, in 918. The castle was bestowed by William the Conqueror on Robert Marmion, whose descendants held it till 20 Edward I., when it passed by marriage to the Freville family; that of Ferrers succeeded in the reign of Henry VI.; and they were followed by the Comptons. This venerable fabric is still in a good state of preservation, as to its exterior; but the inside has suffered much from age and neglect. The rooms are numerous, but ill-suited to the liberal domestic manners of the present era; and the whole is chiefly attractive as a monument of antiquity. The town of Tamworth is large and well-built. It was incorporated by queen Elizabeth on a scale peculiarly liberal: the corporation consists of two bailiffs, a recorder, high steward, under steward, a town-clerk, and twenty-four principal burghesses: one of the bailiffs is chosen from each county. Tamworth has sent two representatives to parliament ever since the year 1563. The right of election is in the inhabitants paying scot and lot: and the members are returned jointly by the sheriffs of Warwickshire and Staffordshire. The church is a spacious edifice. The most ancient portion exhibits two round-headed arches, embellished with zig-zag mouldings: whence it seems probable that the original edifice was constructed soon after the Conquest. The church was rendered collegiate by the Marmion family at an early period for a dean and six prebendaries; with several lay prebendaries, which are still attached to the church. The college was granted by queen Elizabeth in 1581 to Edward Downing and Peter Ashton. An hospital was established in this town by Philip Marmion in the 15th year of Edward I. On its site another was founded and endowed by Mr. Guy, to whom the borough of Southwark is indebted for the noble hospital which bears his name. A grammar-school, founded by queen Elizabeth, is still well supported. Here are some manufactures, the chief of which is that of superfine woollen cloths: but this trade, though still respectable, has much decreased. The printing of calicoes, the tanneries, the manufacture of flax, and the spinning of yarn, are branches of business which have considerably advanced. A weekly market, under queen Elizabeth's charter, is held on Saturdays: and three fairs annually. In the population return of the year 1811, the Staffordshire division of Tamworth was stated to contain 279 houses, and 1327 inhabitants; the Warwickshire division 325 houses, and 1666 inhabitants: making a total of 2903 persons, occupying 604 houses.

About four miles south-east of Tamworth is Pooley-Hall, the seat of the honourable colonel Finch. The lands attached to this residence formed part of the possessions of the Marmions; and after several intermediate transmissions, came to the family of Cokaine, in the latter part of the 14th century. It is ascertained that sir John Cokaine resided at Pooley in the reign of Henry IV., and his descendants, for many generations, made it their principal seat. The present mansion was erected by sir Thomas Cokaine, temp. Henry VIII., and is a fine but irregular building, varying in character between the embattled style of the previous troubled and suspicious ages, and the open amplitude of construction then first growing into practice.—*Beauties of England and Wales*, vol. xiii. Staffordshire, and vol. xv. Warwickshire, by J. N. Brewer.

TAMWORTH, a town of America, in New Hamp-

shire; 56 miles N. of Portsmouth; containing 1134 inhabitants.

TAMYRACA, in *Ancient Geography*, a town of European Sarmatia, near the Cærcinite gulf.

TAN, the bark of the oak, chopped, and ground by a tanning-mill into a coarse powder; to be used in the tanning or dressing of skins. See TANNIN.

New tan is the most esteemed; when old and stale, it loses a great deal of its effect, which consists in condensing or closing the pores of the skins; so that the longer the skins are kept in tan, the greater strength and firmness they acquire.

This bark, which is more abundant in the gummy resinous part than any of our common indigenous astringents, and which, on account of its astringent, gummy, resinous property, serves both to preserve leather from rotting, and to render it impervious to water, is preferred to all other substances for the purpose of tanning. It is used either in the way of infusion, which is called ooze; or the dry powder is strewed between layers of hides and skins, when these are laid away in the tan-pits. The ooze is made by macerating the bark in common water, in a particular set of holes or pits, which, by way of distinction from the other holes in the tanyard, are called latches. See TANNING.

Every part of the oak-tree, of what age or growth soever, is fit for the tanner's use, and all oaken coppice-wood, of any size or age, being cut and procured in barking-time, will tan all sorts of leather; at least, as well as the bark alone. When this material is got at the proper season, it must be very well dried in the sun, more than the bark alone; thence it is to be cut up, and preserved in a covered place for use.

When it is to be used, the greater wood must be first cleft small, to fit it for the beating and cutting-engine; and the smaller must be put into the engine as it is: which done, it must be again dried upon a kiln, and after that, ground in the same manner that the tanners grind their bark. Such wood as is to be used presently after it is gotten, will require the better and the more drying upon the kiln; and if this is omitted, it will blacken and spoil all the leather it is used about. Where oak is scarce, black-thorn, or sloe-tree, will tolerably well supply its place; and where that is not to be had in sufficient plenty, the white-thorn will do. *Phil. Tran.* N^o 108.

Birch also, being ordered in the same manner with oak, is fit for some uses in tanning, particularly it does very well for tanning of shoe-sole leather. All these ingredients will tan much better than bark alone; and that with much less charge; so that this discovery may very well save the felling of trees when the bark is wanted, at a season when the sap is up, which, when it is done, causes the outside of the trees to rot and grow worm-eaten; whereas, if the trees had been felled in winter, when the sap is down, they would have been almost all heart, as the people express it, and not subject to worms. This manner of using the wood with the bark, in tanning, will also increase the value of underwoods very considerably. *Phil. Tranf.* N^o 105.

The engine necessary for cutting the wood consists of a long square wooden block, and some pieces of iron to be fastened on and used about it, viz. a hammer, an anvil, an iron holding the wood to be bruised and cut, and a knife to cut it. The whole is a very simple and cheap machine, and is described at large, and figured in the above-mentioned number of the *Philosophical Transactions*.

By M. de Buffon's experiments upon different skins, it was found that a decoction of young oak-wood succeeded perfectly well in tanning sheep and calves' skins, but did

not do equally well for ox, and the other harder skins. This, however, he imagines, might be only for want of knowing the best method of using the wood. And certainly these trials deserve to be farther prosecuted; since the small branches of the oak, which are of little value, might be thus made to supply the place of a much dearer commodity, the bark; and as in many trees the bark of the young branches is found to be of greatly more virtue than that of the larger branches, or the trunk, the use of these small boughs, bark and all, might very probably be found to answer to all the effects of the bark of the larger kind alone. *Memoirs Acad. Scienc. Par. 1736.*

The Society of Arts, &c. granted a premium of 100*l.* in the year 1765, for the discovery of a method of tanning with oaken saw-dust; but the acquisition has not hitherto had its desired effect; though it is said that the use of oaken saw-dust has been advantageously adopted in Germany. *Doffie's Mem. of Agr. vol. i. p. 227.*

We are told, in *Phil. Trans. N^o 36*, that the operation of tanning is performed, on leather, better in the West Indies than in England. They use three sorts of bark, the man-grove-bark, the olive-bark, and another; and the whole business is so soon done, that a hide delivered to them, is in six weeks ready to be worked into shoes, though they bestow less labour than we do.

Mr. Albert Gefner, first physician to the duke of Wirtemberg, having made some experiments on the dust of heath, dried in an oven, and afterwards pulverized, as a substitute to that of oak-bark in tanning, found that the leather prepared by this method was very good; but he observes, that the operation is much more tedious. (*Hist. R. A. S. Paris, for 1756.*) Others have proposed a trial of the small branches of heath, and the leaves of oak.

TAN, in *Gardening*, a substance of the oak-bark, or other similar kinds; after it has been ground and soaked in the ooze of the tanners' vats, and properly dried, is used for the purpose of making hot-beds, for forcing many sorts of exotic plants that require a durable steady heat.

It has not been of very long use in England, and was brought to us from Holland in the reign of king William, and then used for the raising of orange-trees; but after this period it became disused; and it is of a much later date, *viz.* about the year 1719, that it has been brought into use again for the raising of the pine-apple, since which time it is become generally used, wherever it is to be had, for all the purposes of the hot-bed, in raising tender exotic plants.

Refuse tan, made up into cakes, serves as fuel, in circumstances where a gentle and continued fire is advantageous. See *BARK-Bed*, *HOT-Bed*, *HOT-House*, and *STOVE*.

TAN, *Flower of*, is a name given by the people employed in the tanning-trade, to a yellow substance, often found upon old tan, or oak-bark broken to pieces, which has been used as tan, and is of no farther service.

The name, however, is very improper; and though every body conversant in tan-yards must have seen the thing, yet it has always passed as an effluence of the bark, till the curious Mr. Marchand inquired more accurately into its nature, and found it to be a plant of itself, wholly different from the matter of the tan; and to which the bark, which had been often wetted and dried again, served as a proper matrix. He found it to be more nearly allied to the sponge, than to any other genus of plants, and therefore named it *spongia fugax mollis flavia & amana in pulvere coriario nascens*, soft, beautiful, yellow-fading sponge, growing on tanners' bark.

It makes its appearance most frequently in the summer-

months, and is then seen in small tufts of a beautiful yellow colour, on different parts of the old heaps of bark. It appears at first in form of a thin yellow scum, and is of a sort of jelly-like structure; but it every day grows larger and thicker, till it stands above half an inch out from the surface of the bark. As it grows, its surface becomes more and more cavernous and spongy, the pores or holes being of different diameters, and the interstitial matter forming a sort of net-work more or less regular, and often interrupted by irregular prominences in several parts; and, in fine, when the growth is complete, the whole more resembles a sponge than any vegetable substance, and is of a deep yellow colour, and considerably thick and tough consistence; there are no roots to be discovered issuing from it; its smell is like that of rotten wood, and its taste is somewhat styptic. It always appears in the warm months, and always upon such old tan as has begun to ferment, and is in the state in which our gardeners use it for hot-beds. If it happens to stand exposed to the fourth sun, it is but of short duration; but if it be in a sheltered place, it will last a considerable time, and often spread itself to a great extent, and make a very beautiful figure for many weeks. *Mem. Acad. Par. 1727.*

TAN-Bed, in *Gardening*. See *BARK-Bed*.

TAN-Pit. See *BARK-Pit*.

TAN-Spud, in *Rural Economy*, the name usually given to a particular sort of tool used for peeling of the bark from oak, and some other trees, in certain districts; but in others they employ several different implements for effecting this purpose.

TAN-Stove. See *HOT-House* and *STOVE*.

TANA, in *Geography*, the most considerable river in Finmark.

TANACETUM, in *Botany*, Tanfy, a barbarous Latin word, of which, like *Osmunda*, it is scarcely possible, as Linnæus remarks, *Phil. Bot. 160*, to determine the meaning, or from what language it is derived. Of *OSMUNDA* we have attempted an explanation. (See that article.) De Theis cites Linnæus and Dodonæus as deducing *Tanacetum* from *Athanasia*; but we find no such etymology given by them, though several writers speak of these words as synonymous, and some lexicographers give that explanation. *Αθανασία*, as expressing an un fading, or everlasting, flower, is little applicable to our Tanfy.—*Linn. Gen. 417. Schreb. 549. Willd. Sp. Pl. v. 3. 1809. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 862. Prodr. Fl. Græc. Sibth. v. 2. 167. Ait. Hort. Kew. v. 5. 1. Pursh 522. Juss. 184. Tourn. t. 261. Lamarck Illustr. t. 696. Gært. t. 165.—Class and order, Syngenesia Polygamia-superflua. Nat. Ord. Compositæ discoides, Linn. Corymbifera, Juss.*

Gen. Ch. *Common Calyx* hemispherical, imbricated, with acute compact scales. *Cor.* compound, tubular, convex. Florets of the disk numerous, funnel-shaped, with five reflexed segments in the limb, all perfect: those of the radius few, small, three-cleft, most deeply divided at their inner side. *Stam.* in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in the perfect florets, Germen oblong, small; style thread-shaped, the length of the stamens; stigma in two revolute segments: in the female ones; Germen oblong; style simple; stigmas two, reflexed. *Peric.* none, except the unchanged calyx. *Seeds* solitary, oblong, crowned with more or less of a slight margin. *Recept.* convex, naked.

Obf. Sometimes the radius is wanting, all the florets being, in that case, perfect. The seeds of some species are said to want the crown.

TANACETUM.

Eff. Ch. Receptacle naked. Seeds crowned with a border. Calyx imbricated, hemispherical. Florets of the radius three-cleft, obfolete, sometimes wanting.

1. *T. vestitum*. Leafy Cape Tanfy. Thunb. Prodr. 147. Willd. n. 1.—“Leaves slender, triangular, imbricated. Panicle terminal.”—Native of the Cape of Good Hope. *Thunberg*.

2. *T. longifolium*. Long-leaved Cape Tanfy. Thunb. Prodr. 147. Willd. n. 2.—“Leaves linear-thread-shaped. Cluster terminal, level-topped.”—Found in the same country.

3. *T. linifolium*. Flax-leaved Cape Tanfy. Thunb. Prodr. 147. Willd. n. 3. Ait. n. 1. (*Athanasia linifolia*; Linn. Suppl. 361.)—Leaves linear-lanceolate, channelled, taper-pointed. Cluster terminal, simple, corymbose.—Native of the Cape of Good Hope. Sent to Kew by Mr. Masson in 1774. A green-house shrub, flowering in August. The stem is simple, round, and smooth, clothed with alternate, simple, linear or awl-shaped leaves. Flowers ovate, smooth, yellow. The length of the leaves is variable.

4. *T. axillare*. Axillary Cape Tanfy. Thunb. Prodr. 147. Willd. n. 4.—“Leaves linear-thread-shaped, combined at the base. Flowers axillary, sessile.”—Gathered by Thunberg at the Cape.

5. *T. uliginosum*. Marsh Levant Tanfy. Prodr. Fl. Græc. n. 2029. Fl. Græc. t. 855, unpublished. (*Santolina vermiculata cretica*; Tourn. Inst. 461?)—Leaves linear; the lower ones with one lateral tooth. Stalks solitary, terminal, single-flowered.—Gathered by Dr. Sibthorp in boggy parts of the isle of Cyprus, intermixed with *Juncus bufonius*. The root is annual, simple, tapering, with many whitish fibres. Stems several, ascending, branched from the bottom, three or four inches high, round, smooth, leafy. Leaves alternate, sessile, an inch long, acute, channelled, smooth, mostly entire; a few of the lower ones only dilated slightly at the end, and furnished with a lateral tooth. Flowers terminal, solitary, yellow, hemispherical, each on a simple, naked, smooth, erect stalk, two or three inches in length, purplish at the top. Seed, according to Mr. Bauer's drawing, crowned with an oblong tubular scale, split on one side.

6. *T. suffruticosum*. Shrubby Cape Tanfy. Linn. Sp. Pl. 1183. Willd. n. 5. Ait. n. 2. Thunb. Prodr. 146. (*T. africanum fruticosum multiflorum, foliis tanaceti vulgaris decuplo minoribus*; Comm. Hort. v. 2. 199. t. 100.)—Leaves in many pinnate, subdivided, acute, somewhat downy segments. Stem shrubby. Flowers corymbose, level-topped.—Native of the Cape of Good Hope, from whence the Dutch obtained seeds above a century ago, and it probably soon found its way into our more curious green-houses. The plant has little to attract general admiration, though the leaves are delicately divided, and the leafy branches are terminated by abundance of little golden corymbose flowers, whose calyx is membranous and shining.

7. *T. sibiricum*. Long-leaved Siberian Tanfy. Linn. Sp. Pl. 1183. Willd. n. 6. (T. n. 116; Gmel. Sib. v. 2. 134. t. 65. f. 2.)—Leaves pinnate; leaflets linear-thread-shaped, entire; undivided or three-cleft. Flowers corymbose, level-topped. Calyx-scales nearly orbicular, smooth.—Gathered by Steller, in dry mountainous parts of Siberia, beyond the lake Baical, flowering in June and July. The root is brown, rather thick, with many fibres running deep into the ground, and apparently perennial. Stems about eighteen inches high, erect, round, striated, smooth, somewhat leafy; branched and corymbose at the top. Leaves acute, not unlike those of Southernwood, but smooth; the

lower ones on long stalks; the uppermost sessile, at the base of each branch. Flowers bright yellow, partly drooping, encompassed by the white membranous edges of the green orbicular scales of the calyx.

8. *T. argenteum*. Silvery Armenian Tanfy. Willd. n. 7. “Ejusd. Achill. 51. t. 2. f. 4.” (*Achillea argentea*; Lamarck Dict. v. 1. 29. *Parmica orientalis, foliis argenteis conjugatis*; Tourn. Cor. 38.)—“Leaves pinnate, clothed with silky down; leaflets lanceolate, slightly toothed at the extremity. Corymb terminal.”—Gathered by Tournefort in Armenia. This is said to bear some resemblance to the *Achillea Clavenna*. The stem is about a foot high, simple, channelled, covered, like the rest of the herb, with silky down. Leaves alternate, stalked, with linear or lanceolate leaflets, most of which, especially in the radical leaves, have two or three teeth towards the end. Flowers probably white. Receptacle constantly naked. Calyx membranous at the edge of the inner scales. *Lamarck; Willdenow*.

9. *T. angulatum*. Dropwort-leaved Tanfy. Willd. n. 8. “Ejusd. Achill. 52. t. 2. f. 3.” (*Achillea filipendulina*; Lamarck Dict. v. 1. 27. *Parmica orientalis, tanaceti folio et facie, flore minimo*; Tourn. Cor. 38.)—Leaves pinnatifid; segments lanceolate, ferrated. Corymb dense. Calyx angular.—Gathered in the Levant by Tournefort. Stem a foot, or rather more, in height, channelled, almost smooth, but sparingly leafy in the upper part. Lower leaves two or three inches long, deeply pinnatifid, green, and smooth; upper about half as long. Flowers yellow, in a small dense corymbus. Florets of the radius scarcely more than two or three, very short. Receptacle elevated, furnished with a very few scales at the margin. *Willd. Lamarck*.

10. *T. microphyllum*. Small-leaved Siberian Tanfy. (*Achillea* n. 164; Gmel. Sib. v. 2. 198. t. 83. f. 2. *Parmica millefolii folio tomentoso, flore luteo*; Gerb. MSS. in Herb. Linn.)—Leaves pinnate; leaflets bipinnatifid, hairy, obtuse. Flower-stalks corymbose, hairy. Calyx smooth.—Gathered by Gerber, in deserts, on both sides of the river Don, near upper Kundruchewa. He remarked that the receptacle is devoid of scales, which induces us to introduce this plant here, though referred to *Achillea* by Gmelin. Linnæus has passed it over. The root is woody and apparently perennial. Stem a span high, more or less branched, leafy, angular, and downy. Leaves stalked, hairy, finely subdivided and notched. Flowers yellow, rather hemispherical than cylindrical. Calyx-scales oblong, ending in a suddenly dilated white membrane; the base of the outward ones only occasionally hairy, or fringed. Florets of the radius very short, three-toothed.

11. *T. incanum*. Hoary Oriental Tanfy. Linn. Sp. Pl. 1183. Willd. n. 9. (*Abinthium orientale incanum tenuifolium, floribus luteis in capitulum congestis et fursum spectantibus*; Tourn. Cor. 34.)—Leaves pinnate, hoary; leaflets crowded, in deep finger-like segments. Corymbs dense, compound, somewhat paniced.—Native of the Levant. The stem is said by Linnæus to be simple, leafy, and very short. We have seen neither specimen nor figure.

12. *T. cotuloides*. May-weed Cape Tanfy. Linn. Mant. 282. Willd. n. 10.—Leaves deeply pinnatifid, pointed, hairy, dotted. Stem much branched. Flowers somewhat paniced. Calyx-scales elliptical, nearly equal.—Native of the Cape of Good Hope. Root somewhat woody, with many fibres; Linnæus judged it to be annual. Stem about a span high, copiously branched, round; branches ascending, leafy, hairy. Leaves numerous, scattered, stalked, hardly an inch long, in seven or nine deep, acute, entire segments, clothed, on the lower side at least, with very long straight

TANACETUM.

straight loose hairs. *Flower-stalks* paniced, hairy, leafy, somewhat corymbose. *Flowers* small, hemispherical, rather convex, yellow, with few or no radiant florets. *Calyx-scales* acute, rather lax, roughish, with thin pale edges.

13. *T. orientale*. Silky-leaved Oriental Tanfy. Willd. n. 11. (*Abfinthium orientale incanum, capillaceo folio, floribus in capitulum congestis*; Tourn. Cor. 34.)—"Leaves silky and hoary; the radical ones pinnate; leaflets in three deep, linear-thread-shaped, acute segments; stem-leaves in three deep, lanceolate segments. Panicle densely corymbose."—Native of Armenia. *Root* perennial. *Leaves* of the root and barren stems about three-quarters of an inch long, on still longer *footstalks*; those of the flowering stem broader, their segments flat, occasionally divided. *Panicle* corymbose, terminal. *Flowers* sessile, in round heads, upon crowded stalks. *Calyx* downy. *Receptacle* naked. Willd.

14. *T. annuum*. Annual Tanfy. Linn. Sp. Pl. 1184. Willd. n. 12. Ait. n. 3. (*Santolina corymbis simplicibus fastigiatis, foliis linearibus confertis*; Mill. Ic. t. 227. f. 1. Elichryson; Cluf. Hist. v. 1. 326. Elyochryson, five Coma aurea; Ger. Em. 645.)—Radical leaves doubly pinnate; those of the stem deeply pinnatifid, downy; their segments sharp-pointed. *Corymbs* level-topped. *Calyx-scales* oblong, hairy.—Native of Spain and Italy. Very soon introduced into our gardens, where it proves a hardy annual, flowering in July and August. The *stem* is two or three feet high, round, furrowed, much branched, clothed with innumerable small crowded pinnatifid *leaves*, of a rather hoary green. *Flowers* yellow, in terminal flat corymbs; the scales of their *calyx* unequal, imbricated, keeled, hairy, tipped with a rounded membrane.

15. *T. obtusum*. Blunt-leaved Cape Tanfy. Thunb. Prodr. 147. Willd. n. 13.—"Leaves doubly pinnate, smooth; leaflets linear, obtuse. Heads of flowers solitary, smooth."—Found by Thunberg at the Cape of Good Hope.

16. *T. grandiflorum*. Large-flowered Cape Tanfy. Thunb. Prodr. 147. Willd. n. 14.—"Leaves doubly pinnate, villous; leaflets linear, acute. Heads of flowers solitary, downy."—From the same country.—We have not seen either of the two last species. Willdenow understands Thunberg's expression, *capitulis solitariis*, as meaning *floribus solitariis*; but the supposition of so great an inaccuracy is scarcely warrantable. We therefore preserve the original sense; whether it be accurate or not must remain with the author.

17. *T. multiflorum*. Many-flowered Cape Tanfy. Thunb. Prodr. 147. Willd. n. 16.—"Leaves doubly pinnate, villous; leaflets acute. Panicles compound, level-topped."—Found by Thunberg at the Cape.

18. *T. myriophyllum*. Millfoil Tanfy. Willd. n. 17. "Ejusd. Achill. 50." (*Achillea bipinnata*; Linn. Sp. Pl. 1265. *Parmica orientalis incana, foliis pennatis, semisofculis florum vix conspicuis*; Tourn. Cor. 38.)—Leaves doubly pinnate, downy; leaflets ovate; those of the stem toothed; of the radical leaves entire.—Native of the Levant. Only to be seen perhaps in Tournefort's herbarium, or in collections extracted from thence.

19. *T. vulgare*. Common Tanfy. Linn. Sp. Pl. 1184. Willd. n. 18. Ait. n. 4. Fl. Brit. n. 1. Engl. Bot. t. 1229. Woodv. Med. Bot. t. 115. Fl. Dan. t. 871. (*Tanacetum*; Ger. Em. 650. Matth. Valgr. v. 2. 259. Camer. Epit. 650.)—*T. crispum anglicum*; Ger. Em. 650.—Leaves doubly pinnatifid, sharply serrated, naked.—Native of banks, hedges, and borders of fields, in most parts of the middle of Europe; very frequent in England,

flowering in July and August. *Root* perennial, creeping. *Herb* two feet high, leafy, dark green, with a strong balsamic scent, and bitter taste. It was formerly more used than at present to give a flavour, as well as a green colour, to a rich kind of pudding. The *leaves* are copious, sessile, a span long, sometimes a little hairy underneath; clasping the stem with their dilated base. *Flowers* composing a large, flattish, terminal, golden *corymbus*. The *radius* is scarcely remarkable but in hot seasons, though its rudiments may generally be detected. The curled-leaved variety is esteemed most aromatic and wholesome.

Willdenow's fifteenth species, *T. monanthos*, Linn. Mant. 111, having a scaly receptacle, is referred to *SANTOLINA*, (see that article,) in the Prodr. Fl. Græca, by the specific name of *S. rigida*. This is a depressed annual plant, with doubly-pinnatifid pointless *leaves*; single-flowered ascending hairy *stalks*; and a hairy *calyx*, whose scales are nearly equal. The *flowers* are yellow. This is a native of Cyprus, and very nearly akin to *S. anthemoides*, Linn. Sp. Pl. 1180; whose *calyx* is imbricated on all sides, and its *leaves* have brittle-pointed segments.

TANACETUM, in *Gardening*, furnishes plants of the herbaceous and shrubby perennial kinds, among which the species most commonly cultivated are, the common tanfy (*T. vulgare*); the annual tanfy (*T. annuum*); the costmary tanfy (*T. balsamita*); the Siberian tanfy (*T. fibiricum*); the shrubby tanfy (*T. suffruticosum*); and the fan-leaved tanfy (*T. flabelliforme*).

In the first sort there are varieties with curled leaves, called double tanfy; with variegated leaves; and with larger leaves, which have little scent.

Method of Culture.—All the different herbaceous species are increased by parting the roots, and by seed.

In the first mode the business is effected by slipping or dividing the roots in autumn or winter, when the stalks are decayed; or early in spring, before new stalks shoot forth; planting the slips at once where they are to remain; those for the kitchen-garden, as the common tanfy, &c. in any bed or border a foot and a half asunder; and those intended for variety in the pleasure-ground, singly here and there, at suitable distances, to effect a proper diversity.

The seed sowed in autumn should be sown in the spring following, in beds of light earth, broad-cast and raked in, when the plants will soon come up, and in July be fit to prick out in beds, in rows a foot asunder; some to remain, and others to be planted out in autumn where they are to grow.

All the shrubby sorts are easily increased by cuttings of the branches, which should be planted any time in spring and summer, choosing the young and most robust shoots, which should be cut off in proper lengths, and if early in spring, &c. be planted in pots of good earth, several in each, plunging them in a hot-bed, where they will be rooted, and fit for potting off separately in six weeks; or if in summer, the young shoots may be planted in the full ground, in a shady border, or where they may be shaded with mats from the sun; or in pots, and placed in the shade, or under a garden-frame, &c.: in all of which methods, giving plenty of water, they will readily take root; but those in the hot-bed will be forwardest: they, however, will all be well rooted the same season, and should then be transplanted into separate pots, and managed as other shrubby greenhouse plants. See *GREEN-HOUSE Plants*.

Most of the former sorts require to be afterwards kept free from weeds, cutting down the decayed stalks annually in autumn; and as the roots increase fast into large bunches, spreading

spreading widely round, they should be cut in, or be slipped occasionally, otherwise they are apt to overrun the ground; and to have the ground dug between the plants annually.

All the latter sorts are somewhat tender, but only require shelter from frost, being kept in pots, and deposited among the greenhouse plants, and treated as other shrubby exotics of that collection. They effect a very agreeable variety at all times of the year, but particularly in summer and autumn, when in flower.

The common tanfy has been long cultivated in the garden as a culinary and medicinal herb; the leaves being used occasionally while young and tender, in fallads during the spring season, as well as for making cakes, puddings, and many other similar articles. The powder of the dried leaves, the seeds, and the flowers, have also been sometimes employed as a remedy against worms.

The curled and variegated sorts or varieties are principally made use of for ornamental purposes.

The earl of Dundonald has proposed the cultivation of the tanacetum, or tanfy, for the production of potash, asserting that it will yield more of this alkali than can be procured from an equal weight of any other vegetable.

TANACETUM, in the *Materia Medica*. See TANSY.

TANADASSA, in *Ancient Geography*, a town of Africa Propria, on the route from the Grand Leptis to Tacapæ.

TANÆCIUM, in *Botany*, so named by Dr. Swartz, on account of its very long climbing stem and branches, from *tanæci*, stretched out, or rather having an elongated point.—Swartz Prodr. 91. Ind. Occ. 1049. t. 20. Schreb. Gen. 412. 834. Willd. Sp. Pl. v. 3. 312. Mart. Mill. Dict. v. 4.—Class and order, *Didymia Angiospermia*. Nat. Ord. *Luride*, or perhaps *Putamineæ*, Linn. Swartz. Akin to *Solanaceæ*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, tubular, undivided, abrupt, nearly or quite entire. Cor. of one petal, long; tube cylindrical, dilated upwards, limb spreading, in five, somewhat unequal, or two-lipped, deep segments. Stam. Filaments four, shorter than the tube of the corolla, two of them rather shorter than the rest, with an intermediate rudiment of a fifth; anthers two-lobed. Pist. Germen superior, roundish, seated on an annular receptacle; style simple, about the length of the stamens; stigma two thick spreading lobes. Peric. Berry very large, globose or oblong, on a short stalk, of two cells, with a hard coat. Seeds small, numerous, oblong, angular, inserted into a central globose receptacle.

Ess. Ch. Calyx cylindrical, undivided, abrupt. Corolla tubular, rather unequal, five-cleft. Rudiment of a fifth stamen. Berry coated, of two cells, with many seeds.

Obs. This genus surely belongs to the *Luride* of Linnæus, and is considerably akin to another genus of Swartz's, the *SOLANDRA*, see that article, though he does not appear to advert to this affinity.

1. *T. parasiticum*. Simple-leaved Tanæcium. Willd. n. 1. Swartz Ind. Occ. 1053. Jacq. Hort. Schoenbr. v. 1. 61. t. 115.—Leaves simple, ovate, coriaceous. Stem shrubby, climbing parasitically.—Native of woods in the western part of Jamaica. Stem when young closely attached by fibrous radicles to the trunks of trees, round, with a grey rugged bark; when full-grown, it often decays below, supporting itself altogether parasitically, and sending out round, spreading, smooth, leafy branches. Leaves opposite, on short thick stalks, five or six inches long, entire, acute, scarcely pointed, smooth, of a fine shining green, with one rib, and many oblique veins. Flower-stalks axillary, short, each bearing about four elegant

drooping flowers, about an inch and a half long. Calyx swelling, purplish-red, contracted at the mouth, quite entire. Corolla with a pale yellowish tube, and crimson, spreading or reflexed, border, whose segments are rounded, and nearly uniform, the lowermost only a little the largest, and folding over the mouth like a lid, before the flower expands. Berry globose, as big as a small apple, with a brown brittle coat. Swartz once found a fruit with three cells.

2. *T. Jaroba*. Three-leaved Tanæcium. Willd. n. 2. Swartz Ind. Occ. 1050. t. 20. f. 1. (Jaroba; Marcgr. Brasil. 25. Pis. Brasil. 173. Cucurbitifera fruticosa trifolia scandens; Sloane Jam. v. 2. 175.)—Lower leaves ternate; upper in pairs, with an intermediate terminal tendril. Stem climbing.—Native of woods, on the banks of rivers, in the western part of Jamaica. Swartz found it in flower in February, climbing to the top of a tree of the *Bignonia leucoxydon*. The shrubby stem mounts to a great height, where it has an opportunity of support, sending out long, pendulous, round, slightly striated, herbaceous branches. Leaves opposite, stalked; the lower ones with three ovate, pointed, entire, ribbed, smooth, scarcely coriaceous, leaflets, each half a foot long; upper of two rather smaller ones, with a slender rigid tendril in the place of a third leaflet, by which the branches are supported on those of neighbouring trees. Clusters axillary, of few flowers, with thick, round, opposite stalks. Flowers white, short-lived. Calyx gibbous at the base; sometimes very minutely five-toothed at the margin. Corolla funnel-shaped; its tube six or seven inches long, swelling at the top, downy both within and without; segments of the limb ovate, wavy or plaited, about three-quarters of an inch in length, all nearly equal, though the two uppermost arc, as in the former species, less deeply separated. Berry very large, a foot long, oval, pendulous, smooth, brittle when ripe. Seeds large, broad, compressed, lying closely over each other. The Portuguese call this plant *Casca amargosa*, on account of its bitterness.

3. *T. pinnatum*. Pinnate Tanæcium. Willd. n. 3. (Crescentia pinnata; Jacq. Coll. v. 3. 203. t. 18.)—Leaves pinnate. Stem arboreous, erect.—Native of Mozambique, where it is called *Kigelikeya*, and from whence it was carried to the isles of Mauritius or Bourbon, and thus got into the imperial gardens at Schoenbrun, being accompanied by a dissected drawing of the flower, which is all that Jacquin has exhibited of the plant. The young tree, about seven feet high, and four inches in the diameter of its trunk, bore in the above several branches, with alternate pinnate leaves, each of four pair of oblong leaflets with an odd one, all coriaceous, obtuse with a point, undulated, sparingly and sharply serrated; smooth above; roughish to the touch beneath; the largest near six inches long; the odd one on a considerable partial stalk. The flowers are said to grow on the trunk and older branches, but of their mode of insertion or inflorescence we have no account. The calyx is ovate, tubular, smooth, paleish-green, about an inch long, with five acute, rather deep, red segments. Tube of the corolla cylindrical, pale, the length of the calyx; limb very large, bell-shaped, three inches long, with five acute, unequal, reflexed, marginal lobes; its outside strongly and copiously ribbed, pale, with a tinge of red; the whole inside of a fine crimson. The fifth stamen is apparently perfect, with an anther, though but half the length of the others; all the filaments hairy. Germen accompanied at the base by five glands. Stigma of two lanceolate plates. Berry as large as a man's head, coated, full of pulp, in which the seeds are lodged.—Jacquin was doubtful of the genus of this magnificent

scent and curious plant, which is said to form, in its native country, a very large tree. There seems as much reason to refer it to *Crescentia* as to *Tanacetum*, the calyx not answering well to either, and the internal structure of the fruit being unknown.

TANAEIM, or **TENAIEM**, in *Geography*, a town of Arabia, in the province of Yemen, famous among the Arabian Jews, who had anciently their chief seat, and many considerable synagogues in it; at present it is almost desolate; 30 miles S.E. of Sana.

TANAGA, one of the Fox islands, in the North Pacific ocean, about 40 miles in circumference. N. lat. $53^{\circ} 20'$. E. long. $182^{\circ} 14'$.

TANAGER, *Il fiume Negro*, in *Ancient Geography*, a river of Italy, in Lucania, according to Virgil. It has its source in a mountain called Albusinus, now monte Postiglione, and discharges itself into the Silanus.

TANAGRA, a considerable town of Bœotia, towards the west, seated on an eminence, at some distance from the mouth of the Asopus. In a temple of Bacchus at this town was a fine statue of this god, and above, a triton of admirable workmanship. Besides the temple of Bacchus, here were temples of Themis, Venus, Apollo, and Mercury. In the most conspicuous place of this city was the tomb of Corinna, so famous for her beauty and poetical talents, so that at Thebes she gained a prize in preference of Pindar. Here was also the tomb of Orion. Pausanias.

TANAGRA, *Tanager*, in *Ornithology*, a genus of the order Passeres; the characters of which are, that the bill is conic, acuminate, emarginated, subtrigonus at the base, and inclining at the apex. Gmelin enumerates forty-six

Species.

JACAPA. Black; the forehead, neck, and breast, crimson-coloured. This is the jacapu of Marcgrave, the red-breasted blackbird of Edwards, and the red-breasted tanager of Latham. It is found in America.

BRASILIA. Crimson, with black tail and wings. This is the cardinal of Buffon, and the Brazilian tanager of Latham. Found in South America. Of this bird there are two varieties, one of which is the rumpless blue, red, and black Indian sparrow of Willughby.

RUBRA. Red, with black wings and tail, and tail-feathers white at the apex. This is the Canada tanager of Pennant, and the red tanager of Latham. Found in Canada. Of this the scarlet sparrow of Edwards, or merula brasiliensis of Ray and Willughby, is a variety.

JACARINA. Violet-black, with wings whitish beneath, and tail of two divaricated branches. This is a bird of Brasil and Guiana, the jacarini of Marcgrave.

VIOLACEA. Violet, and the under part very yellow: the teitei of Marcgrave, the golden titmouse of Edwards, and golden tanager of Latham. A variety of this, found in Brasil, Surinam, and Cayenne, is shining black, with the abdomen, breast, and front pale yellow, and the outer tail-feather having on its inner side a white spot.

OLIVACEA. Olive; the throat and breast yellow, the abdomen white, the quills and tail-feathers brown, with a white margin. This is the olivet of Buffon, and found in Cayenne.

GYROLA. Green, red-headed, yellow collar, and ceruleous breast: the rouvardin of Buffon, the red-headed greenfinch of Edwards, and red-headed tanager of Latham. Found in various parts of South America.

CAYANA. Yellow, green back, red cap, and black cheeks. A bird of Cayenne, of which there is a variety,

VOL. XXXV.

underneath golden-coloured, back green and yellow, head ceruleous, wings and tail green.

ATRATA. Shining black: the black tanager of Latham. Found in India.

MEXICANA. Black, underneath yellowish, breast and rump blueish: the black and blue titmouse of Edwards, and black and blue tanager of Latham. The tangara barbadensis cerulea of Brisson is a variety. Found in Cayenne, Guiana, and New Spain.

TATAO. Violet, black back, yellow rump, green head, and violet breast and wings: the titmouse of paradise of Edwards, the paradise tanager of Latham, and the tangara of Brisson, Ray, Willughby, and Buffon. Found in Guiana.

ALBROSTRIS. Black, with a spot on the wings, and tail yellow, and a white beak: the white-billed tanager of Latham. Of this there is a variety. It is an American bird.

GULARIS. Black, beneath white, red head, and purple throat: the rouge-cap of Buffon, and red-headed tanager of Latham. Found in Cayenne and Guiana.

CAYENNENSIS. Black, both sides of the breast and under part of the wings yellow. Found in Brasil, Guiana, and New Spain.

BRASILIENSIS. Black, under part white, throat and rump blueish, face and breast black: the guira-genoia of Marcgrave, the turquin of Buffon, and turquoise tanager of Latham. A Brasil species.

DOMINICA. Black-spotted, above brown, and below whitish: called from the place of its residence, by Latham, the St. Domingo tanager.

MILITARIS. Brown; breast, neck, throat, and shoulders sanguineous: the military tanager of Latham, and greater bulfinch of Edwards. Found in South America.

GRISEA. Grey-olive, under grey, with wings and tail black, grey at their margin. Found in Guiana and Louisiana.

EPISCOPUS. Cinereous, with wings and tail externally blueish: the bishop tanager of Latham. Found in Cayenne.

SAYACA. Hoary, with blueish wings: the fayacu of Marcgrave. Found rarely in Cayenne.

PUNCTATA. Green, pointed with black; under yellowish-whitish: the fyacoa of Buffon, spotted green titmouse of Edwards, and spotted tanager of Latham. Found in Cayenne.

VIRENS. Green, under yellowish, cheeks and throat black: the green tanager of Latham. Found in New Spain, Peru, and Brasil.

MISSISSIPENSIS. Wholly red: the Mississippi tanager of Latham. Of this species there are two varieties; one found on the river Mississippi, and the other in New Spain.

CRISTATA. Blackish, golden crest, throat and rump yellow: the houpette of Buffon, and crested tanager of Latham. Found in Guiana.

ÆSTIVA. Red, bill yellowish: the summer red-bird of Catesby and Edwards, and summer tanager of Pennant and Latham. Found in Carolina and Virginia.

MAGNA. Olive-brown; under reddish; legs, front, and temples blueish; vent-feathers and throat red, and the middle of the throat white: the grand tanager of Latham. Found in Guiana and Cayenne.

CÆRULEA. Blueish, black bill, and light-red legs: the blue tanager of Latham. A Cayenne bird.

VARIABILIS. Green, partly blueish and partly brown, black band about the eye, quills and tail-feathers black, with green margins: variable tanager of Latham.

K

TRICOLOR.

TRICOLOR. Green; head, chin, throat, and breast pale sea-colour; black neck-band, head and sides of the neck golden-green, a large spot on the throat, and back black, the breast-band blueish, the abdomen and vent-feathers yellowish-green: the green-headed tanager of Latham. Of this there is a variety.

GUIANENSIS. Green, head cinereous-grey, front and head-band on both sides from the front to the nape red: the grey-headed tanager of Latham. Found rarely in the forests of Guiana.

NIGRICOLLIS. Olive, beneath yellow, black throat, golden breast, feathers of the wings and tail-feathers brown, with olivaceous margins: the black-throated tanager. Found in Guiana.

RUFICOLLIS. Black and blue, with a large red streak on the throat, and black wings and tail: the rufous-throated tanager of Latham. Found in Jamaica.

LEUCOCEPHALA. Black and brown, white front, reddish throat, purple breast and wings, and yellowish abdomen and vent-feathers: the quatoztli of Seba. Found in the mountains of Brazil.

FLAVA. Yellow throat, breast and spots of the abdomen black, quills and tail-feathers black, sea-coloured at the margin. This is the guiraperea of Ray and Willughby, and the yellow tanager of Latham. Found in Brazil, of the size of a lark.

AMBOINENSIS. Varied with black and blue, black vertex, blueish-green rump; cheeks, chin, throat, and breast blueish; abdomen and vent-feathers white. Found in Amboina, and called calatti.

CANORA. Blueish, varied with yellow; black tail, white at the apex; and wings partly blueish and partly yellow: the xiuhtototl of Fernandes. Found in New Spain.

SINENSIS. Olivaceous, beneath yellow, with the quills and tail-feathers black, yellow at their margin: the Chinese tanager of Latham.

BONARIENSIS. Black and violet, with a slight greenish tint in the wings and tail: the violet tanager of Latham.

ATRA. Cinereous, with the face, chin, and throat black, (those of the female yellow:) the camail or cravatte of Buffon, and black-faced tanager of Latham. Found in Guiana.

PILEATA. Blueish-cinereous, beneath silvery, with the vertex, temples, and sides of the neck black, and the ocular spot white; the hooded tanager of Latham. Of this the tje-piranga of Ray and Willughby is a variety. Found in Guiana and Brazil.

MELANICTERA. Above ferruginous, beneath very yellow, head and nape black, wings streaked with white, and tail brown: the black-crowned tanager of Latham. Found on the Caucasus and in Georgia.

SIBIRICA. Black, the tips of the down between the shoulders and the rump ciliated with white. A Siberian tanager.

ATRICAPILLA. Reddish and rufous; head, tail, and wings shining black, with a roundish tail: the mordoré of Buffon, and black-headed tanager of Latham. Found in Guiana.

SERIATA. Beneath yellow, with a head striated with black and blue, back above blackish and beneath golden, quills and tail-feathers black, with a blue margin: the onget of Buffon, and furrow-clawed tanager of Latham. Found in South America.

NIGERRIMA. Black, with a white spot within the wings: the Guiana tanager of Latham.

CAPENSIS. Above ferruginous-brown, beneath ferru-

ginous, varied with white; the middle of the tail black, its sides ferruginous-rufescent, the bill yellowish, the legs black. Found at the Cape of Good Hope.

TANAH, in *Geography.* See **SAN.**

TANAIS, the *Don,* in *Ancient Geography,* a large river which had its rise towards the east, in the territory of the Thyrsagetes, traversed the country of the Sarmatians, turned its course to the south, and discharged itself in the lake of Mæotis. Its course was so rapid, that it never froze. Its borders were inhabited by the Sarmatians. The two mouths of the Tanais were distant 70 stadia from one another, according to Strabo.—Also, a town of European Sarmatia, situated between the mouths of the river of the same name.—Also, a river of Africa, which ran into the Mediterranean, towards the south-west, at five miles from Thena.

TANAIS, in *Mythology,* a divinity peculiar to the Armenians, to whom were consecrated the slaves of both sexes; and it is also said, that the people of better rank offered to him their daughters, who, as soon as they were consecrated to this god, were authorized by the law to prostitute themselves to the first comer, until the time of their marriage. Nor did this conduct by any means prevent the addresses of suitors.

TANAK POINT, in *Geography,* a cape on the north coast of Java. S. lat. 6° 24'. E. long. 108° 36'.

TANAKAKA, a small island near the south-west coast of Celebes, belonging to the Dutch. S. lat. 5° 30'. E. long. 119° 42'.

TANALITZKAIA, a fortress of Russia, in the government of Upha, at the conflux of the Urdafim and Ural; 120 miles E. of Orenburg.

TANAMBE, a town on the east coast of Madagascar. S. lat. 16° 20'. E. long. 50° 20'.

TANAON, a town on the east coast of the island of Leyta. N. lat. 11° 10'. E. long. 125° 1'.

TANAOSIMA, one of the Japanese islands, about 100 miles in circumference. N. lat. 30° 20'. E. long. 132° 30'.

TANARGUE, a mountain of France, which gives name to a district in the department of the Ardèche; 20 miles S.W. of Privas.

TANARO, one of the six departments of Piedmont, after its union with the French republic, August 26, 1802, formerly Acqui and Asti, in N. lat. 44° 45', west of Marengo, containing 197 square leagues, and 311,458 inhabitants. It was divided into three circles, viz. Asti, including 131,910; Acqui, 82,914; and Alba, 96,634 inhabitants. The soil is broken by torrents, which form many lakes and marshes. The south-west district consists of barren spots and fruitful vallies; the northern part is fertile, and the hills yield abundance of wine of an inferior quality. The principal products of the department are grain, fruits, and pastures, with quarries of stone, mineral springs, &c.

TANARO, a river of France, which rises in the mountains near Tenda, passes by Coni, Cherasco, Alba, Asti, Alexandria, &c. and joins the Po, 3 miles E. of Valenza.

TANARUS, the *Tanaro,* in *Ancient Geography,* a river of Italy, in Liguria, which having been formed by the confluence of many rivers, discharged itself into the Padus, north-west of Dertona.

TANASSERIM, in *Geography.* See **SIAM.**

TANAVELLE, a town of France, in the department of the Cantal; 4 miles W.S.W. of St. Flour.

TANAW, a town of Napaul: 45 miles S.W. of

TANBAY, a town on the E. coast of the island of Negros. N. lat. $10^{\circ} 3'$. E. long. $123^{\circ} 1'$.

TANCACA, a town of Mexico, in the province of Guafteca; 50 miles W.S.W. of St. Yago de los Valles.

TANCALE, a town of Mexico, in the province of Guafteca; 50 miles N.W. of St. Yago de los Valles.

TANCANCHY, a town of Hindoostan, in Madura; 8 miles S. of Vadagary.

TANCARVILLE, a town of France, in the department of the Lower Seine; 10 miles S.E. of Montevilliers.

TANCHOY, a town of Mexico, in the province of Guafteca; 35 miles N. of Panuco.

TANCICUY, a town of Mexico, in the province of Guafteca; 15 miles S.W. of Panuco.

TANCOA, a town of Abyssinia; 40 miles N.N.E. of Miné.

TANCOBANCA, a river of Persia, which runs into the sea, 69 miles W.N.W. of Port Jaques.

TANCOS, a town of Portugal, in Estremadura, at the conflux of the Zezare and the Tagus; 21 miles N.E. of Santarem.

TANCUYLABO, a town of Mexico, in the province of Guafteca; 30 miles S.S.E. of St. Yago de los Valles.

TANCYTOWN, a post-town of Maryland; 27 miles N.E. of Fredericktown.

TANDA, a town on the east coast of the island of Mindanao. N. lat. $8^{\circ} 48'$. E. long. $126^{\circ} 12'$.

TANDA, or *Tanrah*, a town of Hindoostan, called sometimes *Chawaspour Tanda*, from the original name of the district in which it was situated. It was a short time, in the reign of Shere Shaw, about the year 1540, the capital of Bengal, and became the established capital under Acbar, about 1580. It is situated very near to the scite of Gour, on the road leading from it to Rajemal. There is little remaining of this place, save the rampart; nor do we know for certain when it was deserted. In 1659 it was the capital of Bengal, when that subah was reduced under Aurungz-be.

TANDAH, a town of Bengal; 12 miles S.E. of Calcutta.

TANDAM, a town of Bootan; 57 miles N. of Dinagepour.

TANDAMORGONG, a town of Hindoostan, in Goonđwanah; 25 miles E. of Nagpour.

TANDEGO, a town of Africa, on the St. Domingo river; 25 miles E. of Farim.

TANDERAGEE, a post-town of the county of Armagh, Ireland, which has a good linen market. It is near the Newry canal, and 61 miles N. by W. from Dublin.

TANDLA, a town of Hindoostan, in Malwa; 72 miles W. of Ougein. N. lat. $23^{\circ} 5'$. E. long. $74^{\circ} 30'$.

TANDOO BAAS, a small island in the Sooloo Archipelago. N. lat. $5^{\circ} 8'$. E. long. $120^{\circ} 15'$.

TANDOO Battoo, a small island in the Sooloo Archipelago. N. lat. $5^{\circ} 9'$. E. long. $120^{\circ} 12'$.

TANDORF, a town of Bohemia, in the circle of Koniggratz; 20 miles E. of Koniggratz.

TANE, a river of Finmark, which runs into the Frozen sea, N. lat. $70^{\circ} 48'$.

TANE. See TAROATAIHETOOMO.

TANG, in *Geography*, a town of Sweden, in West Gothland; 30 miles E.N.E. of Uddevalla.

TANGA, in *Commerce*, a money of account at Goa, in the East Indies; some of which are good, and others bad. A pardo is worth 4 good tangas or 5 bad; 16 good vintins, or 20 bad, are equal to 300 good bafaruccos, or 360 bad. The coins are the St. Thomas, a gold piece of money of

nearly the weight of a ducat, which passes for 11 good tangas, more or less. The silver coins are the pardo xeraphin of 5 good tangas, and the common pardo of 4 good tangas. The copper and tin coins are the good and bad bafaruccos. Venetian sequins are worth 16 good tangas; pagodas, 10 good tangas; and Spanish dollars, 550 good bafaruccos, all more or less. A good tanga is worth about $7\frac{1}{2}d$ sterling; a pardo, 2s. 6d.; and a xeraphin, 3s. $3\frac{1}{2}d$. sterling nearly. Kelly's Cambiil.

TANGALA, in *Geography*, a small island in the East Indian sea, near the S. coast of Java. S. lat. $8^{\circ} 20'$. E. long. $111^{\circ} 45'$.

TANGALE, a town of the island of Ceylon; 92 miles S. of Candy.

TANGARAC, in *Botany*, a poisonous Brazilian plant; but the root, says Piso, is an antidote to the leaves, flowers, and fruit. Boyle's Works, Abr. vol. i. p. 14.

TANGAWA, in *Geography*, a town of Japan, in the island of Ximo; 30 miles S.E. of Kokura.

TANGE, a town of Sweden, in West Gothland; 21 miles N. of Gotheburg.

TANGEN, a town of Norway, in the province of Aggerhuus; 2 miles E. of Stromsoe.

TANGENE, a town of Sweden, in West Gothland; 26 miles E. of Uddevalla.

TANGENT, in *Geometry*, a right line which touches a circle, that is, meets it in such manner, as that, though infinitely produced, it would never cut the same; that is, never come within the circumference.

Thus the line AD (*Plate XV. Geometry, fig. 3.*) is a tangent to the circle in D.

It is demonstrated in geometry; 1. That if a tangent, AD, and a secant, AB, be both drawn from the same point, A; the square of the tangent will be equal to the rectangle, under the whole secant AB, and that portion of it, AC, which falls without the circle.

2. That if two tangents, AD, AE, be drawn to the same circle from the same point A, they will be equal to each other.

As a right line is the tangent of a circle, when it touches the circle so closely, that no right line can be drawn through the point of contact between it and the arc, or within the angle of contact that is formed by them; so in general, when any right line touches any arc of a curve, in such a manner that no right line can be drawn through the point of contact, betwixt the right line and the arc, or within the angle of contact that is formed by them, then is that line the tangent of the curve at the said point.

The tangent of an arc is the right line that admits the position of all the secants that can pass through the point of contact, though, strictly speaking, it is no secant. Macl. Flux. art. 181. 505.

TANGENT, in *Trigonometry*.—A tangent of an arc is a right line, raised perpendicularly on the extreme of the diameter, and continued to a point, where it is cut by a secant, that is, by a line drawn from the centre through the extremity of the arc of which it is a tangent.

A tangent of an arc A (*Plate II. Trigonom. fig. 13.*) is a part of a tangent of a circle (that is, of a right line, which touches a circle without cutting it), intercepted between two right lines drawn from the centre C, through the extremes of the arc E and A.

Hence the tangent FE is perpendicular to the radius EC.

And hence the tangent FE is the tangent of the angle ACE, as also of that of ACI; so that two adjacent angles have only the same common tangent.

TANGENT.

TANGENT, Co, or Tangent of the Complement, is the tangent of an arc, which is the complement of another arc to a quadrant.

Thus a tangent of the arc AH , is the co-tangent of the arc AE , or the tangent of the complement of the arc AE .

To find the length of the tangent of any arc, the sine of the arc being given: suppose the arc AE , the given sine AD , and the tangent required EF . Since both the sine and tangent are perpendicular to the radius EC , they are parallel to each other. Wherefore as the cosine DC is to the sine AD , so is the whole sine to the tangent EF . See **SINE**.

Hence, a canon of sines being had, a canon of tangents is easily constructed from it.

TANGENTS, Artificial, are the logarithms of the tangents of arcs.

TANGENTS, Line of, is a line usually placed on the sector, and Gunter's scale; the description and uses of which, see under **SECTOR**.

TANGENT of a Conic Section, as of a parabola, is a right line, which only touches or meets the curve in one point, and does not cut or enter within the curve. See **CONIC SECTIONS**.

TANGENTS, Method of, is a method of drawing tangents to any algebraical curve, or of determining the magnitude of the tangent and sub-tangent, the equation to the curve being given.

The method of tangents is nearly related to that of *maxima et minima*; and the same authors, who in the early state of algebra attempted one of those cases, never failed of touching also on the other. Hence we have the methods of Descartes, Fermat, Roberval, Hudde, &c. We have already explained under the article *MAXIMA et MINIMA*, the several methods of these authors relating to the latter subject; and as their methods of tangents differ in no respect from this, we shall not repeat them again in this place, but merely explain the principle which led to so intimate a connection between the two problems.

Descartes' Method of Tangents.—It has been shewn under the article above referred to, that Descartes' method of maxima and minima, depended upon his making two roots of his equation equal to each other, and the same principle led him also to his problem of tangents.

Let us conceive, for example, a curve ABb , (*Plate XIV. Analysis, fig. 16.*) described on an axis AC ; and from any point in this axis, C , as a centre, let there be described a circle, which shall cut the curve at least in two points, as B, b ; from these draw two ordinates, which will necessarily be common both to the circle and curve: let us now imagine the radius of this circle to decrease, while its centre remains fixed; and it is obvious that thus the two points of intersection will approach each other, and finally coincide, in which case the circle will touch the curve at the point E , and the tangent at that point will be common to both, and perpendicular to the radius of the circle at that point. Thus the problem of determining the tangent to a curve, is reduced to finding the position of a perpendicular to the curve, drawn from any point in its axis. In order to effect this, Descartes sought, in a general manner, the points of intersection in the curve made by a circle described with a given radius from a given point in the axis. He thus arrived at an equation, which, in the case of two intersections, ought to contain two unequal roots, expressing the distance of the two ordinates from the vertex of the curve. But when the two points of intersection are united in one, as in the case of the circle touching the curve, then the two roots of the equation are necessarily equal to each other. His object, therefore, was, in the equation first obtained, and of

which the co-efficients were indeterminate, to give them such values, that the two roots should be equal; for which purpose, he compared the proposed equation with an equation of the same degree, having two equal roots; and hence, by equating the co-efficients, obtained the value of those in his first equation.

In order to illustrate this, let ABb (*fig. 16.*) be a parabola, and Bb a circle. Make $CA = a$, $AD = x$, the radius $CB = r$, then $CD = a - x$; and since the ordinate BD belongs to the circle, we have

$$y^2 = r^2 - CD^2 = r^2 - (a - x)^2 = r^2 - a^2 + 2ax - x^2.$$

But the same ordinate belonging also to the parabola, we have from the known property of that curve, $y^2 = px$, p being the parameter; therefore

$$\begin{aligned} r^2 - a^2 + 2ax - x^2 &= px, \text{ or} \\ x^2 + (p - 2a)x + (a^2 - r^2) &= 0, \end{aligned}$$

which, being an equation of the second degree, must necessarily have two roots, or values, of x , answering to the two abscissas AD, Ad : for we should arrive at the same conclusion, if our equation had been deduced with reference to the point b ; and it is obvious that these roots depend entirely upon the relation of the co-efficients $(p - 2a)$ and $(a^2 - r^2)$, or upon the ratio of the quantities a, p , and r , to each other; and, consequently, such values may be given to these quantities, that the two values of x may be equal.

In order to find this ratio, Descartes formed an equation of the second degree, having two equal roots, as $x^2 - 2ex + e^2 = 0$, *viz.* $(x - e)(x - e) = 0$; and comparing this with that found above, he obtained the equation $x - a = CD = \frac{1}{2}p$, which shews that in the parabola, the sub-normal is equal to half the parameter; whence it also follows, that the sub-tangent is equal to double the abscissa, which is the known property of the curve.

Descartes had also another method for tangents, a little different from the above in practice, although it was the same in principle; thus he conceived a right line to revolve about a fixed point in the axis of the curve produced, which at first should cut the curve in a certain number of points, but by its revolution, these points of intersection approaching each other would finally coincide, and thus the revolving line become a tangent to the curve. For this purpose he also first obtained the general equation, which he afterwards equated with another having two equal roots, and thus determined the several relations of his indeterminate co-efficients, exactly as in the case above given.

Fermat's Method of Tangents.—It will be found by comparing the above method of tangents of Descartes, with that of his maxima and minima, that the two ultimately depend upon the same principle, *viz.* of making two roots of an equation equal to each other; and the coincidence of Fermat's methods for these two problems is still more obvious; in fact, he scarcely treats of them as distinct cases, but refers immediately for the solution of the case of tangents to that of his maxima and minima. In order, says this author, that a line may be a tangent to a curve, as for example to the parabola ABb , at the point b , (*fig. 17.*) it is evident that every ordinate, except BC , will meet that tangent beyond the curve, as in C . Thus the ratio of $BC^2 : ce^2$, which is the same as $CD^2 : cD^2$, will be less than that of $CB^2 : cb^2$, or than that of CA to cA ; but if we suppose these ratios to be the same, and consequently the distance cC to vanish, the points B, b , will coincide, and we shall have an equation, which, treated in the same manner as in his method *de maximis et minimis*, will give the ratio of $CD : CA$.

TANGENT.

As to the methods proposed by Hudde, Roberval, Huygens, &c. they differ from those given above, only in the same manner as in their methods of maxima and minima; it would therefore be useless to describe them in this place.

Barrow's Method of Tangents.—It is obvious from what is said above, and what has been stated under the article *MAXIMA et MINIMA*, that both the method of tangents, and that for the greatest and least ordinates, were very nearly related to the present fluxional way of treating the same subjects; but with regard to tangents, a still nearer approach was made by Dr. Barrow.

This accurate geometer considered the little triangle formed by the difference of the two ordinates, their distance from each other, and the indefinitely small part of the curve, as similar to that which is formed by the ordinate, the tangent, and sub-tangent. He then sought by the equation of the curve, the ratio of the two sides ba , Ba , (*fig. 18.*) of the triangle Bba , when the difference of the ordinates is infinitely little; and then said, as $ba : Ba ::$ ordinate Bp : the sub-tangent Tp .

In the case of the parabola, for example, whose equation is $y^2 = px$; supposing Pp the increase of the absciss = e , and ba the corresponding increase of the ordinate $y = a$; then the equation for the ordinate $p b$ becomes

$$(y + a)^2 = p(x + e), \text{ or}$$

$$y^2 + 2ay + a^2 = px + pe.$$

Subtracting from both sides $y^2 = px$, there remains

$$2ay + a^2 = pe.$$

Also a being itself infinitely small, its square a^2 may be entirely neglected, and there results $2ay = pe$; therefore $a : e :: p : 2y$; but $a = ba$, and $e = Ba$, also $y = \sqrt{px}$; therefore, from the proposition stated above, *viz.*

$$ab : aB :: \text{ordinate} : \text{subtangent},$$

we have

$$p : 2\sqrt{px} :: \sqrt{px} : 2x, \text{ the subtangent required.}$$

Such were the principles employed in the solution of this interesting problem prior to the brilliant discovery of the fluxional calculus, which from its generality supplanted them all, and they are now therefore merely matters of historical curiosity; but as they exhibit the flow and progressive advances of genius and science towards an ultimate state of perfection, they are highly deserving of the attention of the mathematician, who will find in them much to admire; they will at the same time enable him duly to appreciate the transcendent talents of that great philosopher, who formed out of them one general and comprehensive principle of solution, which will apply with equal facility to algebraical curves of every order.

The Method of Tangents according to the Doctrine of Fluxions.—Its use is very great in *Geometry*; because in determining the tangents of curves, we determine at the same time the quadrature of the curvilinear spaces: on which account it well deserves to be here particularly insisted on.

To find the Sub-tangent in any algebraic Curve.—Let the proposed curve be $A M O$ (*Plate XIV. Anal. fig. 19.*), and the right line $T M Q$ a tangent to it at the point M ; let the semiordinate $p m$ be infinitely near another $P M$, and $M R$ parallel to $A H$; then the relative celerities of the point M , moving along the curve from A towards O , in the directions $M R$ and $P M$, with which $A P$ and $P M$ increase in this position, will be truly expressed by $M R$ and $R m$; but the celerities by which quantities increase are as the fluxions of those quantities; therefore ($M m$ being the fluxion of the curve line $A M$) $M R$ and $R m$ are the corresponding

fluxions of the absciss $A P$, and the ordinate $P M$; and, because the triangles $M m R$ and $T M P$ are similar, we have $R m : M R :: P M : P T$. Let, therefore, the absciss $A P$ be put = x , and the ordinate $P M = y$, and we shall have

$$y : \dot{x} :: y : \frac{y \dot{x}}{y} = P T. \text{ By means of this general expres-}$$

sion for the sub-tangent, and the equation of the curve expressing the relation between x and y , the ratio of the fluxions \dot{x} and \dot{y} will be found, and from thence the length of the sub-tangent; whence the tangent itself may be easily determined and drawn. This we shall illustrate in the following examples:

I. The equation defining a circle is $ax - x^2 = y^2$; and by taking the fluxions of these quantities, $a\dot{x} - 2x\dot{x} =$

$$2y\dot{y}; \text{ consequently } \frac{\dot{x}}{\dot{y}} = \frac{2y}{a - 2x} = \frac{y}{\frac{1}{2}a - x}; \text{ and, multi-}$$

plying both sides by y , we have $\frac{y\dot{x}}{\dot{y}} = \frac{y^2}{\frac{1}{2}a - x} =$ the sub-

tangent $P T$ (*see fig. 20.*); whence $(\frac{1}{2}a - x)$, or $A C - A F$, *i.e.* $C P : (y) P M :: (y) P M : P T$; a property of the circle deduced from the principles of common geometry.

II. The equation defining the common parabola is $ax = y^2$, a being the parameter, x the absciss, and y the or-

dinate; hence $a\dot{x} = 2y\dot{y}$, and $\frac{\dot{x}}{\dot{y}} = \frac{2y}{a}$; consequently,

$$\frac{y\dot{x}}{\dot{y}} = \frac{2y^2}{a} = \frac{2ax}{a} = 2x; \text{ therefore the sub-tangent } P T$$

(*fig. 19.*) is the double of its corresponding absciss $A P$; which is a well-known property of the parabola.

III. The general equation for the parabolas of any kind being $a^m x^n = y^{m+n}$; we have $n a^m x^{n-1} \dot{x} = \overline{m+n} x$

$$y^{m+n-1} \dot{y}; \text{ and, therefore, } \frac{\dot{x}}{\dot{y}} = \frac{\overline{m+n} x y^{m+n-1}}{n a^m x^{n-1}}; \text{ whence}$$

$$\frac{y\dot{x}}{\dot{y}} = \frac{\overline{m+n} x y^{m+n}}{n a^m x^{n-1}} = \frac{\overline{m+n} x a^m x^n}{n a^m x^{n-1}} \text{ (because } y^{m+n} = a^m x^n \text{)}$$

$$= \frac{\overline{m+n}}{n} x = \text{the true value of the sub-tangent; which,}$$

therefore, is to the absciss in the constant ratio of $\overline{m+n}$ to n .

IV. The equation defining an ellipsis is $b^2 \times ax - x^2 = a^2 y^2$, $A P$ (*fig. 21.*) being = x , $M P = y$, $A B = a$, and the lesser axis = b ; for by the property of the ellipsis, we have $a^2 : b^2 :: ax - x^2 (A P \times P B) : y^2 (M P^2)$; and, therefore, $b^2 \times ax - x^2 = a^2 y^2$; whence $b^2 \times$

$$\overline{ax - 2x\dot{x}} = 2a^2 y\dot{y}, \text{ and } \frac{\dot{x}}{\dot{y}} = \frac{2a^2 y}{b^2 \times a - 2x}; \text{ and, con-}$$

$$\text{sequently, the sub-tangent } P T \left(\frac{y\dot{x}}{\dot{y}} \right) = \frac{2a^2 y^2}{b^2 \times a - 2x} =$$

$$\frac{a^2 y^2}{b^2 \times \frac{1}{2}a - x} = \frac{b^2 \times ax - x^2}{b^2 \times \frac{1}{2}a - x} = \frac{ax - x^2}{\frac{1}{2}a - x}; \text{ whence the point}$$

T being given, through which the tangent must pass, the tangent itself may be drawn.

V. Because the equation, exhibiting the nature of all kinds

TANGENT.

To determine the tangents of curves, supposed to be described by the interfections of right lines revolving about given poles, see Mr. Maclaurin's Fluxions, art. 210, seq. In finding the tangents of curves by the method of infinitesimal differences, it has been objected that the conclusion is found by a double error. 1. By taking the curve for a polygon of an infinite number of sides. 2. By the false rule for taking the differential of a power. But there is no need of such suppositions in the method of fluxions, for it may be geometrically demonstrated, that the fluxions of the base, ordinate, and curve, are in the same proportion to each other, as the sides of a triangle respectively parallel to the base, ordinate, and tangent. When the base is supposed to flow uniformly, if the curve be convex towards the base, the ordinate and curve increase with accelerated motions; but their fluxions at any term are the same as if the point which describes the curve had proceeded uniformly from that term in the tangent. Any farther increment which the ordinate or curve acquires, is to be imputed to the acceleration of the motions with which they flow. See Maclaurin's Fluxions, book i. chap. vii. and viii.

Any two arcs of curve lines touch together, when the same right line is the tangent of both at the same point. But when they are applied to each other in this manner, they never perfectly coincide, unless they be similar arcs of similar and equal figures.

In the Philosophical Transactions, we have the following method of drawing tangents to all geometrical curves, without any labour or calculation, by M. Slufius.

Suppose a curve, as DQ (*Plate XV. Anal. fig. 3.*) whose points are all referrible to any right line given, as EA B, whether that right line be the diameter or not; or whether there be more given right lines than one, provided their powers do but come into the equation. In all his equations, he puts v for the line DA, y for BA; and for EB, and the other given lines, he puts b , d , &c. that is, always consonants only.

Then, supposing DC to be drawn touching the curve in D, and meeting with EB produced in C, he calls the sought line, CA, by the name of a .

To find which, he gives this general method. 1. Reject out of the equation all members which have not either v or y in them; then put all those that have y on one side, and all those which have v on the other; with their signs + or -; and the latter, for distinction and ease sake, he calls the right, the former the left side. 2. On the right side, let there be prefixed to each member the exponent of the power, which v hath there; or, which is the same thing, let that exponent be multiplied into all the members. 3. Let the same be done also on the left side, multiplying each member there by the power of the exponent of y ; adding this moreover, that one y must, in each part, be changed into a . This done, the equation thus reformed will shew the method of drawing the required tangent to the point D; for, that being given, as also y , v , and the other quantities expressed by consonants, a cannot be unknown. Suppose an equation $by - yy = vv$, in which EB is called b ; BA = y , DA = v , and let a , or AC, be required so as to find the point C, from whence CD being drawn, shall be a true tangent to that curve QD in D. In this example, nothing is to be rejected out of the equation, because y or v are in each member: it is also disposed, as required by the rule 1; to each part, therefore, there must be prefixed the exponent of the powers of y or v , as in the rule 2; and on the left side, let one y be changed into a , and then the equation will be in this form, $ba - 2ya = 2vv$, which equa-

tion reduced, gives easily the value of $a = \frac{2vv}{b - 2y} = AC$.

And so the point C is found, from which the tangent DC may be drawn.

To determine which way the tangent is to be drawn, whether towards B or E, he directs to consider the numerator and denominator of the fraction. For, 1. If in both parts of the fraction all the signs are affirmative; or if the affirmative ones are more in number; then the tangent is to run towards B. 2. If the affirmative quantities are greater than the negative in the numerator, but equal to those in the denominator, the right line drawn through D, and touching the curve in that point, will be parallel to AB; for in this case a is of an infinite length. 3. If in both parts of the fraction the affirmative quantities are less than the negative, changing all the signs, the tangent must be drawn now also towards B; for this case, after the change, comes to be the same as the first. 4. If the affirmative quantities are greater than the negative in the denominator, but in the numerator are less, or *vice versa*, then changing the signs in that part of the fraction where they are less, the tangent must be drawn a contrary way; that is, AC must be taken towards E. 5. But whenever the affirmative and negative quantities are equal in the numerator, let them be how they will in the denominator, a will vanish into nothing; and, consequently, the tangent is either AD itself, or EA, or parallel to it; as will easily be found by the data. This he gives plain examples of, in reference to the circle, thus: let there be a semicircle, whose diameter is EB; in which there is given any point, as D (*fig. 4.*), from which the perpendicular DA is let fall to the diameter. Let DA = v , BA = y , BE = b : then the equation will be $by - yy = vv$, and drawing the tangent DC, we have AC, or $a =$

$\frac{2vv}{b - 2y}$. Now, if b be greater than $2y$, the tangent must

be drawn towards B; if less, towards E; if it be equal to it, it will be parallel to EB, as was said in the first, second, and fourth rules.

Let there be another semicircle inverted, as NDD (*fig. 5.*), the points of whose periphery are referred to the right line BE, parallel and equal to the diameter. Let NB be called d , and all things else as before; then the equation will be $by - yy = dd + vv - 2dv$; which being managed according to his rules, you have $a = \frac{2vv - 2dv}{b - 2y}$.

Now, since v here is supposed to be always less than d ; if b be greater than $2y$, then the tangent must be drawn towards E; if equal, it will be parallel to BE; if less, changing all the signs, the tangent must be drawn towards B, as by rules fourth, fifth, and third. But there could be no tangent drawn, or at least EB would be it, if NB had been taken equal to the diameter. Let there be another semicircle, whose diameter NB (*fig. 6.*) is perpendicular to EB, and to which its points are supposed to be referred.

Let NB be called b , and all things else as above; the equation will be $yy = bv - vv$, and $a = \frac{bv - 2vv}{2y}$. If,

now, b be greater than $2v$, the tangent must be drawn towards B; if less, towards E; if equal, DA will be the tangent, as appears by rules fourth and fifth.

TANGENTS, *Inverse Method of*, is a method of finding the equation, or the construction, of any curve; from the tangent

gent of any other line, whose determination depends on the tangent given.

This method is also one of the great results of the new *calculus integralis*.

Its application we shall give in what follows. The fluxional expressions of the tangent, sub-tangent, &c. being delivered under the last article, if you make the given value equal to the fluxional expression, and either sum up the fluxional equation, or, if that cannot be, construct it, the curve required is had. For example :

1. To find the curve-line, whose sub-tangent = $\frac{2y^2}{a}$.

Since the sub-tangent of an algebraic line is $\frac{y\dot{x}}{\dot{y}}$; we

have $\frac{y\dot{x}}{\dot{y}} = \frac{2y^2}{a}$, and $ay\dot{x} = 2y^2\dot{y}$, and $a\dot{x} = 2y\dot{y}$;

therefore (taking the fluents by the inverse method of fluxions) $ax = y^2$.

The curve sought, therefore, is a parabola; whose construction is shewn under PARABOLA.

2. To find the curve, whose sub-tangent is a third proportional to $\frac{1}{2}a - x$ and y . Since $\frac{1}{2}a - x : y :: y : \frac{y\dot{x}}{\dot{y}}$, we

have $\frac{1}{2}a - x : y :: y\dot{y} : y\dot{x} :: \dot{y} : \dot{x}$; consequently $\frac{1}{2}a\dot{x} - x\dot{x} = y\dot{y}$, and, taking the fluents, $\frac{1}{2}ax - \frac{1}{2}x^2 = \frac{1}{2}y^2$, i. e. $ax - x^2 = y^2$. The curve sought is, therefore, a circle.

3. To find a line, wherein the sub-tangent is equal to the semiordinate. Since $\frac{y\dot{x}}{\dot{y}} = y$; $y\dot{x} = y\dot{y}$, and $\dot{x} = \dot{y}$; therefore $x = y$.

Hence it appears, that the line sought is a right line, which respects the cathetus of an equicrural triangle, as an axis, or the hypotenuse of an equicrural rectangled triangle. If x had been taken for the arc of a circle, the line sought had been a cycloid.

TANGER, in *Geography*, a river of Westphalia, which runs into the Elbe at Tangermunde.

TANGERE, *Noli me*. See NOLI.

TANGERMUNDE, in *Geography*, a town of Westphalia, in the Old Mark of Brandenburg, situated on the Elbe, where vessels pay a toll: the chief trade of the town is brewing; 24 miles N. of Magdeburg. N. lat. $52^\circ 32'$. E. long. $12^\circ 2'$.

TANGHOO, or TENHOA, a capital of a province of Tonquin, situated on a small river near the W. coast of the gulf of Cochinchina. Rice and cattle constitute the chief riches of the province. The town is called "Cuabang." N. lat. $19^\circ 40'$.

TANGIA, a town of Arabia, in the province of Hedjaz; 50 miles W.N.W. of El Catif.

TANGIBLE. See TACTILE.

TANGIER ISLANDS, in *Geography*, several islands of the Chesapeake, near the coast of Maryland, opposite to the mouth of the Potomack. N. lat. $38^\circ 12'$. W. long. $76^\circ 12'$.

TANGIERS, anciently called *Tinjis* and *Tingia*, and now by the Arabs *Tinjab*, a town of Africa, in Fez, situated at the western mouth of the straits of Gibraltar, about a day's journey from Tetuan. This town was first possessed by the Romans, who took it under Sertorius; next by the Goths; and it was surrendered by count Julian to the Saracens. It was taken in 1471 by Alonso, king of Portugal; and given

to Charles II., king of England, in 1662, as a marriage portion with the princess Catherine of Portugal. The English abandoned it in 1684, after destroying the mole and fortifications. Although now almost in ruins, it still retains some batteries, in tolerable condition, facing the bay; at the bottom of which are a river, and the remains of the bridge of Old Tangiers; but on account of the accumulated sand, the bridge, if it had continued, as well as the river, would be useless. The bay of Tangiers, independently of Ceuta, is so situated, being the narrowest part of the straits, that it must be favourable to Moorish piracy; but Tangiers can never be a commercial town, as it has few productions in its vicinity; the Spaniards, however, formerly shipped in this place, eggs, vegetables, and some fruits; and the English at present obtain supplies for their garrison at Gibraltar. The bay of Tangiers is not very safe when the wind is in the west, having been encumbered by the ruins of the mole and fortification, as the cables are liable to be rent, and the ships to be driven on shore. The best anchorage for frigates and the larger vessels, is at the eastern point, whence they may easily sail whatever way the wind sets: however, the bay is only dangerous in winter; 108 miles N.N.W. of Fez, and 38 W.S.W. of Gibraltar. N. lat. $35^\circ 42'$. W. long. $5^\circ 50'$. Chenier's Morocco.

TANGLAKE, in *Ichthyology*, the viviparous blenny of Pennant; the *mustela vivipara* of Willughby, Ray, &c.; and the *blennius viviparus* of the Linnean system.

TANGMEW, in *Geography*, a town of the Birman empire, on the right bank of the Ava; 10 miles N.W. of Promé.

TANGO, a town of Japan, in the island of Niphon; 65 miles S.W. of Meaco.

TANGOLOTANGO, a seaport town of Mexico, in the province of Guaxaca, near the gulf of Mexico; 100 miles S.S.E. of Guaxaca. N. lat. $16^\circ 8'$. W. long. $97^\circ 36'$.

TANGONE, a town of New York; 9 miles W. of Kingston.

TANGOUI, a town on the east coast of Madagascar. S. lat. $10^\circ 5'$. E. long. $49^\circ 12'$.

TANGOULLIO, a town of Asiatic Turkey, in Nalolia; 70 miles E.S.E. of Smyrna.

TANGU, a city of Pegu, and capital of a province which was formerly a kingdom; situated a considerable distance to the north of Pegu.

TANGUEY, or TONGUEY, a town of Chili, on the coast. S. lat. $30^\circ 30'$.

TANGUIA, a river of Chinese Tartary, which rises near mount Ilha, and running nearly south, falls into the river Ya-lou-kiang.

TANGULAW, a small island in the Spanish Main, near the Mosquito shore. N. lat. $13^\circ 35'$. W. long. $83^\circ 55'$.

TANGUT. See THIBET.

TANG-YANG, a lake of China, about thirty miles in circumference; 32 miles N. of Hoai-ngan.

TANIALA, a town of Hindoostan, in Palnaud; 25 miles E.N.E. of Timercotta.

TANIBOUCA, in *Botany*, a Caribæan name, to be tolerated only till the genus is properly understood.—Aubl. Guian. 448. Juss. 76.—Class and order, *Decandria Monogynia*. Nat. Ord. *Elæagni?* Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, bell-shaped, internally downy; its limb in five deep, roundish, acute segments. *Cor.* none. *Stam.* Filaments ten, thread-shaped, inserted into the tube of the calyx, as long as its limb; anthers oval, of two lobes. *Pist.* Germen inferior, roundish; style solitary, thread-shaped, curved; stigma simple. *Pist.* . . .

Eff. Ch. Calyx bell-shaped, five-cleft, superior. Corolla none. Fruit

1. *T. guianensis*. Aubl. t. 178.—Native of marshes in Guiana, flowering in May. A tree, whose trunk is twenty feet, or more, in height, and two feet in diameter, with a whitish, light and brittle wood; the bark greyish. Branches spreading every way; their young shoots leafy at the ends. Leaves deciduous, alternate, stalked, obovate, pointed, entire, coriaceous, smooth; the largest seven inches long, and three broad. Spikes axillary, solitary, stalked, about three or four inches long, of many small, alternate, greenish, fragrant flowers, clothed internally with white hairs. Aublet not having met with the fruit, nor having been able to determine any thing of the internal structure of the minute germen, we are left in great doubt as to the essential character of this genus, and even its natural order. Nothing is recorded of its use or qualities.

TANICHI, in *Geography*, a town of Hindoostan, in the Carnatic; 16 miles S.S.W. of Trichinopoly.

TANILA, a river of Mexico, which runs into the gulf of Mexico, N. lat. $18^{\circ} 10'$. W. long. $95^{\circ} 6'$.

TANINGE, a town of France, in the department of the Lemau; 24 miles S.E. of Geneva.

TANJONG Currang, a town on the west coast of the island of Lomboek. S. lat. $8^{\circ} 31'$. E. long. $115^{\circ} 48'$.

TANJONG Putus, a town of Malacca, on the north side of the river Pera, where the Dutch have a factory.

TANJORE, a country of Hindoostan, included in the Carnatic; bounded on the north and west by part of the Carnatic, and on the east and south by the gulf of Bengal: about ninety-five miles in length from north to south, and fifty in breadth from east to west; watered by the river Cauvery, which divides itself into several streams. Though forming a part of the Carnatic, it is governed by a prince or rajah, and pays an annual subsidy to the English of 160,000*l*. sterling.

TANJORE, a town of Hindoostan, and capital of a country to which it gives name, situated in a plain between two branches of the Cauvery; including the suburbs, about two leagues in circumference; a double wall and a large ditch are the only defence. The palace is situated to the east of the town, and is a grand square, fortified with a wall and a wet ditch, abounding in crocodiles. It was originally only a pagoda. In 1773, this city was taken by the British under general Joseph Smith; 176 miles S.E. of Seringapatam. N. lat. $10^{\circ} 46'$. E. long. $79^{\circ} 10'$.

TANIS, in *Ancient Geography*, a town of Egypt, situated between the Mendesian mouth of the Nile towards the west, and the Pelusian mouth to the east. It lay on a small branch of the Nile, and gave its name to one of the mouths of the river. This town was the capital of the nome called Tanites.

TANISTRY, TANISTRIA, an ancient municipal law, or tenure, which allotted the inheritance of lands, castles, &c. held by this tenure, to the oldest and most worthy and capable person of the deceased's name and blood, without any regard to proximity. This, in reality, was giving it to the strongest; and this naturally occasioned bloody wars in families; for which reason it was abolished under king James I.

Sir John Davies describes it thus: "Quant aucun person morust seisie des aucuns castles, manors, terres ou tenements del nature et tenure de tanistry; que donques mesmes le castles, &c. doent descendre, et de temps dont memory ne court ont use de descendre, Seniori et dignissimo viro sanguinis et cognominis de tiel person," &c.

VOL. XXXV.

TANITICUM OSTIUM, in *Ancient Geography*, the name of the sixth mouth of the Nile, in passing from the west to the east.

TANKABAT, in *Geography*. See TANTABEE.

TANKARD TURNIP, in *Agriculture*, the common English name of a particular sort of this kind of root, which has the property of standing high above the ground. It is a good sort for feeding off before the frost sets in, in the winter season; but after that has taken place, it is not so valuable or useful, as being more liable to be injured and affected by it than the other sorts, in consequence of standing exposed so much above the surface of the land. See TURNIP.

TANKERDSONG, in *Geography*, a town of Thibet; 230 miles E. of Lassa. N. lat. $29^{\circ} 50'$. E. long. 100° .

TANKESIR, a town of Persia, near the gulf; 9 miles N. of Busheer.

TANKISA, a town and fortress of Thibet, at the foot of a mountain, which is said to exhale suffocating fumes; 120 miles N.W. of Tassafudon. N. lat. $28^{\circ} 23'$. E. long. $87^{\circ} 20'$.

TANKROWAL, a town of Africa, in the kingdom of Kaen, with a factory belonging to the English African company, near the river Gambia. The Portuguese have a church there. The chief trade is in wax. N. lat. $13^{\circ} 10'$. W. long. $14^{\circ} 27'$.

TANKUNNY, a town of Hindoostan, in Berar; 20 miles W. of Ellichpour.

TANLAY, a town of France, in the department of the Yonne; 6 miles E. of Tonnerre.

TANLOCOM, a town of Mexico, in the province of Guafteca; 40 miles S.W. of St. Yago de los Valles.

TANNA, an island in the South Pacific ocean, and one of those called *New Hebrides*, discovered by captain Cook in the year 1774; about twenty-two miles in length, and ten in breadth. The inhabitants would not suffer captain Cook, or any of his company, to advance far into the island. The produce, as far as could be seen, is bread-fruit, plantains, cocoa-nuts, a fruit like a nectarine, yams, tarra, a sort of potatoe, sugar-cane, wild figs, a fruit like an orange, which is not eatable, and some other fruits and nuts. Captain Cook doubts not but nutmegs likewise grow in this island. The bread-fruit, cocoa-nut, and plantains, are neither so plentiful nor so good as at Otaheite; on the other hand, sugar-canes and yams are not only in great plenty, but of superior quality, and much larger. One of the latter weighed fifty-six pounds, every ounce of which was good; hogs did not seem to be scarce; but they saw not many fowls. These are the only domestic animals they have. Land-birds are not more numerous than at Otaheite, and the other islands; but they saw some small birds, with a very beautiful plumage, which they had never seen before. There is a great variety of trees and plants. The inhabitants of this island, as well as those of Erromango, were at first thought to be a race between the natives of the Friendly Islands and those of Mallicollo; but upon further acquaintance, it was found that they had little or no affinity to either, except in their hair, which is generally black and brown, growing to a tolerable length, and very crisp and curly. Their beards, which are strong and bristly, are generally short. One of the languages which they speak is nearly, if not exactly, the same with that of the Friendly Islands: the other, which is also that of Erromango and Annatom, is properly their own. These people are of the middle size, rather slender than otherwise; many are little, but few tall or stout; most of them have good features and agreeable countenances, are, like all

L the

the tropical race, active and nimble, and seem to excel in the use of arms, but not to be fond of labour. Both sexes are of a very dark colour, but not black; nor have they the least characteristic of the negro about them. They make themselves blacker than they really are, by painting their faces with a pigment of the colour of black lead. They also use another sort, which is red; and a third sort, brown, or a colour between red and black. All these, but especially the first, they lay on with a liberal hand, not only on the face, but on the neck, shoulders, and breast. The men wear nothing but a belt, and the wrapping-leaf, as at Mallicollo. The women have a kind of petticoat, made of the filaments of the plain-tree, flaps, or some such thing, which reaches below the knee. Both sexes wear ornaments, such as bracelets, ear-rings, necklaces, and amulets. The bracelets are chiefly worn by the men; some made of sea-shells, and others of those of the cocoa-nuts. The men also wear amulets; and those of most value being made of a greenish stone, the green stone of New Zealand is valued by them for this purpose. Necklaces are chiefly used by the women, and made mostly of shells; ear-rings are common to both sexes, and those valued most are made of tortoise-shell. These people, beside the cultivation of ground, have few other arts worth mentioning. They know how to make a coarse kind of matting, and a coarse cloth of the bark of a tree, which is chiefly used for belts. The workmanship of their canoes is very rude; and their arms, with which they take the mollusks in point of neatness, come far short of some others. Their weapons are clubs, spears, or darts, bows and arrows, and stones. The clubs are of three or four kinds, and from three to five feet long. Captain Cook knew no more of their cookery, than that it consists of roasting and baking; for they have no vessels in which water can be boiled. Nor did he know that they had any other liquor but water, and the juice of the cocoa-nut. They were utter strangers to their religion, and but little acquainted with their government. They seem to have chiefs among them, at least some were pointed out to him by that title; but they appeared to have very little authority over the rest of the people. They gave intimations that they practised circumcision, and that they allowed themselves to eat human flesh; but captain Cook says, that it admits of doubt whether they are cannibals. The island contains a very considerable volcano, and some hot springs were discovered, which raised the thermometer from 80° to 170° , and in one place to 202° . Captain Cook named the harbour where he lay, *Port Resolution*, from the name of the ship, which was the first that had ever entered it: which is situated in S. lat. $19^{\circ} 32' 25''$. E. long. $169^{\circ} 44' 35''$. The variation of the needle was $7^{\circ} 14' 12''$ E.; and the dip of its south end $45^{\circ} 23'$. The time of high water on full and change days was about $5^h 45^m$, and the tide rose and fell three feet.

TANNA, a town of Hindoostan, in the island of Salfette, on the east coast; 15 miles N.E. of Bombay. N. lat. $19^{\circ} 13'$. E. long. $72^{\circ} 53'$.

TANNA, or *Thann*, a town of Saxony, in the county of Reussen; 17 miles S.W. of Greitz. N. lat. $50^{\circ} 25'$. E. long. $11^{\circ} 57'$.

TANNA Balloo, a small island in the East-Indian sea, near the east coast of Borneo. N. lat. $4^{\circ} 52'$. E. long. $113^{\circ} 24'$.

TANNA Mera, a small island in the East-Indian sea, near the east coast of Borneo. N. lat. $3^{\circ} 45'$. E. long. $117^{\circ} 5'$.

TANNAR, a town of Bengal; 35 miles E.S.E. of Moorshedabad.

TANNAS, a town of Sweden, in Harjedalen; 15 miles N.W. of Langaichantz.

TANNASER, a town of Hindoostan, in the subah of Delhi. This place was formerly held sacred by the Hindoos. In 1011 it was taken by Mahmood, king of Gizni; 45 miles N.E. of Hissar. N. lat. $29^{\circ} 31'$. E. long. $76^{\circ} 20'$.

TANNAY, a town of France, in the department of the Nievre; 16 miles S.S.E. of Clamecy.

TANNODRE, a town of the principality of Culmbach; 8 miles S. of Culmbach.

TANNEBERG, a town of Austria; 8 miles S. of Aigen.

TANNED HIDE. See **HIDE** and **LEATHER**.

TANNENBERG, in *Geography*, a town of Prussia, in the province of Oberland; 6 miles S.S.W. of Hohenstein. —Also, a town of Saxony, in the circle of Erzgebirg; 6 miles S.W. of Wolkenstein.

TANNER, **THOMAS**, in *Biography*, an English prelate, and eminent antiquary, was the son of a clergyman, who was vicar of the parish of Market Levington, in Wiltshire, where he was born in the year 1674. He entered into Queen's college, Oxford, in 1689, and having graduated as B.A., he removed to All-Souls college in 1694, of which he became a fellow in 1696. At the university he devoted himself very much to the study of antiquities, and in 1695 published his "Notitia Monastica," or "A short Account of the religious Houses in England and Wales," which attracted notice; and soon after Dr. Moore, bishop of Norwich, appointed him his chaplain, and in 1701 made him chancellor of his diocese; which office led him to acquire an extensive and correct acquaintance with municipal and ecclesiastical law, so that he was often consulted by the dignitaries of the church. Having married the bishop's daughter, he obtained in succession various preferments; and in 1710 he took the degree of D.D. In 1723 he became canon of Christ-church, Oxford; in 1727, prolocutor of the lower house of convocation; and in 1732, bishop of St. Asaph. He died at Christ-church, in 1735, where he was buried. He was thrice married, but left only one son. He was distinguished by the exemplary discharge of his clerical functions, and by the liberality of his charities. Availing himself of papers presented to him by Wood, he published a second edition of his "Athenæ Oxonienses," much corrected and enlarged, with the addition of more than five hundred lives from the author's MS. Lond. 1721. 2 vols. fol. A posthumous work, founded on his Notitia, and entitled "Notitia Monastica; or, an Account of all the Abbies, Priors, and Houses of Friars, heretofore in England and Wales, and also of all the Colleges and Hospitals founded before 1540," was published by his brother, the Rev. John Tanner, Lond. 1744. fol. Another elaborate work, on which he had bestowed the application of forty years, entitled "Bibliotheca Britannico-Hibernica; five, de Scripturis qui in Anglia, Scotia, et Hibernia, ad sæculi xvii. initium floruerunt, literarum ordine juxta familiarum nomina dispositis Commentarius, &c." was published in 1748, fol. under the care of Dr. Wilkins, who prefixed to it a learned preface. He had also made collections for the history of his native county of Wilts, but by removal to a distance he was prevented from prosecuting his design. To the Bodleian library he bequeathed many valuable papers, tending to illustrate the history of these islands, and he made several communications of a similar nature to the Society of Antiquaries, of which he was a member. His various labours in this way rank him among the most valuable contributors to British literature and ecclesiastical history. Biog. Brit. Gen. Biog.

TANNER,

TANNER, a person who manufactures hides and skins by tanning.

It is only within a few years past, that the tanners of this country have been liberated from a variety of penalties and prohibitions, which were extremely oppressive, and long retarded the progress of the manufacture.

In the reigns of Elizabeth and James I. when *patents of monopoly* were in existence—when the true principles of trade were not well understood—and when the leather manufacture was conducted by unskilful persons, some rules and regulations as to the mode and manner of tanning, the materials to be employed, and the time to be consumed in the process, might, perhaps, be in some degree necessary: but such prohibitions and restrictions were wholly inapplicable to the present enlightened age. It was not, however, till 1808, after a long parliamentary investigation, that the act 1 James I. c. 22, and others of a similar tendency which had long disgraced our statute-book, were at length repealed by the 48 Geo. III. c. 60. By this act, the tanner is now allowed, like all other manufacturers, to exercise his ingenuity in the discovery of new materials or new methods, in abridging the time or improving the process. Nor can any injury thereby arise to the community; for the competition which in this country exists in every branch of trade, combined with the credit and the interest of the parties, will always insure to the public the production of the best articles which can be manufactured. See **LEATHER**, **TAWING**, and **VELLUM**.

TANNER's Bark, is the bark of the oak or other tree, which, after it has been ground in a mill into a coarse powder, is used in tanning of leather. When the tanning principle has been wholly exhausted, it is taken out of the pits, and called *tan*. It is then sold to the gardeners, who use it in hot-houses to produce an artificial heat, for the purpose of raising pine-apples, &c. After a certain time the tan ceases to cause fermentation: it is then taken out of the hot-house, and, when entirely rotted, becomes a vegetable mould, and is employed as a manure in kitchen-gardens and on grass-land.

With respect to its advantages as a manure, different opinions are entertained. Miller, Mortimer, and others, have represented it as highly nutritious, while more modern agriculturalists consider it of very little value. When, however, it is blended and incorporated with other vegetable substances, or with lime or earthy matter in certain proportions, cautiously employed, and laid on soon after Michaelmas, it will be found a good top-dressing for stiff and cold grass-land.

TANNETE, in *Geography*, a town on the W. coast of the island of Celebes. S. lat. 4° 14'. E. long. 120° 4'.

TANNEWANG, a river on the S. coast of the island of Celebes, which runs into the sea, 5 miles W. of Bonthain.

TANNHAUSEN. See **THANNHAUSEN**.

TANNIN, in *Vegetable Chemistry*, a peculiar substance which is naturally formed, and exists in a great number of vegetable bodies, such as oak bark, galls, fumach, catechu, &c. Its name is derived from the effect it has in converting the gelatine into leather.

Several processes have been given to obtain pure tannin, which have been so various in their results, as to induce chemists to suspect the identity of tannin.

The process recommended for procuring pure tannin, is to powder nutgalls, and make an infusion in water, which will be of a deep brown colour. Evaporate the infusion with a gentle heat till it is very strong, but still retaining its humidity. Add to this a saturated solution of carbonate of potash. A yellowish-white precipitate is formed, which is said to be

pure tannin. When the liquid part is poured off, a little cold water must be added to wash the precipitate, as a large quantity would dissolve it again. When the precipitate is separated and dried, it assumes the appearance of resin, having a vitreous fracture. It is of a brown colour. Its taste is bitter, and strongly astringent. It is very soluble in water. The solution becomes frothy by agitation, as if it contained soap. It dissolves still more plentifully in alcohol. The solution is of a dark-brown colour, differing little in its properties and appearance from what has been termed tincture of galls.

For our first knowledge of this substance in a definite state, we are indebted to Deyeux. Seguin afterwards separated it by means of a solution of gelatine, the matter which was precipitated being a substance, having the smell and many other properties of leather. These facts led to the great improvements he made in the process of tanning, of which no true theory was known before his time.

For a more minute investigation of the properties of tannin, we are indebted to Proust. He obtained his tannin by adding an acid to a concentrated infusion of nutgalls. A precipitate is obtained of the consistency of pitch. This precipitate is to be washed with a little cold water, with the same caution observed in the last process. The precipitate is now to be dissolved in boiling water, and carbonate of potash added, which takes up the acid and precipitates the tannin.

Proust recommends the following process for procuring pure tannin. Drop into an infusion of nutgalls, a solution of muriate of tin. This gives a yellow precipitate, which being separated, washed, and dried, is of a buff-colour. This is a compound of oxyd of tin and tannin. He then mixes this powder with water, and passes through it sulphuretted hydrogen gas. The sulphur combines with the tin, and becomes insoluble, while the tannin dissolves in the water. When the sulphuret is separated, and the solution of tannin evaporated with a gentle heat, a brown substance is left behind, which he considered as pure tannin.

Another process for obtaining tannin from infusion of nutgalls, has been given by Merat Guillot. This consists in mixing pure water with an infusion of galls. If to this mixture dilute nitric or muriatic acid be added, a deep brown precipitate is formed, which, when dry, becomes black. This he supposes to be pure tannin.

Trommidorff has shewn that all these processes are insufficient to produce pure tannin. As the substance called extract was contained in all the above precipitates, and more or less gallic acid, he made a great number of experiments to obtain pure tannin; and although he obtained it nearer to a state of purity than any of his predecessors, his labours were not completely successful. He evaporated the infusion of galls with a gentle heat to one-fourth its bulk. The liquid became muddy from the precipitation of extractive matter, and was separated by straining. It was now further evaporated to the consistence of jelly, and ultimately dried by a gentle heat. He now digested the mass with pure alcohol, till no more gallic acid could be taken up. He then considered the mass left behind as pure tannin, or nearly so. In order to ascertain if it still contained extract, he re-dissolved it in pure water, and evaporated this and future portions of water from it, judging that if any extract still remained it would become insoluble by oxygenation, and thus be precipitated, but no deposition took place. Suspecting it might contain mucilage, he left the solution in a warm place for some time. It became covered with mould, which he attributed to the presence of mucilage. The mould was separated by filtration, and the solution evapo-

TANNIN.

rated to dryness, which left the tannin in a state of considerable purity.

He still, however, found that it contained a portion of sulphate of lime. In order to separate this salt, he dissolved the tannin in water, to which he added carbonate of potash: this caused a precipitation, which has been already noticed. The clear liquor being separated, a solution of acetite of lead was added to it. A precipitate fell down, which consisted of tannin, combined with oxyd of lead, and probably sulphate of lead. The lime also combined with the tannin, forming an insoluble compound. He then separated this precipitate, mixed it with water, and passed a stream of sulphuretted hydrogen gas through it. The lead and sulphur became separated, and the combination of lime and tannin unchanged, while the pure tannin remained in solution, which was obtained by evaporating the separated liquid to dryness. The tannin thus obtained, approaches much nearer to purity than that obtained by any of the former processes. But we shall shew further on, that, even in this state, its purity is doubtful.

Tannin obtained by the above process does not differ much from that formed by the other processes. We have already stated it to be soluble in alcohol: when, however, both the tannin and alcohol are pure, the tannin does not dissolve.

Most of the metallic oxyds form insoluble compounds with tannin. There is, however, great reason to believe that the gallic acid, which is difficult to separate from it, has a much greater effect upon these bodies. It is supposed that when the metallic oxyds are precipitated by tannin, the latter combines with the oxygen, and, in some instances, converts the tannin into extract.

The common method of detaching the presence of tannin is by a solution of gelatine in water. Ifinglass is mostly used for this purpose. The solutions both of the tannin and the gelatine should be in a considerably concentrated state; as weak solutions of either redissolve, to a certain extent, the precipitate which the tannin forms with the gelatine.

The gelatine should be quite fresh, as the precipitate is imperfect when it has the least signs of putridity.

Sir Humphrey Davy states that the proportion of the gelatine to the water should be 120 grains of the former to 20 ounces of the latter.

According to the authority of the same chemist, the compound formed by the tannin and gelatine dried at 150°, is composed of

Gelatine	54
Tannin	46
	100

Potash, soda, and ammonia, combine with tannin, forming compounds which are less soluble in water than pure tannin. These alkalies have a stronger attraction than gelatine for tannin; as the alkaline solutions do not precipitate gelatine till the alkali is saturated by an acid.

The combinations of the earths with tannin are mostly insoluble. Those with barytes and lime are slightly so, and do not precipitate gelatine till an acid is added.

Most of the acids form insoluble compounds with tannin; but when extract is present, it is also precipitated: hence the imperfection of the process for separating tannin by acids.

When perfectly free from gallic acid it has no action upon sulphate of iron; but it produces a deep blue precipitate from the oxy-sulphate: hence its effect in common

writing-ink and black dye. The black is not complete without exposure to the air. The precipitate which the tannin forms is very heavy, and almost immediately separates from the water; while that formed by the gallic acid remains longer suspended, and certainly, on that account alone, is an essential ingredient in writing-ink.

Tannin exists in a great number of vegetables in some proportion, but is the most abundant in nutgalls; and of them, the Aleppo galls afford the most. Sir Humphrey Davy has given the following analysis of the Aleppo galls. He extracted, by infusion with water, all the soluble part from 500 grains of powdered galls. This solution he submitted to slow evaporation, from which he obtained, in solid matter, 185 grains. These he found to consist of

Tannin	130
Gallic acid, with extractive matter	31
Mucilage and matter rendered insoluble	} 12
by evaporation	
Calcareous earth and saline matter	12
	185

We are indebted to the same distinguished chemist for bringing into notice a new substance, which contains a large proportion of tannin. This substance is brought from the East Indies, and is known by the names of catechu, or terra Japonica. It is produced by the evaporation of a vegetable fusion from the wood of a species of *mimosa*, which grows in India.

There are two varieties of this substance, one brought from Bengal, and the other from Bombay. The former is of a chocolate colour, of the specific gravity 1.28; the latter of a lighter colour, of the specific gravity 1.39. Both have an astringent taste, leaving an impression of sweetness. They are not changed by exposure to the air.

Sir Humphrey procured an infusion from this substance by long decoction, the specific gravity of which was 1.102: 500 grains of this infusion yielded, by evaporation, 41 grains of solid matter; 34 of which were tannin, and 7 of a peculiar extractive matter.

This substance, in its original state, seems to contain a very large proportion of tannin. The above chemist found that 100 grains of the powdered catechu required 18 ounces of water for its infusion. The residuum, or undissolved part, is seldom more than $\frac{1}{4}$ th of the original weight, and consists of calcareous and aluminous earth, with a little fine sand: 200 grains of the Bombay catechu gave

Tannin	109
Peculiar extract	68
Mucilage	13
Of the residuum above-mentioned	10

The catechu from Bengal gave, in 200 grains,

Tannin	97
Peculiar extractive matter	73
Mucilage	16
Residual matter, consisting of lime, alu-	} 14
mine, and sand	
	200

The great uncertainty which has prevailed respecting the definite nature of tannin, seems to have been completely removed by the very important discovery made by Mr. Hatchett, who has succeeded in forming artificial tannin. An account of his experiments may be found in three papers in the *Philosophical Transactions* for 1805 and 1806.

The most direct process which is given for obtaining it, is by pouring an ounce of nitric acid, diluted with two parts of water, upon 100 grains of charcoal, in a matrass. This is to be placed in a sand-bath. Great effervescence takes place, and much nitrous gas is disengaged. At the end of two days he added a second ounce of acid, and sometimes even a third. The digestion is continued till the whole is dissolved. This solution is of a reddish-brown colour. It is then to be slowly evaporated to dryness, which produces a brown glossy substance, exhibiting a resinous fracture.

This substance has the following properties :

1. It dissolves in cold water and alcohol.
2. The flavour is highly astringent.
3. Exposed to heat, it smokes a little, swells up, and affords a bulky coal.
4. The solution in water reddens litmus paper.
5. It copiously precipitates the metallic salts, especially the muriate of tin, acetite of lead, and oxyfulphate of iron. The precipitates are commonly of a brown colour.
6. It precipitates gold in the metallic state.
7. It precipitates the earthy salts; such as the nitrates of lime, barytes, &c.

8. When the alkalies are added to this solution, the colour becomes deeper, and ultimately turbid.

9. A solution of isinglass added to the same solution produces a precipitate, which is insoluble in boiling water, resembling in its essential properties the precipitate formed by the natural tannin.

Mr. Hatchett produced the same substance by treating various kinds of coal in the same way, such as pit-coal, coke, and animal charcoal. What may seem very curious, he formed it from the coal of one portion of isinglass to precipitate another portion dissolved in water; and hence asserts that one portion of the skin of an animal may be employed to convert the other into leather.

Of the different substances employed, he found those the best which consisted of carbon unmixed with other vegetable matter, which always reduced the quantity; and that those vegetable substances which contained gum or mucilage, produced the least tannin.

When he succeeded in producing tannin from other vegetable substances, such as indigo, resin, lac, and many other bodies, it was by repeatedly adding fresh nitric acid; by which he very properly supposes that the carbon becomes separated, so as to put it under similar circumstances to the charcoal itself. Indigo produced the most in this way. At the commencement of his paper he mentions the fact of Mr. Chenevix having found that coffee-berries acquired, by roasting, a portion of tannin. He made some experiments which, although not very successful, convinced him that the chief characteristic properties of tannin may be formed or developed at some particular temperature and under favourable circumstances, by very simple means.

He ingeniously conjectures, that the tannin found in some varieties of peat has been produced in this way.

In making use of sulphuric acid to char various substances, he found that, in some instances, the artificial tannin, or a substance nearly resembling it, was formed. He first dissolved

100 grains of camphor in an ounce of concentrated sulphuric acid. The camphor first dissolved, without producing much change of colour. In a little time it became brown, and ultimately black. During this change, sulphurous acid gas was disengaged. After two days, during which time the alembic had not been heated, the disengagement of gas diminished, and the vessel was placed in a moderately heated sand-bath. This increased the action. At the end of two days, six ounces of cold water were added; the liquid changed to a reddish-brown colour; the disengagement of gas ceased, and was succeeded by a smell resembling a mixture of the oils of lavender and peppermint. By gradual distillation, the water came over impregnated strongly with the above odour, and accompanied by an essential oil, which weighed three grains.

When the whole water had come over, two ounces more were added. The smell before mentioned did not return, and the evaporation was continued to dryness. The blackish-brown residuum was not acted upon by water, but by several digestions with alcohol, leaving behind a compact coaly residuum, which, when dried and heated to a red heat in a close vessel, weighed 53 grains. The alcohol was then drawn off from the solution by distillation in a water-bath, leaving a blackish-brown mass, of the appearance of a gum resin, and the smell of calomel. Its weight was 49 grains. The whole of this therefore consisted of

The essential oil above-mentioned	3
A compact hard coal in small fragments	53
And the blackish-brown mass above-mentioned	49
	105

This increase of five grains Mr. Hatchett attributes to the oxygen united to the carbon by the acid, or the water combined with the blackish-brown substance.

This latter substance had the following properties :

1. It had an astringent taste, and when dissolved in cold water, formed a dark-brown solution.

2. It yielded a dark-brown precipitate with sulphate of iron, acetite of lead, muriate of tin, and nitrate of lime.

3. It precipitated gold in its metallic state.

4. It formed so complete a precipitate with a solution of isinglass, that the liquid became colourless as water.

The precipitate was nearly black, and was, like the other compounds of tannin and gelatine, insoluble in hot water.

Mr. Hatchett observes that although this substance possesses the general character of that obtained by the nitric acid with charcoal, yet it seems to act less powerfully upon skin. The precipitate, at the time of its formation, is more flocculent and less tenacious than that produced by the other process.

Mr. Hatchett supposes this difference may arise from the want of azote, which seems to exist in that produced by nitric acid and charcoal.

He ascertained this by subjecting to analysis a portion which had been prepared from vegetable charcoal. He exposed in a retort some of this tannin in the dry state, to the heat of a lamp connected with a jar, to obtain the gaseous product.

First a small quantity of water rose; then a little nitric acid, which had not been expelled in the evaporation. Next a small quantity of yellowish liquor, which stained the neck of the retort. The fire was then raised, when a quantity of gas was explosively disengaged, and upset the jar. This gas he judged from the smell to be ammonia. He also observed

TANNIN.

observed some white fumes, which resulted from the nitric acid uniting with the ammonia.

On replacing the jar, he continued the process. The future gas which came over was carbonic acid, and a little of another, which he supposed to be nitrogen.

Although the artificial tannin appears in almost every respect similar to the natural tannin, it might be expected that each would have been similarly affected by nitric acid, yet Mr. Hatchett found that the one was destructible by that acid, while the other was not in the least affected by it. He frequently distilled nitric acid from the artificial tannin, without producing any change upon it.

The same acid being added to infusion of galls, sumach, Pegu cutch, and kascutti, completely destroyed the tannin. The common catechu and oak bark treated in the same way, had not the whole of their tannin destroyed. He then made infusions of equal strength of nutgalls, sumach, shavings of oak wood, oak bark, and the artificial tanning substances. To half an ounce of each of these, one drachm in measure of strong nitric acid was added. The tannin of all were destroyed, with the exception of the oak bark and the artificial tannin. Mr. Hatchett observes that the tannin of those bodies containing much mucilage is the most liable to destruction by the nitric acid; and that in the cases where the tannin is destroyed, the oxalic acid is mostly formed. The oak bark and the common catechu contain little or no mucilage, and hence have less of their tannin destroyed.

These facts seem to prove that pure tannin, unmixed with other matter, is not affected by nitric acid, and that in those instances in which it is destroyed, the effect must arise from some new substance being formed by the action of the acid upon the extraneous matter, and also that mucilage contributes the most to this change.

Mr. Hatchett has not given us any precise analysis of this substance, but concludes, from its formation, that it has carbon for its base. From the circumstance of its being formed with greater facility when the nitric acid is diluted, he thinks that the water is decomposed, and that the hydrogen enters into its composition.

In the case of its decomposition by heat, the formation of ammonia led him to believe that azote was also one of its elements.

This, however, does not agree with the fact of its being formed with sulphuric acid and vegetable matter only. Although this objection seems partly to be removed by the circumstance of the tannin from sulphuric acid being different in some of its properties from that produced from the nitric acid and charcoal, it may, however, be here observed that the natural tannin, which is not known to contain azote, more nearly resembles that formed with nitric acid, than that from the sulphuric acid.

It does not appear probable that azote is a component part, even of the natural tannin. The ammonia which Mr. Hatchett obtained might be in combination with the tannin, and may perhaps always be formed when the tannin is formed. The circumstance of the tannin not being changed by repeatedly digesting it with nitric acid, would seem to favour the idea of its consisting of carbon and oxygen only. The importance of this substance in the art of tanning, ought to be a sufficient stimulus to future experiments.

If in the process of forming artificial tannin, the nitric acid is decomposed merely into nitrous gas, it might be practicable to bring it back to its original state by the oxygen of the atmosphere only, and thus produce a valuable product, which is now obtained at considerable expence from certain vegetables.

The following table shews the proportions present of natural tannin in a variety of substances.

Catechu from Bombay	-	-	-	54.5
Bengal	-	-	-	48.5
Aleppo nutgalls	-	-	-	26
Sumach	-	-	-	18
Souchong tea	-	-	-	11
Green tea	-	-	-	9.2
Leicestershire willow bark	-	-	-	7.5
Oak bark	-	-	-	6.6
Spanish chefnut bark	-	-	-	5
Elm bark	-	-	-	3
Common willow bark	-	-	-	2.5

Mr. Biggin also has published, in the Philosophical Transactions for 1799, the result of some experiments on the proportions of tannin in various kinds of bark, which nearly corresponds with the preceding statement, as will be seen by the following table, in which the *maximum* of the tanning principle is supposed to be 20.

	Tanning Principle.	
	By the Hydrometer.	Weight in Grains.
Elm	2.1	28
Oak (cut in winter)	2.1	30
Horfe chefnut	2.2	30
Beech	2.4	31
Willow (boughs)	2.4	31
Elder	3.0	41
Plum-tree	4.0	58
Willow (trunk)	4.0	52
Sycamore	4.1	53
Birch	4.1	54
Cherry-tree	4.2	59
Sallow	4.6	59
Mountain ash	4.7	60
Poplar	6.0	76
Hazel	6.3	79
Ash	6.6	82
Spanish chefnut	9.0	98
Smooth oak	9.2	104
Oak (cut in spring)	9.6	108
Huntingdon or Leicester willow	10.1	109
Sumach	16.2	158

It appears from this table that similar barks, when taken from trees at different seasons of the year, differ as to the quantities of tannin contained in them. In the winter they contain the least, and in the spring (which is the usual time of felling oak-timber), if the season is very cold and ungenial, the quantity is diminished. This is well known to practical men, as likewise that all barks contain the greatest proportion of tannin; at the time when the buds of the trees begin to germinate. It is found by experience that, on an average, four or five pounds of good oak bark are required to form one pound of leather.

Sir Humphrey Davy observes that the astringent principles in barks vary considerably, according as their age and size are different. That in every astringent bark, the interior white bark (which is the part next to the alburnum) contains the largest quantity of tannin. The proportion of extractive matter is generally greatest in the middle; but the epidermis seldom furnishes either tannin or extractive matter. The white cortical layers are, comparatively, most abundant in young trees; and hence their barks contain, in the same weight, a larger proportion of tannin than the

TANNING.

barks of old trees. (Phil. Transf. 1803, p. 264.) From these observations, founded on experiments, Mr. Hatchett infers that there is an intimate connection between the formation of new wood and the formation of tannin in such vegetables as afford the latter; and this idea is corroborated by the chemical nature of those substances.

It has been suggested that the extractive matter found in barks, or in substances used in tanning, affects the colour, if not the quality of leather. Thus, skin tanned with gall-nuts is much paler than skin tanned with oak bark, which contains a brown extractive matter. Leather made from catechu is of a reddish tint.

It is found that the precipitates obtained from infusions containing this principle or tannin by ifinglafs, when dried, contain at a medium rate about 40 *per cent.* of vegetable matter; and that it is easy to obtain the comparative value of different substances for the use of the tanner, by comparing the quantities of precipitate afforded by infusions of given weights mixed with solutions of glue or ifinglafs. In order to make experiments of this kind, an ounce or 480 grains of the vegetable substance in coarse powder, should be acted upon by half a pint of boiling water: the mixture should be frequently stirred, and suffered to stand twenty-four hours; the fluid should then be passed through a fine linen cloth, and mixed with an equal quantity of solution of gelatine, made by dissolving glue, jelly, or ifinglafs in hot water, in the proportion of a drachm of glue or ifinglafs, or six table spoons full of jelly, to a pint of water. The precipitate is to be collected by passing the mixture of the solution and infusion through folds of blotting paper, and the paper exposed to the air until its contents are quite dry. If pieces of paper of equal weights are used, in cases in which different vegetable substances are employed, the difference of the weights of the papers when dried, will indicate, with tolerable accuracy, the quantities of this principle or tannin contained in the substances, and their relative value for the purposes of manufacture.

TANNING, the art of converting the gelatinous part of the skins of animals into the substance called leather, by impregnating it with tannin or the tanning principle, in such a manner as to render it tenacious, durable, and impermeable to water.

It is difficult to say at what period the art of tanning was discovered. It was doubtless known to the ancients in some degree of perfection; and it is highly probable that the skins of animals were employed by man as a covering long before the art of tanning was known: but they would require in this state to be constantly kept dry, as moisture would soon bring them into a state of putrefaction.

The astringent matter, which converts the skin into leather, abounds in so many vegetables in every country, that accident would soon lead to some method of producing the change. Independent, however, of vegetables, many earthy and metallic substances have the property of rendering skins incorruptible to a certain extent; and some mineral waters containing copper or iron will occasion this change. Hence we may conclude that some means of giving preferation to the skins of animals must have been known at a very early period.

Though there has been no radical alteration or any great practical improvements in the art of tanning, yet for the last twenty or thirty years it has attracted the attention of many celebrated chemists and philosophers in all countries, who have investigated the subject with great accuracy and precision. Previous to this period we occasionally find some experiments and observations by men of science on the ma-

terials of tanning, as by the Hon. Charles Howard in 1674, (Phil. Transf. vol. ix.) by the abbé Nollet, Gefner, Gleditsch, Buffon, de la Lande, and others, in Mem. Acad. Sc. Paris and Berlin.

In the year 1765, the Society of Arts and Sciences in London granted a premium of 100*l.* for the discovery of a method of tanning with oak saw-dust; and in 1795 the Rev. G. Swayne suggested the use of oak leaves. It is unquestionably true that all those substances, and indeed every part of almost every vegetable in nature, possess a certain portion of the tanning principle; but, exclusive of oak bark and two or three other well-known articles, the quantities of all the rest added together would be so inconsiderable, and the proportion of tannin contained in them so inadequate to the purposes of manufacture, that, except for philosophical curiosity and chemical experiment, they are unworthy of notice. As the theories of speculative minds they are ingenious and amusing, but they afford very little useful information on the nature and properties of tannin, and have produced no beneficial results in practice.

Deyeux; about 1793, (Annales de Chimie, vol. xvii.) appears to be the first chemist who successfully explained the true principles of tanning; which afterwards, with more practical application, were still further developed by the labours of M. Seguin in 1795. Before his investigation of this subject, the theory of tanning was strictly mechanical. The astringency of vegetables, which produced the change in the skin, was considered as a resinous body, which had the effect of giving firmness to the fibres of the skin, and rendering it insoluble.

Seguin saw the operation in a chemical point of view: he examined the nature of the process scientifically, and discovered that the change which the skin underwent in the operation of tanning, was the result of a chemical union between a substance furnished by the vegetable employed, and the gelatinous part of the skin. These principles he confirmed, by combining the vegetable substance in question with the gelatine of a solution of ifinglafs.

It will be seen, from our article **TANNIN**, that the compound discovered by Seguin, and which is precipitated when an infusion of nutgalls is added to a solution of ifinglafs, is an insoluble substance, having many properties common to leather. See Nicholson's Journal, vol. i. p. 271. 4to.

The practice which M. Seguin founded upon his theory was generally admired. He first extracted the tannin from the vegetable, which was oak bark, and applied it to the prepared skin in a more concentrated form, with a view to impregnate it as speedily as possible with the tannin. This was said to be done with great success in one-third of the usual time, and to have produced superior leather. The fame of this discovery soon spread throughout Europe, and Mr. Desmond, a man of education and intelligence in this country, took out a patent for the exclusive right of using M. Seguin's method of tanning.

Although this process of suspending the hides vertically in a very strong solution of bark saved much time, yet it was soon found to be adapted only to the thickest hides used for sole leather, and quite unfit for the lighter kind of skins which required flexibility and tenacity. This method, therefore, of Seguin's, however chemical and philosophical it might appear, did not answer in the result; and as it was attended with much additional expence, has never been generally practised in England.

It was not, however, till 1803, when sir Humphrey Davy (a name ever to be recorded in the annals of science with gratitude and admiration) began to investigate the sub-

ject,

TANNING.

ject, that the art of tanning was thoroughly understood, and reduced to scientific principles. He instituted a series of experiments on the various substances employed—examined their chemical affinities and agencies—their action upon animal matter, and combination with other bodies—and developed and explained the whole with a simplicity and perspicuity which forcibly elucidated the essential principles on which the art depends. If this elucidation has not been productive of any material improvements in the mode of manufacturing leather, it may perhaps be attributed more to the prejudices arising from long habit, than to any defect in the theory and demonstrations of that enlightened philosopher. And here it may be remarked, that these demonstrations and that theory derive additional importance, and are entitled to peculiar attention, from having been strongly confirmed and successfully practised by an intelligent and respectable manufacturer (now retired from business), to whom we are chiefly indebted for this article.

From these and other sources of information now open to the public, and from the general diffusion of knowledge among all classes, the man of science and the manufacturer are daily becoming more assimilated to each other; and if the latter should be taught to discard all unfounded prejudices, and to adopt more scientific principles, there is reason to believe that the various processes of the art of tanning may yet be capable of great practical improvement.

In the two valuable papers which sir Humphrey Davy has given in the Philosophical Transactions for 1803, he considers the process of tanning as depending simply on the chemical union of the tanning principle with the matter of skin, so as to form an insoluble compound. He has shewn that Seguin's quick method of tanning is not the best; because the exterior strata of skin being perfectly combined with tannin, before the interior strata are materially acted upon, thereby prevent the latter in some degree from imbibing the full action of the solution. This renders the texture of the leather less equable, makes it harsh and brittle, liable to crack, and of course less durable.

Sir Humphrey thinks it probable that another substance, besides tannin, combines with the skin, namely, the extract, to which it owes much of its suppleness and tenacity—that the leather gets more of this substance from weak infusions of bark, than from the strong ones recommended by Seguin—that it is equally insoluble in water—and that, upon the whole, the methods now generally in use, may, with a few alterations, be considered the best.

The various discoveries pretended to have been made, and the numerous patents obtained for their use and application, have hitherto tended very little to the advancement of science or the progress of the art. This may fairly be inferred from the conclusion of the celebrated chemist above-mentioned. Indeed it appears by the specifications annexed to the patents, that most of these projected improvements purport to be either for the different construction and arrangement of the various pits—for the application of mechanical apparatus to diminish labour—or for extracting the tannin and warming the infusion by artificial heat, with a view to accelerate the process. These fancied improvements are only the idle theories and visionary projects of speculative minds: but as it may afford information to the curious, and furnish hints for future discovery, we subjoin

A List of Patents for Tanning.

1790. Anthony Fay, esq. of London, for a mechanical apparatus to diminish the labour of *handling*; to grind the

bark very small, and to concentrate it, by boiling, into a strong extract.

1794. Samuel Ashton of Sheffield, for tanning hides and skins with certain mineral productions. As such materials were prohibited by the statute of James I. an act of parliament was passed to legalize the use of them.

1795. Mr. Tucker of Wickham, Hants, for triple pits composed of wood, metal, and bricks, to keep up a constant fire at the bottom, to warm the infusion and expedite the process.

1796. William Desmond, esq. of London, for a new mode of tanning, according to M. Seguin's method, as before stated.

1797. Robert Crofs of Lancaster, for pits on a new construction, to enable him to apply artificial heat and to tan quickly.

1799. Francis Brewin, esq. of London, for a peculiar construction and arrangement of pits, and for the use of machinery, &c.

1802. John Lawrence, for the use of oak saw-dust in tanning.

1802. Thomas Martin of London, for constructing pits on a new plan, &c.

1802. John Cant and John Miller of Montrose, for boiling the bark, &c. so as to extract the tanning principle more ~~effectually~~.

1807. Robert John Stanley of Lincolnshire, for tanning light leather without bark, for a peculiar preparation previous to the application of ooze, and for boiling the materials of tanning.

1813. Sparks Moline, for the use of the solid extract of bark.

1815. Thomas Ashmore, esq. for the use of all kinds of foot, whether from coal, wood, peat, or bones, and the oils and empyreumatic liquors arising from them by distillation or combustion, to be applied to the purposes of tanning.

Of the utility of the last-named patent, we shall give no opinion at present; but of the remainder it may be affirmed that none of the methods therein recommended have ever been much practised: some of them which were adopted by a few individuals, were attended with considerable loss; and as most of them are now laid aside, we may reasonably conclude that they have not proved beneficial to the projectors or to the public.

Before we describe the present method, it may be necessary to premise, that in different parts of the kingdom, the same terms and denominations are sometimes employed to designate distinct kinds of leather: but all tanned leather is technically classed and universally known under two general denominations; namely, *hides* and *skins*. The former term being commonly applied to the larger animals, as bulls, oxen, cows, &c. which are chiefly intended for the soles of stout shoes, and other purposes requiring very thick and solid leather; while the latter term is used for calves, seals, &c. which, being thinner and more flexible, are intended for the upper leathers of shoes and boots, for saddles, harness, &c.

The heaviest and stoutest of the bull and ox hides are generally selected to make what are technically called *butts* or *backs*, and are manufactured in the following manner.

When the horns, &c. have been removed, the raw hides are laid on a heap for two or three days, and are then suspended on poles in a close room, called a smoke-house, which is heated somewhat above the common temperature by a smouldering fire: this occasions incipient putrefaction, which

which loosens the epidermis, and renders the hair and other extraneous matter easy of separation from the true skin. This is effected by extending the hide on a wooden horse or beam of a convex form, and scraping it with a large two-handled knife, called a *fleshing-knife*, which is bent, to suit the convexity of the beam.

The hides are then immersed in a pit containing water slightly impregnated with sulphuric acid. This operation, which is called *raising*, by distending the pores and swelling the fibres, prepares the hide for the reception of the tannin, and renders it more susceptible of its action.

When the hides are sufficiently *raised*, they are removed into a pit, in which they are lain smooth with a stratum of oak bark ground to a coarse powder between each.

The pit is then filled with the tanning lixivium or ooze, prepared from oak bark and water, and the hides remain a month or six weeks without being moved. At the end of this time, the tanning principle being exhausted, the ooze and spent bark are taken out of the pit, and the hides put in again, stratified with fresh bark, and covered with fresh ooze as before. Here they remain about three months, when the same process is repeated, at about the same intervals, three several times or more, according to the strength of the lixivium and the substance of the hides. When sufficiently tanned, they are taken out of the pit, hung up in a shed to dry gradually, and being compressed with a steel instrument, and beaten smooth to render them firm and dense, the operation is complete; and having been numbered, weighed, and stamped by the excise officer, to ascertain the amount, and denote the payment of the duty (which will be noticed at the end of this article), they are ready for sale, and are termed *butts* or *backs*. These form the thickest and most substantial sole leather for very strong shoes, and are chiefly intended for exportation.

Crop hides are thus manufactured. The horns having been removed, the hides are immersed in pits containing a mixture of lime and water, where they remain three or four days, being occasionally moved up and down, that each part may be uniformly exposed to the action of the lime-water. They are then taken out of the lime-pits, and the hair and other extraneous matter being scraped off on a wooden beam, as before described, are washed in water, to free them from the lime and filth adhering. They are now immersed in a weak ooze, and by degrees are removed into other pits, containing solutions gradually increasing in strength, during which time they are taken up and put down (technically termed *handling*) at least once in every day, that all parts of the hide may be acted upon by the tanning principle equally and uniformly. This is continued for about a month or six weeks, when they are put into other pits with stronger ooze and a small portion of ground bark; from whence, as the tannin becomes exhausted, they are removed to other pits in regular succession, with fresh ooze and fresh bark, for two or three months.

At the end of this period, the hides are put into larger vats, called *layers*, in which they are stratified, or lain smooth, in a lixivium of greater strength, and with a larger quantity of ground bark between each fold. Here they remain about six weeks, when they are taken up and relaid in the same manner, with fresh bark and strong ooze, for two months. This process is repeated, with little variation, once, twice, or thrice, at the discretion of the manufacturer, till the hides are thoroughly tanned; when they are taken out of the pits, suspended on poles to dry, and being compressed and smoothed, nearly in the manner before described, are called *crop hides*, and form the principal part of the sole leather which is used in England.

VOL. XXXV.

The process of tanning *skins* (calves, seals, &c.) is somewhat different from *hides*. They are continued in the lime-pits for ten or fifteen days; they are then depilated and washed in water, after which they are immersed in an infusion of pigeon's dung, called a *grainer*, having the property of an alkali. Here they remain for a week or ten days, according to the state of the atmosphere and other circumstances, during which time they are frequently *handled*, and scraped on both sides upon a convex wooden beam. This scraping, or *working*, as it is termed, with the action of the *grainer*, helps to discharge all the lime, oil, and saponaceous matter, and renders the skin soft and pliant, fitted to imbibe the tanning principle. They are now removed into pits containing a weak solution of bark, where they undergo nearly the same process of handling, &c. as *crop hides*; but they are seldom stratified in *layers*; and the time occupied in tanning them is usually from two to four months, according to their nature and substance. The skins are then dried, and sold to the currier, who dresses and blacks them for the upper leathers of boots and shoes, for harness, and various other purposes.

The light and thin sort of cow-hides and horse-hides undergo nearly the same process in tanning as calf-skins, and are applied to similar uses.

These processes are such as are now commonly practised, varying, however, with the nature and condition of the peculiar kind of hides and skins—with local habits and circumstances—and with the skill and experience of the manufacturer. The greatest defect in the common methods appears to exist in the means of extracting the tannin from the bark. Cold water is chiefly used for that purpose; but some persons conceiving that this does not entirely exhaust the tanning principle, subject the bark, as before observed, to the action of boiling water, &c. If, however, as Sir Humphrey Davy has stated, the extract as well as the tannin combines with the skin, the extraction of the tannin by heat would tend to oxygenate the former, and render it insoluble in the liquid.

The late ingenious Dr. Macbride of Dublin invented and published in 1778 a new method of tanning, the leading feature of which was the use of lime-water, which he conceived would extract the virtues of oak bark more completely than plain water.

It has, however, been observed, that both natural and artificial tannin form compounds with the alkalies and the alkaline earths, and these compounds are not decomposable by skin. Lime forms with tannin a compound not soluble in water, and therefore Dr. Macbride's system is founded on erroneous principles, as so much of the tannin as combined with the lime contained in the water was lost. It was also found, by the practical experience of tanners, that this method was in all respects injurious rather than beneficial; and as it has long been universally rejected, it is not necessary to enter into the detail. The reader who is desirous of further information on this point, may refer to Phil. Trans. vol. lxxviii. part i. art. 8.

The application of some new and cheap substitute for oak bark has been long a desideratum in tanning. Catechu, the substance we have spoken of under the article TANNIN, has been recommended, and its powerful tanning properties have been fully ascertained by experiment and actual practice: but it is not likely that the article can be procured in sufficient quantity, or at an adequate price, for the purposes of manufacture. The bark of elm, willow, larch, and other trees, together with *vallonia* (the acorn of a peculiar species of oak in Turkey), have all been employed in tanning with considerable effect.

The greatest hope which chemical science presents, is the

probability that the tanning principle will, at some future period, be formed artificially in such quantities and at such expense as will admit of its general application to practical purposes. The important discovery of Mr. Hatchett already goes far towards the accomplishment of this object. He has distinctly ascertained that a substance very analogous to tannin may be produced by exposing carbonaceous matter, whether vegetable, animal, or mineral, to the action of nitric acid; and has actually converted skin into leather by deal saw-dust, asphaltum, pit-coal, wax-candle, and even by a part of the same sort of skin itself. The changes produced in these bodies, by disuniting and recombining their elementary principles, may by further development lead to a more economical process of tanning, and thus render essential service to the arts and manufactures.

Tanned leather is subject to a very heavy excise duty. In the ninth year of queen Anne, a duty of *1d. per lb.* was laid on all hides and skins tanned in Great Britain. In the following year an additional $\frac{1}{2}d.$ *per lb.* was imposed. Thus it remained, amidst all the financial difficulties of successive chancellors of the exchequer, till 1812, when, by the act 52 Geo. III. c. 94. a further duty of $1\frac{1}{2}d.$ *per lb.* was added, making the whole duty on tanned hides and skins *3d. per lb.* The annual revenue arising therefrom now amounts to upwards of 500,000*l.*

It may not be improper here to remark, that the excise duty on leather tanned in Ireland, is levied and collected in a different manner.

The act 40 Geo. III. c. 9. passed in Ireland in 1800, instead of imposing a certain duty *per pound weight*, as in England, on all hides and skins tanned with oak bark, imposes a duty of nine pence by the year, for every cubic foot contained in all the pits in the yard of the tanner, allowing a deduction of two-ninths for certain pits called *latches*, which are used solely for the purpose of preparing the *lixivium* or *ooze*. By this act the tanner was permitted, on giving certain notice, to discontinue not less than one-fourth, and by 43 Geo. III. c. 97. not less than one-eighth for six months, receiving a proportionate deduction from his monthly payments of the duty. By the 48 Geo. III. c. 62. those acts were made perpetual.

Previous to the passing the Irish act 40 Geo. III. the writer of this article was consulted by the then chancellor of the exchequer in Ireland, on the relative amount of the intended duty of nine pence *per cubic foot*; and upon accurate calculation it was found to bear a fair proportion to the duty then existing in England. If the present duty on leather tanned in this part of the united kingdom were proportionably commuted on a similar plan, it would materially tend to the progress of the manufacture.

The chief obstacle to great practical improvement is the excise duty—not so much from its amount (though that is very considerable), as from the mode in which it is now levied and ascertained, namely, by weight, when the leather is dry and fit for sale. This mode necessarily requires a system of rules and regulations, which, from their multiplicity and complicated nature, subject the manufacturer to daily inconvenience, and to occasional hardships. For, notwithstanding the repeal of the oppressive act 1 James I. cap. 22, and other subsequent statutes, the tanner is still restricted, by various excise laws, from advantageously shaving and reducing his hides and skins—from mixing and removing them at his discretion—and also from exercising the trades of a currier, &c.

Those restrictions, it must be acknowledged, are in some degree necessary for the protection and security of the revenue, while the duties are imposed and collected upon the present

system. But if a different mode of taxation and collection (as in Ireland, on the admeasurement of the pits; or on the raw material, or any other plan) could be adopted, the benefits which would result, both to the manufacturer and to the community, are incalculable. It would leave the tanner at full liberty to conduct his business entirely according to his skill and judgment, and to unite with it the trades of currier and leather-cutter, which are so naturally connected with his own. It would enable him to facilitate the process; to save much superfluous labour; to economize the materials of tanning, which are now unavoidably wasted on useless or inferior leather; to shave, divide, select, and appropriate certain hides and skins, or parts of hides and skins, at the proper time for their peculiar purposes; to prevent the injury which leather often receives in drying at particular seasons; and ultimately to improve the quality and reduce the price of one of the most useful articles of general consumption.

These are matters well worthy the consideration of the executive government and the legislature. Some attention has already been given to this subject by the house of commons in the sessions of 1815 and 1816, and we have no doubt that by further investigation, intelligent and unprejudiced persons might easily arrange and complete a plan which would afford perfect security to the revenue, would simplify the collection, would prevent the possibility of fraud, and at the same time prove extremely beneficial to the manufacture and to the public.

TANNRODA, in *Geography*, a town of the principality of Weimar; 9 miles S.S.W. of Weimar.

TANORE, a town of Hindoostan, in the country of Calicut; 25 miles S.S.E. of Calicut. N. lat. $10^{\circ} 58'$. E. long. $75^{\circ} 54'$.

TANOS, in *Ancient Geography*, a town of the island of Crete.

TANOT, in *Geography*, a river of North Wales, which rises in the county of Montgomery, and runs into the Severn, 7 miles below Welshpool.

TANOUMDAIN, a town of the Birman empire; 30 miles N.E. of Pagahm.

TANREC, in *Zoology*, a name given by Buffon to the *ERINACEUS Ecaudatus*; which see.

TANSA, in *Geography*, a branch of the river Mobile.

TANSCHA. See TANGIA.

TANSE, a town of Brasil, in the jurisdiction of St. Paul.

TANSIFT, or TENSIFT, vulgarly called Wed Marakosh, or the river of Morocco, because it passes through the district of that name, a river that rises in mount Atlas, E. of Morocco, and taking its course about five miles N. of that city, proceeds through the territory of Morocco, and Rahamana, and nearly divides the two maritime provinces of Shedma and Abda; discharging itself into the Atlantic ocean, about 16 miles S. of the town of Saffy. In its course it receives some tributary streams issuing from the Atlas, the principal of which is the Wed Niffis. In many places it is very deep; and about six miles from Morocco it is crossed by a bridge, erected by Muley El Manfor, which is very strong, but flat, with many arches. At the mouth of this river, on the N. side, amid some sands and marshes, are the ruins of a small town, called by the Moors Suera, from which the insalubrity of the air, or the inundations of the Tanfif, have driven the inhabitants. On the other side of the river, which is passed by fording, or on rafts made of reeds tied to leathern bags inflated with wind, is a square castle, built in the reign of Muley Ishmael, to defend the passage of the river, during the time of the intestine disturbances of the empire. This castle at present only contains a few families; and the country round it is uncultivated.

TANSILLO, **Luigi**, in *Biography*, an Italian poet, was a native of Nola, and born about the year 1510. The first specimen of his talents in Tuscan poetry, when he was twenty-four years of age, was his "Il Vandemmiatore," first printed in 1734, and it afterwards passed through several editions, under the title of "Stanze amorose sopra gli orte della Donne." This poem was succeeded by another of the same licentious character, entitled "Stanze in lode della Menta." His reputation was so much sunk by these publications, that all his poems and other pieces were consigned by pope Paul IV. to the list of prohibited books. The author, deeply mortified by this circumstance, addressed a penitential letter to the pope, supplicating forgiveness, and informing him that he had made reparation by composing a devout poem, entitled "Le Lagrime di San Pietro," or, "The Tears of St. Peter." The apology was admitted, and his name was erased from the list. In 1569 he was judge-royal at Gæta, and being then declining in health, he probably did not long survive. His "Tears of St. Peter" was published, after his death, in fifteen cantos, and much applauded. It was translated into French by Malherbe, and also into Spanish. His other poems have been often printed; but the most complete edition is that of Venice in 1738. Two other elegant poems, entitled "La Balia" and "Il Podera," were published in the year 1767 and 1769. Some persons have represented Tansillo as equal to Petrarch; but though this degree of praise should not be allowed, he is considered by the best judges as one of the most elegant and spirited poets of his age. Moreri. Gen. Biog.

TANSITARO, in *Geography*, a town of Mexico, in the province of Mechoacan.

TANSOR, a town of Africa, in the kingdom of Fez, 30 miles N. of Fez.

TANSOU, a town on the E. coast of Madagascar. S. lat. 15° 40'. E. long. 50° 8'.

TANSUCHE, a town of Mexico, in the province of Guafteca; 83 miles N.W. of Panuco.

TANSY, or **TANZY**, in *Botany*. See **TANACETUM**.

TANSY, in the *Materia Medica*. The leaves and flowers of tansy have a strong, not very disagreeable smell, and a bitter somewhat aromatic taste. They give out their virtue both to water and spirit, but most perfectly to the latter: the tincture made from the leaves is of a fine green; from the flowers, of a bright pale yellow colour. Distilled with water, they yield a greenish-yellow essential oil, smelling strongly of the herb, and probably containing camphor; the remaining decoction, inspissated, affords a strong, bitter, balsaline extract.

According to Bergius, the virtues of tansy are tonic, stomachic, anthelmintic, emmenagogue, and resolvent, qualities usually attributed to bitters of the warm or aromatic kind. Tansy has been much used as a vermifuge, and its efficacy has been ascertained by the testimonies of many respectable physicians.

The seeds have been chiefly recommended in this last intention, and substituted for those of the *santonicum*, from which they differ not a little in quality as well as in appearance, being much less bitter, and of a more aromatic flavour.

Dr. Clark informs us (*Ess. and Obs. Phys. and Lit.* vol. iii.) that in Scotland tansy was found to be very beneficial in various cases of gout, and Dr. Cullen says, that he has known several who have taken it without any advantage, and some others who reported that they had been relieved from the frequency of their gout. Tansy is also recommended in the hysteria, especially when this disease is supposed to proceed from menstrual obstructions.

The leaves of this plant may be given in powder to the quantity of ʒj to ʒj, for a dose twice a day; but it has been more commonly taken in infusion, or drunk as tea. It is now scarcely ever used, except as an anthelmintic for expelling lumbrici, to which it has certainly some pretensions. Lewis. Woodville. Thomson.

TANSY, *Wild.* See **CINQUEFOIL**.

TANT, in *Natural History*, an English name for a small spider of the *phalangium* kind, having only two eyes, and eight very long legs, and commonly supposed to be very poisonous.

It is all over of an elegant scarlet colour, resembling that of the flowers of the red poppy when full blown, except that the belly has a whitish cast. Four of its legs are inserted in the upper part of the breast, and the other four near the belly; and near the origin of each leg there is a small black spot. Its body is round and full, and it is all over covered with a fine, short, velvety down. It is not unfrequent in dry pastures in the spring-season. It is terribly dreaded by our farmers, who suppose that an ox will die who chances to swallow it. Ray's Hist. Insects, p. 44.

TANTABEE, or **TANKABAST**, or *Lop*, in *Geography*, a town of Little Bucharia, on the river Yarkan; 100 miles S. of Tourfan.

TANTALAM. See **LIGOR**.

TANTALITE, in *Mineralogy*, the ore of a newly discovered metal called tantalum, or tantalum. (See **TANTALIUM**.) This ore has been called columbite by Mr. Hatchett, who obtained a specimen of it from Massachusetts bay, in North America, and discovered the metal which he denominated columbium, and which is now found to be the same with tantalum. The colour of tantalite is iron-black, sometimes with a tinge of blue. It occurs imbedded in angular pieces, from the size of a pea to that of an hazle-nut. It is also crystallized in acute octohedrons, with square bases. The surface of the angular pieces is uneven; that of the crystals is sometimes smooth, and sometimes streaked; it has a shining metallic lustre, inclining to resinous. The fracture is uneven and granular, inclining to compact or conchoidal. The fragments are irregular, sharp, and angular. It scratches glass, and gives a few sparks with steel. The streak is dull, and the powder a brownish-black. The specific gravity varies from 7.15 to 7.953. The columbite, according to Hatchett, is 5.918. Tantalite is infusible before the blow-pipe, without addition; and it suffers no change but a diminution of lustre.

The constituent parts of tantalite from Finland are, according to

	Wollaston.	Vauquelin.	Klaproth.	Berzelius.
Oxyd of tantalium	85	83	88	83.2
Oxyd of iron	10	12	10	7.2
Oxyd of manganese	4	8	2	7.4
Oxyd of tin	- 0	0	0	0.6

The North American columbite contained, according to an analysis of Dr. Wollaston, 80 parts of oxyd of tantalium, 15 of oxyd of iron, and 5 of oxyd of manganese.

Tantalite occurs in the parish of Kemito, in Finland, disseminated in coarse red granite. It bears a considerable resemblance to several other minerals, particularly to magnetic iron-stone, tin-stone, wolfram, yttryotantalite, and gadolinite. It is distinguished from magnetic iron-stone by its greater specific gravity, and by not affecting the magnetic needle; from compact black tin-stone, by its metallic lustre, and by the action of the blow-pipe, which reduces tin-stone on charcoal; from wolfram, by the absence of the foliated fracture; from yttryotantalite, by the form of the

crystals, and by resisting the action of the blow-pipe, by which yttriotantalite is melted into a greenish-yellow slag; lastly, tantalite is distinguished from gadolinite, by its greater specific gravity, uneven fracture, and infusibility. Yttriotantalite was discovered by Berzelius, in the year 1802, in a new discovered earth called yttria, from Ytterby, near Roslagen, in Sweden, where it was first discovered. See TANTALIUM and YTTRIOTANTALITE.

TANTALIUM, or TANTALUM, the metal obtained from tantalite and yttriotantalite. The method of reduction consists in boiling the ores with alkalies, and adding nitro-muriatic acid to the solution. The oxyd of tantalium is thrown down in white powder: this must be washed, dried, and strongly ignited in a crucible lined with charcoal.

Berzelius pressed the oxyd into a cavity of the size of a goose-quill, made in a lump of well-burned charcoal, and exposed it to a violent heat, in a Hessian crucible. The reduced metal was not melted, but the particles of it firmly adhered together, and formed a mass, through which water would not penetrate. The grains were hard enough to scratch glass. The specific gravity, as ascertained by Dr. Wollaston, was 5.61; but as the mass had not been melted, the weight of tantalium must be something heavier. Its colour is dark grey; and when scratched with a knife, it assumes the metallic lustre, and has the appearance of iron. It may be reduced to powder by trituration; the powder is of a dark brown colour, without the smallest metallic lustre. This powder is not in the least altered by muriatic or nitric acids, nor by aqua regia, though it be digested with them for several days. In this respect it agrees with chromium, titanium, osmium, iridium, and rhodium.

When heated to redness, it takes fire, burns feebly without flame, and goes out directly if it be removed from the fire. By this means it is converted into a greyish-white matter, which may again be reduced to the metallic state by heating it with charcoal: 100 parts of tantalium, treated in this manner, combine with 8.5 or 4.5 of oxygen. But by this process it is scarcely possible to oxydize tantalium completely.

If tantalium, when pulverized, is mixed with nitre, and thrown into a red-hot crucible, a feeble detonation takes place. The mass is snow-white, and is a compound of potash and oxyd of tantalium.

The mean of four experiments on the reduction of the oxyd of tantalium to the metallic state, makes it a compound of 100 metal with 5.485 oxygen. The supposition that the oxygen in the water, which converts the oxyd into a hydrate, is twice as great as that in the oxyd, would make it a compound of 100 metal with 5.5 oxygen. Muriatic acid throws down oxyd of tantalium, from its combinations with potash; it is then a hydrate of a white colour; and when washed and dried, it is composed of 100 of oxyd of tantalium and 12.5 water. From experiments of Berzelius, it appears that the oxyd of tantalium possesses acid properties. He succeeded in alloying several metals with tantalium, as tungsten and iron. Thomson's *Annals*, September, 1816, p. 233.

TANTALUS, in *Ancient Geography*, a town in the isle of Lesbos.—Also, a town in Asia Minor, upon the bank of the Meander.

TANTALUS, one of the many names given by chemists to mercury.

TANTALUS, in *Mythology*, a king of Lydia, Phrygia, or Paphlagonia, according to some, but, according to others, the son of Jupiter by the nymph Plota, who is said to have presented the mangled members of his son Pelops, whom he murdered, to the gods, at a feast, in order to prove their divinity; or, according to the modern explication of this fable, he offered up his son as a sacrifice to the gods.

Others, however, have charged him with revealing the secrets of the gods, *i. e.* the mysteries of their worship, of which he was the high-priest. But whatever was the nature of his crime, the poets represent him as condemned to hell, and tormented there with perpetual hunger and thirst in the midst of plenty of both meat and drink. Some represent him as standing up to the chin in water, which he was incapable of reaching; or as standing under a tree, some of the branches of which, loaded with the finest ripe fruits, hung down just before his mouth, which, the moment he endeavoured to take, always waved out of his reach. Others represent him as standing under a heavy stone, which was suspended over his head, and which he suspected would every moment fall and crush him.

Horace (lib. i. sat. i. v. 71.) seems to make Tantalus only an emblem of the covetous: as Lucretius (lib. iii. v. 1015.) makes Sisyphus, who is represented as bending under the weight of a great stone, or labouring to heave it against the side of a steep mountain, and which always rolls precipitately down again before he can fix it on the top, as an emblem of the ambitious.

TANTALUS, in *Ornithology*, a genus of the order of Grallæ. Its characters are, that the bill is long, thick at the base, and somewhat incurvated; the face naked; the tongue short and broad; the nostrils linear; and the feet, with four toes, palmated at the base. Linnæus enumerates twenty-one

Species.

LOCULATOR. With a blueish face, reddish bill, quills and tail-feathers black, and white body: the curicaca of Marcgrave, the wood peccan of Catesby, and wood ibis of Pennant. It is found in New Holland and South America.

FALCINELLUS. With a black face, blueish legs, wings and tail violet, and chestnut body: the bay ibis of Pennant and Latham, and green courlis of Buffon. A variety is the numenius castaneus of Brisson. It is found in flocks about the lakes of Italy, south of Germany, Denmark, the Ural desert, and the Caspian and Euxine seas.

MINUTUS. With face, bill, and legs greenish, ferruginous body, beneath white: the lesser ibis of Edwards and Latham. Found in Surinam.

IBIS. With red face, luteous bill, grey legs, black quill-feathers, and reddish-white body: the Egyptian ibis of Latham. Found plentifully in Egypt. See IBIS.

RUBER. With face, bill, and legs red, sanguineous body, and the apices of the wings black: the guana of Marcgrave, Willughby, Ray, &c. and the scarlet ibis of Pennant and Latham. Found gregarious in the Bahama islands, in parts of America between the tropics, particularly East Florida.

ALBUS. With red face, bill, and legs, white body, and the tips of the wings green: the white curlew of Catesby, and white ibis of Pennant and Latham. Found in the Brazils and in Carolina.

FUSCUS. With red face, bill, and legs, brown body, beneath white: the brown curlew of Ibis, and brown ibis of Pennant and Latham. Found in the warmer parts of America, and in summer in Carolina.

VRIDIS. With black face and legs, green and cyaneous wings, neck cinereous-black, beneath fasciated with white, upper part of the body and tail green-golden, beneath and rump brown-blackish: the green ibis of Latham.

IGNEUS. With black head and neck, green legs, body cyaneous, resplendent with green, beneath blackish-red, with the quills and tail-feathers green-golden: the glossy ibis of Latham.

LEUCO-

LEUCOCEPHALUS. With white head, neck, and body, bill and face yellow, legs pale, and rump with very long rufous feathers: the white-headed ibis of Latham. Found in Ceylon.

CALVUS. With white head, the hinder part of the neck tuberculated, with the jugular bag bare, the crown, bill, and legs black, and body black: the bald ibis of Latham. Found in the western parts of Africa.

MANILLENSIS. With the bill and orbits greenish, legs vermilion-coloured, and body red-brown: the Manilla ibis of Latham. Found in the island of Luçon.

CRISTATUS. With pale face, head, part of the neck, tail, and vent black, the crest on the hinder part of the head long with feathers partly white and partly black, ferruginous body, and whitish wings: the crested ibis of Latham. Found in Madagascar.

NIGER. With face, bill, and legs red, and black body: the black ibis of Latham. Found in Egypt, near Damietta.

COCO. With face and bill yellow-fleshy, legs fleshy pale, body white, wings as far as the apex white, the three outer quill-feathers black above at the apex. Found in the Caribbee islands.

PILLUS. With face, bill, and legs brown, body white, quill and tail-feathers black. Found near the rivers and lakes of Chili.

CAYENNENSIS. With face obscurely reddish, obscure bill, body black and shining green: the Cayenne ibis of Latham.

MEXICANUS. With blueish bill, reddish face, head and neck obscure and white, a little varied with green and yellow, back, rump, and legs black, breast and abdomen brown, tail and quill-feathers brassy-green: the acalotl of Ray and Willughby, the acalot of Buffon, and the Mexican ibis of Latham. Found near the lakes of New Spain.

MELANOPIS. With bill, face, and nails black, crown yellow, neck and breast yellowish, the feathers of the back, the scapulars, and tail-feathers, and pectoral band, cinereous, brown at the margin, the eyes and tail green and black, and the legs red: the black-faced ibis of Latham.

ALBICOLLIS. With black bill, head and neck rufous-white, body brown with grey waves and shining green, and red legs: the white-necked ibis of Latham. Found in Cayenne.

GRISEUS. With spadiceous bill, face and nails black, hind part of the head and neck grey, body whitish, back, rump, quills, and tail greenish-black, and reddish legs: the grey ibis of Latham, and matuiti of Willughby and Buffon. Found in Brasil.

TANTALUS'S Cup, in *Hydraulics*, is a cup, as A (*Pl. VIII. Hydraulics, fig. 6.*) with a hole in the bottom, and the longer leg of the siphon B C E D cemented into the hole; so that the end D of the shorter leg D E, may almost touch the bottom of the cup within. Then, if water be poured into this cup, it will rise in the shorter by its upward pressure, extruding the air before it through the longer leg; and when the cup is filled above the bend of the siphon at F, the pressure of the water in the cup will force it over the bend of the siphon; and it will descend in the longer leg C B G, and even through the bottom, until the cup be emptied. The legs of this siphon are almost close together, and it is sometimes concealed by a small hollow statue, or figure of a man placed over it; the bend F being within the neck of the figure as high as the chin. So that poor thirsty Tantalus stands up to the chin in water, according to the fable, imagining it will rise a little higher, and he may drink; but, instead of that, when the water comes up to his chin, it immediately begins to descend, and therefore, as he cannot

floop to follow it, he is left as much tormented with thirst as ever.

TANTAMOUNT, something that amounts to, or is equivalent to, some other.

TANTANEH, in *Geography*, a mountain of Africa, which forms the south boundary of Berdoa.

TAN-TCHING, a town of Corea; 33 miles W.S.W. of Tin-tcheou.

TANTECO, a town of Mexico, in the province of Guafteca; 25 miles N. of Panuco.

TAN-THOU-TCHING, a town on the W. coast of the island of Formosa. N. lat. 25° 8'. E. long. 120° 49'.

TANTRA, the name of a branch of literature among the Hindoos, of which we have hitherto received but very imperfect information. The books bearing this title appear to contain directions for certain religious usages adopted by some sects and condemned by others. (See **ŚAKTA**.) The name Tantra, or Yantra, is also given to mysterious hieroglyphics, sacred to particular deities. See **MANTRA**, **YANTRA**, and **PARUSHA**.

TANTUM DECIES. See **DECIES**.

TANTUMQUERI, in *Geography*, a town of Africa, in the country of Fantin, on the Gold Coast, with two forts, one belonging to the English, the other to the Dutch. N. lat. 5° 20'. W. long. 2° 54'.

TANTUR. See **TORTURA**.

TANUM, a town of Sweden, in West Gothland; 31 miles N.W. of Uddevalla.

TANUO, a town of Peru, in the archbishopric of Lima, and jurisdiction of Cagnete.

TANURI, a town of Sweden, in the government of Bahus; 30 miles N.N.W. of Uddevalla.

TANUS, in *Ancient Geography*, a river of Greece, in the Peloponnesus, which had its source in mount Paron, traversed the Argolide, and discharged itself into the gulf of Thyra.

TANXIPA, in *Geography*, a town of Mexico, in the province of Guafteca, at the foot of a mountain; 70 miles N.N.W. of Panuco.

TANYGONG, a town of Hindoostan, in Berar; 36 miles W. of Nagpour.

TANZIPAO, a river of Louisiana, which runs into Pontchartrain lake, N. lat. 30° 18'. W. long. 90° 10'.

TANZU, a town of Africa, in Angola, near the coast; 20 miles S.W. of Loando.

TANZY, in *Botany*, &c. See **TANACETUM** and **TANSY**.

TAOCE, in *Ancient Geography*, a town of Asia, in the interior of the Perside, near the town of Orebatis.—Also, a promontory of Asia, on the coast of the Perside, 500 stadia from the mouth of the river Oroatis, and 700 stadia from that of the river Rhogomagus.

TAOCENA, a country of Asia, in the Perside.

TAOCHI, a people of Asia, in the mountains of Armenia.

TAO-LOU-SAC, or **TA**, in *Geography*, a town of Lower Canada. N. lat. 48° 5'. W. long. 69° 30'.

TAONABO, in *Botany*. See **TONABEA** and **TERNSTROMIA**.

TAONEROA, in *Geography*. See **POVERTY Bay**.

TAOO ISLAND, one of the Friendly islands, in the South Pacific ocean, about 24 miles in circumference.

TAOOK, a town of Curdistan, situated in a barren country, N. of an extensive vale, which is about 20 miles over, and has a chain of mountains on each side, running E. and W.

TAORMINA, the ancient *Tauromenium*, a town of Sicily, in the valley of Demona, situated on the E. coast,

on a narrow level above a precipice of mount Taurus, and overhung by immense masses of rocks. According to Swinburne it contains 3000 inhabitants. It has been much celebrated for its costly marble and excellent wine. The ancient Tauromenium was much more extensive than the present town, and comprehended within its walls the town of the promontory of St. Andrew, where was a theatre placed between two high rocks, and commanding a full view both of *Ætna* and of the plains. This theatre is reckoned the most beautiful monument of antiquity extant. A considerable portion of this building has escaped the ravages of time, and affords the antiquary, as well as the architect, an opportunity of examining that division of a theatre on which the actors stood; a part that is wanting in almost all other ruined theatres. The arcades are all composed of brick, the rest of the walls of pebbles, and covered with casings of marble. The whole range of the vomitoria and galleries that encircled the seats is yet standing as high from the ground as the bottom of the second order; the proscenium, which formed the chord of the arch, is almost entire; it is a thick wall, with a large opening in the centre, and three niches; a small door, and a fourth niche on each side; between each of these apertures, or recesses, are marks in the wall, where columns were placed. According to the plan deduced from these ruins, the stage was a parallelogram of 138 feet by 58; on each side was a lofty square building, consisting of a basement and two upper stories, from the highest of which a communicating gallery was carried along the back scenes: the diameter of the semicircular part of the theatre, where the audience sat, was 142 English feet. The streets of the modern town, the courts and houses, are every where interspersed with fragments of antique walls, aqueducts, and mosaic pavements. The ascent to Taormina is very steep and difficult; but the charms of the landscape amply recompense the labour of attaining the height. Every thing belonging to it is drawn in a large sublime style; the mountains tower to the clouds; the castles and ruins rise on weighty masses of perpendicular rock, and seem to defy the attacks of mortal enemies; *Ætna*, with all its snowy and woody sweeps, fills half the horizon; the sea is stretched out upon an immense scale, and occupies the remainder of the prospect. The beach is confined by high cliffs, that are calcareous and consisting generally of a species of red and white marble, which was in high esteem among the ancients. The houses in the vicinity are inhabited by peasants, who occupy them with their children and cattle. These several monuments are undoubtedly coeval with the Romans; that is, posterior to Cæsar, who, having expelled the inhabitants of Tauromenium, placed in it a Roman colony. The origin of this city is lost in the obscurity of ages. It is known that it was considerably augmented, when Dionysius, in the 94th Olympiad, 443 years B.C., having taken and destroyed Naxos, caused it to be deserted by its inhabitants, who settled here. This proud city was at length destroyed by the Venetians, and fortified by the Norman conquerors; and it still exists in a reduced state. When it was taken by the Saracens from the Greek emperor in the 10th century, it was one of the strongest places in the island, and called by them "Al Moezzia," which name it retained for a considerable time; 27 miles S.S.W. of Messina. N. lat. $37^{\circ} 51'$. E. long. $15^{\circ} 23'$.

TAOS LAPIS, the *peacock-stone*, a name given by some of the ancient writers to a very beautiful variegated agate, resembling, in some degree, the great variety of colours in the peacock's tail.

TAOSANLU, in *Geography*, a town of Asiatic Turkey, in Natolia; 20 miles N.W. of Kiutaja.

TAOUKA, one of the Society islands, in the South Pacific ocean. S. lat. $14^{\circ} 30'$. W. long. $145^{\circ} 9'$.

TAP, among *Hunters*. A hare is said to tap, or beat, when she makes a particular noise at rutting-time.

TAP. See TAPPING.

TAP-Root, that sort of root which shoots directly downwards to a great depth. There are many roots of this nature, which are in constant use by the farmer, such as the carrot, parsnip, beet, &c.; and there are many plants of the tree kind which have tap-roots, as the oak, &c.: See TAPPING.

In the vegetable kinds of tap-rooted plants, they all require a deeply broken-down and prepared soil, in order to grow them with any success, and to any considerable sizes. And, as in the tree sorts, they must always rise from the seeds where they are sown; as they cannot be transplanted out with any kind of propriety or advantage. Where the land is not properly prepared to a suitable depth, they are usually short, forked, and of awkward growth; and when raised by transplanting, very small and stunted; but some of them cannot be at all grown in the last method.

TAP-Rooted Turnip, in *Agriculture*, that sort which grows much with this kind of root. It is not a favourable kind of growth for this sort of crop. See TURNIP.

TAPACRI, in *Geography*, a town of Peru; 20 miles N.E. of Cochabamba.

TAPAJOS, a river of Brazil, in the Capitania of Matto Grosso, which runs N. between the Madeira and the Chingu for 300 leagues, flowing into the Amazons, in lat. $2^{\circ} 24' 50''$ and long. 55° , the geographical position of the town of Santarem situated at its mouth. This river rises in the plains of the Parexis, so called from an Indian nation which inhabits them. From these elevated plains descend the two greatest rivers of South America, *viz.* the Paraguay, and the Madeira, the largest river that flows into the Amazons on the south. The Tapajos flows in a contrary direction from these mountains. Its westernmost branch is the river Arinos, which entwines its sources with those of the Cuiaba at a short distance from those of the Paraguay. The largest and westernmost branch of the Tapajos is the Juruena, which rises in lat. $14^{\circ} 20'$, 20 leagues N.N.E. of Villa Bella, and running N. 120 leagues, flows into the Arinos, and with it forms the bed of the Tapajos. The Juruena may be navigated to its upper fall, within two leagues of its own source. From the geographical position of the Tapajos, it is evident that this river facilitates navigation and commerce from the maritime city of Peru to the mines of Matto Grosso and Cuiaba, by means of its large branches, the Juruena and Arinos. The Tapajos is known to be auriferous through a great part of its course.

TAPANANA, a name of the Hindoo regent of the sun. It means the *inflamer*. (See SURYA.) One of the five arrows with which the Hindoo Kama, or cupid, wounds his votaries, is named Tapanana. Its head is formed of a flower of a supposed inflaming quality.

TAPARICA, in *Geography*, an island at the entrance of All Saints' bay, on the coast of Brazil, about 25 miles long, and 5 broad. S. lat. 13° .

TAPAS, the name of a species of devotion, to which great merit and efficacy are ascribed by the Hindoos. It consists of intense contemplation, accompanied by austerities. See JAP.

The performance of the Tapas, or, more correctly written, Tapasya, is strongly recommended in Hindoo books; and numerous instances are there given of benefits conferred on the suppliants by the gods so propitiated. An individual, while in the performance of the penances of Tapasya, is called

called Tapaswi: he is much revered, and his prayers are earnestly solicited by the superstitious as necessarily efficacious. (See RAVENA.) Among his austerities he went through the following series, each of the eleven specific mortifications enduring one hundred years.

1. He stood on one foot, holding the other and both hands up toward heaven, with his eyes fixed on the sun.
2. He stood on one great toe.
3. He took as sustenance nothing but water.
4. He lived similarly on air.
5. He remained in the water.
6. He was buried in the earth, but continued, as in the other inflexions, in incessant adoration.
7. The same in fire.
8. He stood on his head, with his feet upwards.
9. He stood on one hand.
10. He hung by his hands on a tree.
11. He hung on a tree with his head downwards.

Some of the Puranas, or books of divine authority, contain a series of eighteen specific mortifications. One is now lying before us, and we give their denominations, with some explanatory observations.

1. *T'bedesfir*, is an elevation of the head, as the word denotes, during life: in this penance some devotees profess never to sit.
2. *Akas-muni*: this means ethereal contemplation: the aspirant in this case looks constantly on the heavens.
3. *Med'ha-muni*, indicates self-examination: the arms are usually crossed over the breast, and the penitent preserves a thoughtful posture or gait, with downcast looks.
4. *Pherfabahu*, with arms projected horizontally.
5. *Dhamr-pana*, inversion; by suspension on a tree, &c. head downwards, over a fire.
6. *Patala-muni*: this is the reverse of *Akas-muni*, meaning subterrene contemplation; Patala being the name of the lower regions, and Yama the lord thereof. The Patala-muni constantly looks downwards to the earth.
7. *Muni*, preserving continued silence in aid of abstraction. The word means a wife man, a sage, or faint, as well as wisdom and contemplation. We know of no difference between this species of devotion and that called *Jap*, which see.
8. *Chourasi-afin*: the meaning of this compound word is eighty-four sitting positions; but it may have some other more mysterious and less obvious meaning. It would seem to be the reverse of some other penances, the merit of which consist in preserving one posture; whereas this implies an incessant variation to the extent of eighty-four changes.
9. *Kassali*: the *Areka* or betle-nut penance. This consists in standing soles upwards, the head resting on the nut placed on the ground. This is done at stated times; but cannot, one would think, be long continued.
10. *Patali*, the earthly or subterrene penance. This is described to be a partial burying of the body up to the breast, head downwards, and of course under ground, with the feet in the air, as in the last. One can scarcely see at first how this can be done; but probably the earth is placed very loosely about the head, &c. with the body or legs supported against a tree or wall.
11. *Urd'ha-bahu*, with elevated hands, keeping them above the head. This is a common penance, persevered in sometimes till the arms become mere skin and bone, the fore-arms fixed immovably, crossing horizontally, and the finger-nails perhaps perforating the palms. A most eminent *Urdha-bahu* is described, with a portrait, in the fifth volume of the Asiatic Researches, art. ii.
12. *Baitisiri*, sitting posture, never rising or lying.
13. *Nyas-d'hean*, retaining the breath. To this practice great merit is ascribed, and it is persevered in to a very extraordinary extent; till at length no respiration is visible. In this state impostors pretend to beatific visions, and the credulous of course admire the wonders they relate.
14. *Chourangi-afin*, a quadrupedal position, obtained by resting on the elbows and knees, putting the hands backwards over the shoulders, and keeping

hold of the toes. This must be a very awkward and uneasy posture, and not obtainable without much practice.

15. *Brabh-bansa*: this is a stage of austerity much venerated, and easily practicable, at least ostensibly. The devotee professes total indifference to every thing sublunary: he provides or asks for no food or clothing: he wanders or sits naked: if any one bring him food, he eats: his whole time, in short, is occupied in divine contemplation.
16. *Panch-agni*, five fires. The devotee sits on the ground, with a fire to the cardinal points, intense and near in proportion to his ability to bear them. The sun over head is the fifth fire. (See PANCH-AGNI.)
17. *Tirbanghi*, standing on one foot. This *Lakshmi* is related to have done for 100,000 years in the flower of the lotos, during one of her terrestrial incarnations, that she might be reunited to her lord Vishnu. (See PAVAKA.)
18. *Surya-varti*, propitiating Surya, or the sun. This is done in various ways. Sometimes by abstinence merely till he is risen, or until other prescribed ceremonies have been performed. Fixing the eyes constantly on the sun is another mode. See SURYA.

TAPASSANT, among *Hunters*, denotes *lurking*, or *squatting*. Hence also, *to tappy*, is to lie hid, as deer may do.

TAPA-TACSO, in *Geography*, a town of Thibet; 45 miles N.E. of Lassa.

TAPAUACA, a town of South America, in the province of Darien; 40 miles E.S.E. of St. Maria de Darien.

TAPAYAXIN, in *Zoology*, the name of a very remarkable species of lizard, called by Hernandez the *lacertus orbicularis*.

It is not of the long and slender shape of the common lizards, but as broad as it is long, and much resembling the ray-fish in shape, though seldom exceeding four inches in length or breadth. It is a cartilaginous lizard, of a very beautiful variety of colours, always very cold to the touch, and so sluggish a creature, that it often will not move out of its place even on touching it. Its head is exceedingly hard and elate, and has a sort of crown of prickles for its defence; yet it is a perfectly harmless animal, and so far from having the fear of man, and shyness that other beasts have, that it loves to be taken up and played with, and will stand perfectly still, and seem very happy while played with. Hernandez, lib. ix. cap. 16.

TAPE-WORM, a species of worm breeding in the human bowels, and called by authors *tania*, and *lumbricus latus*, or the broad worm. See TENIA.

The Greek and Roman physicians, as well as those of our own time, have described those sorts of worms to which the human bowels are subject. The common long worms, which resemble earth-worms; the ascarides, or small worms; and this tape-worm, which they have also called *vermis cucurbitinus*, or the gourd-worm, from its resembling, in some degree, the seeds of that fruit.

The interpreters of some of the Greek physicians have, however, been guilty of a great error, in confounding the gourd-worms and the ascarides together, though nothing can be more unlike. The ancients seem to have had a very just opinion of this animal in calling it *vermis cucurbitinus*, since it is plain by this, that they understood every joint, as we call them, of this creature, to be a distinct worm; and what we call a single worm, to be a long series of these worms, joined together end to end.

The true history of this animal is, that it is short and broad. What is called a link of the long worm is really a distinct worm; and when one of these multiplies in the bowels, its young adhere to it, and to each other endwise, so as to form a sort of chain, which lengthens as they con-

time to increase, and in fine becomes immoderately long. Hence it is that the breaking, as it is called, of this worm, does not destroy it, and that the voiding large pieces of it is no cure, since it still recovers that length again by new young ones. Every separate link of such a chain, if examined, is found to be entire, lively, and brisk, and not at all injured by the separation.

Dr. Tyfon, in the Phil. Trans. N^o 146, gives a curious account of this worm: it is always single; it lies variously convoluted, being sometimes as long as all the guts, and sometimes it very much exceeds that length. Olaus Borrichius assures us, that a patient of his, in a year's time, voided eight hundred feet in measure of this worm, though in that length he did not meet with the head; in voiding, the patient always observed it to break off.

Dr. Tyfon parallels this case with that of a patient of his, who discharged vast quantities of this worm for several years, but in various pieces, of two, three, four, six, or more yards long, but all put together, would (he says) much exceed the length of that of Borrichius.

The joints in this worm are very numerous. In one of twenty-four feet long, Dr. Tyfon numbered five hundred and seven joints. Above the middle of the edges of each joint, he observed a protuberant orifice. Those orifices he takes for so many mouths; the best microscopes discovering no mouth in that part which usually passes for the head. This worm is common in most kinds of animals, as dogs, oxen, crabs, herrings, pikes, &c.

Some authors have asserted, that it is not one, but many worms linked together, and included in a spodium of the intestines; and that this spodium is not animated, but receives its sense and motion from a sort of vermiculi cucurbitini enclosed in it. This Gabucinus, de Lumb. Com. says, he has plainly discovered; but Dr. Tyfon abundantly evinces the contrary.

Authors who have treated of these worms as a disease, have given a canine appetite, or unnatural appetite to food, as one of the symptoms; but this is wrong, for it has never been found, in reality, that these worms, even where most numerous, have at all increased the natural appetite; and indeed it is very difficult to judge of their being in the body by symptoms, since they occasion none which are not also common in many other diseases. Many people have had them a long course of time, without being sensibly hurt by them; and there has never been known an instance of their occasioning any one's death, or indeed any considerable disorder.

Fern-root has been long known as a remedy against worms. See *Diseases of INFANTS*, and *WORMS*.

However, it was sunk into neglect till a few years ago, when it again came into notice, by being discovered to be the remedy which had become greatly celebrated in Switzerland as a specific in the cure of the *tania* or tape-worm. The secret was purchased by the king of France, after its efficacy had been attested upon trial by some of the principal physicians at Paris.

The following has been published as the mode of its exhibition. After the patient has been prepared by an emollient clyster, and a supper of panada with butter and salt, he is directed to take in bed in the morning a dose of two or three drachms of the powder of male fern-root. The dose to infants is only one drachm. The powder must be washed down with a draught of water, but nothing else must be taken till two hours after, when a bolus of calomel, joined with some of the strongest cathartics, is to be given. If this does not operate, it must be followed by a dose of purging salts. By this method the worm is

commonly expelled in a few hours. If the trial does not succeed, the process must be repeated at due intervals. Lewis's Mat. Med. by Aikin, 1784.

TAPEANDURIAN, in *Geography*, a town on the E. coast of the island of Borneo. N. lat. 1° 24'. E. long. 117° 54'.

TAPEANTAN, a small island in the Sooloo Archipelago. N. lat. 6° 15'. E. long. 122° 9'.

TAPECON, in *Ichthyology*, a name given by some to the fish generally called the *uranoscopus*, or star-gazer.

TAPEINIA, in *Botany*, a little plant of the straits of Magellan, so named by Commerçon, from *ταπεινος*, *humble*, or *low*; Jusl. 59. This is the *Ixia pumila* of Forster, Pl. Magell. 11. t. 2, referred by Vahl to WITSENIA. See that article.

TAPER, TAPERING, is understood of a piece of timber, or the like, when broad at one end, and gradually diminishing to the other; as is the case in pyramids, cones, &c.

To measure taper timber, &c. see *SLIDING-Rule*.

TAPER-Bored is applied to a piece of ordnance, when it is wider at the mouth than towards the breech.

TAPER also denotes a kind of tall wax-candle, placed in a candlestick, and burnt at funeral processions, and in other church solemnities.

Tapers are made of different sizes; in some places, as Italy, &c. they are cylindrical; but in most other countries, as England, France, &c. they are conical or taper; whence possibly the name; unless we rather choose to derive taper in the adjective sense from the substantive *taper*, in the Saxon *tapen* or *tapon*, *cereus*, *wax-candle*.

Both kinds are pierced at bottom, for a pin in the candlestick to enter.

The use of lights in religious ceremonies is of a long standing; the ancients, we know, used flambeaux in their sacrifices, and particularly in the mysteries of Ceres; and they had tapers placed before the statues of their gods.

Some suppose that it was, in imitation of this heathen ceremony, that lights were first introduced into the Christian church; others take it, that the Christians borrowed the practice from the Jews; but recourse need not be had to the one or the other. Doubtless, as in the first ages of Christianity, they had their meetings in obscure subterraneous vaults, there was a necessity for tapers, &c.; and there was even occasion for them after they had the liberty of building churches, those being contrived in such a manner as only to receive very little light, that they might inspire the greater awe and respect by the obscurity.

This original of tapers in churches is the most natural; but it is now a long time since the use of tapers, which necessity first introduced, is become a mere ceremony. St. Paulinus, who lived at the beginning of the fifth century, observes, that the Christians of his days were so fond of tapers, that they even painted them in their churches.

There are two ways of making tapers, the first with the ladle, the second by hand.

In the first, after the wicks (which are usually half cotton, half flax) have been well twisted, and cut of the due length, a dozen of them are hung, at equal distances, around an iron hoop, directly over a large copper basin full of melted wax.

Then taking an iron ladleful of the wax, they pour it gently over the wicks, a little below the tops of them, one after another; so that, the wax running down them, they become soaked and covered with it, and the surplus returns into the basin, under which is a pan of coals to keep it in fusion.

Thus they continue to cast on more and more wax for ten or

or twelve times, till the tapers be brought to the required dimensions. The first cast only soaks the wick, the second begins to cover it, and the rest give it the form and thickness; in order to which, they take care that every cast, after the fourth, be made lower and lower below the wicks to make them taper. The tapers, thus formed, are laid, while yet hot, one against another, in a feather-bed, folded double, to preserve them soft; and afterwards taken out thence, one after another, to be rolled on a long smooth table, with an oblong instrument of box, polished at the bottom, and furnished with a handle above.

The taper thus rolled and polished, a piece of its larger end is cut off, and a conical hole bored in it, with a boxen instrument, into which the pin or point of the candlestick is to be received.

While the broach is yet in the hole, they use to stamp the maker's name and the weight of the taper, with a boxen ruler, on which proper characters are cut. The taper is then hung up to harden, after which it is fit for use.

Making of Tapers by Hand.—The wicks being disposed, as in the former manner, they begin to soften the wax, by working it in hot water, in a narrow, deep, copper vessel. They then take a quantity of this wax out with the hand, and apply it gradually on the wick, which is fastened to a hook in the wall, at the end opposite to the collet; so that they begin to form the taper by the large end, and proceed, still lessening the thickness to the neck or collet.

The rest is performed after the same manner as in tapers made with the ladle, except that they do not lay them in the feather-bed, but roll them on the table as fast as they are formed.

Two things there are to be observed in the two kinds of tapers; the first, that, in the whole process of tapers with the ladle, they use water to moisten the table, and other instruments used therein, that the wax may not flick; and that, in the other, they use oil of olives, or lard, for the same end.

TAPER, Paschal, among the *Romanists*, is a large taper, on which the deacon applies five bits of frankincense, in holes made for the purpose, in form of a cross; and which he lights with new fire in the ceremony of Easter-Saturday.

The Pontifical makes pope Zosimus the author of this usage; but Baronius will have it more ancient; and quotes a hymn of Prudentius to prove it. That pope he supposes to have only established the use of it in parish-churches, which till then had been restrained to greater churches.

F. Papebroch explains the original of the paschal taper more distinctly in his "*Conatus Chronico-Historicus*," &c. It seems that, though the council of Nice regulated the day on which Easter was to be celebrated, the patriarch of Alexandria was enjoined to make a yearly canon of it, and to send it to the pope. As all the other moveable feasts were to be regulated by that of Easter, a catalogue of them was made every year; and this was written on a taper, *cereus*, which was blessed in the church with much solemnity.

This taper, according to the abbot Chastelain, was not a wax-candle made to be burnt; it had no wick, nor was it any thing more than a kind of column of wax, made on purpose to write the list of moveable feasts on; and which would suffice to hold that list for the space of a year.

For, among the ancients, when any thing was to be written to last for ever, they engraved it on marble or steel; when it was to last a long while, they wrote it on Egyptian paper; and when it was only to last a short time, they contented themselves to write it on wax. In process of time,

they came to write the moveable feasts on paper, but they still fastened it to the paschal taper; which practice was observed for a long time at Notre Dame, in Rouen, and throughout the order of Cluny. Such is the original of the benediction of the paschal taper.

TAPERA, in *Ornithology*, a species of swallow. See *HIRUNDO*.

TAPERA dos Bocas, in *Geography*, a town of Brasil, in the government of Para, on the Guanapu; 90 miles S.W. of Para.

TAPERI, a town of Peru; 16 miles N.E. of Cocha.

TAPESTRY, or *TAPISTRY*, a curious kind of manufacture, serving to adorn a chamber, or other apartment, by hanging or lining the walls of it.

Some use tapestry as a general name for all kinds of hanging, whether woven or wrought with the needle; and whether silken, woollen, linen, leathern, or of paper, (in which they are countenanced by the etymology of the word, formed from the French *tapiffer*, to line; of the Latin *tapes*, a cover of a wall or bed, &c.) But, in the common use of our language, the term is now appropriated to a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, &c.

The invention of tapestry seems to have come from the Levant; and what makes this the more probable is, that formerly, the workmen concerned in it were called, at least in France, *Sarazins*, or *Sarazinois*.

Some have supposed that the English and Flemish, who were the first that excelled in it, might bring the art with them from some of the croisades or expeditions against the Saracens. Accordingly they say, that those two nations were the first who set on foot this noble and rich manufacture in Europe, which afterwards became one of the finest ornaments of palaces and churches, &c. At least, if they be not allowed the inventors, they have the honour of being the restorers, of this curious and admirable art, which gives a kind of life to wools and silks, in some respects not inferior to the paintings of the best masters. However, it does not appear at what precise era this manufacture was introduced into Europe; nor is it certain to whom it was owing.

Guicciardin, in his "*Description and History of the Netherlands*," printed at Antwerp in 1582, ascribes the invention of the art of making tapestry hangings to the *Netherlanders*, but he does not assign the time of the invention.

The art of weaving tapestry was brought to England by William Sheldon, esq. about the end of the reign of Henry VIII. See Dugdale's *Warwickshire in Stemmat* Sheldon, p. 384.

In the reign of king James, the manufacture of tapestry was set up at Mortlake, in Surrey. Aubrey, indeed, in his history of that county, dates its institution in the subsequent reign; but Lloyd (*State Worthies*, p. 953.) is not only positive for the former era, but affirms, that at the motion of king James himself, who gave two thousand pounds towards the undertaking, sir Francis Crane erected the house at Mortlake for the execution of the design; and this is confirmed by authentic evidence; for, in Rymers's *Fœdera*, vol. xviii. p. 66, there is an acknowledgment from king Charles in the first year of his reign, *viz.* 1625, that he owes six thousand pounds to sir Francis Crane for tapestry; and he grants to him two thousand pounds yearly, for ten years, towards the maintenance of the said work.

These works at Mortlake, which at first had been conducted after old patterns, were afterwards formed from designs,

designs, both in history and grotesque, furnished by Francis Cleyn, and thus carried to singular perfection.

From the deed above recited, it is plain that the manufacture was then arrived at great perfection. See Mr. Walpole's *Anecdotes of Painting in England*, vol. ii. p. 36.

In the year 1663, a statute was enacted (cap. 15.) for the encouragement of the linen and tapestry manufactures of England, and discouragement of the very great importation of foreign linen and tapestry.

The first establishment of a tapestry manufacture at Paris was under Henry IV., in the year 1606 or 1607, by means of several excellent artists, whom he invited from Flanders.

But this fell with the death of that prince. Under Lewis XIV. the manufacture was retrieved by the care and address of the great M. Colbert, to whom is owing the establishment of the Gobelins, a royal tapestry manufactory, which has produced works of this kind scarcely inferior to the finest English or Flemish tapestry, either with regard to the design, the colours, or the strength.

In this manufactory both wool and silk are used, and sometimes gold and silver. The finest paintings may be copied in this work, and the greatest masters have been employed in draughts for the tapestry weavers.

The weavers of the Gobelins work behind, or on the wrong side of the loom, which stands upright, and the pattern is placed on either side of the workman.

As the tapestry of the Gobelins is made of pieces of a certain breadth only, there are other workmen, called *ren-trayeurs*, or *fine-drawers*, who are employed in sewing or fine-drawing the several parts together, so that no seam is discernible, but the whole appears as one design, like a piece of silk from a loom. These workmen are also useful in mending and cleaning tapestry when damaged or sullied.

The tapestry-men distinguish two kinds of work; *viz.* tapestry of the *high* and the *low warp*, though the difference is rather in the manner of working, than in the work itself, which is, in effect, the same in both, only the looms, and consequently the warps, are differently situated; those of the *low warp* being placed flat, and parallel to the horizon, and those, on the contrary, of the *high warp*, erected perpendicularly.

The French have had three considerable tapestry manufactories besides that of the Gobelins; the first at Aubusson, in Auvergne; the second at Felletin, in the Upper Marche; and the third at Beauvois: they were all equally established for the high and the low warp; but all laid aside the former, excepting that of the Gobelins.

There are admirable low warps in Flanders, generally exceeding those of France; the chief and almost only Flemish manufactories were at Brussels, Antwerp, Oudenard, Lisle, Tournay, Bruges, and Valenciennes.

At Brussels and Antwerp they succeeded both in human figures and animals, and in landscapes: and that both with respect to the designing and the workmanship. At Oudenard their landscapes and animals were good, but their human figures not well executed. Lisle, and the other cities named, came behind Oudenard. The French manufactory of Felletin has done tolerably well in landscapes, Aubusson in figures, and Beauvois in both.

The usual widths of tapestries were from two ells to three ells and a half, Paris measure.

The manufacture of tapestry of each kind (though less fashionable and in use than formerly) is too curious to be here pass over without a short description. We shall give each under its separate article.

Manufacture of Tapestry of the High Warp.—The loom

on which this is wrought is placed perpendicularly: it consists of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across, one at top, and the other at bottom, a foot distance from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove, from one end to the other, capable of containing a long round piece of wood, fastened in it with hooks. Its use is to tie the ends of the warp to. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as woven, is wound on the lower.

Withinside the planks, which are seven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end, serving to sustain the coat-stave: the pieces of iron have also holes pierced in them, by putting a pin in which, the stave is drawn nearer, or set farther off; and thus the coats or threads are stretched and loosened at pleasure. The coat-stave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats, or threads, which make the threads of the warp cross each other. It has much the same effect here as the spring-stave and treddles have in the common looms. The coats are little threads fastened to each thread of the warp, with a kind of sliding-knot, which forms a sort of mesh or ring. They serve to keep the warp open, for the passages of broaches wound with silks, woollens, or other matters used in the piece of tapestry.

Lastly, there is a number of little sticks, of different lengths, but all about an inch diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing them across: and that the threads thus crossed may retain their proper situation, a packthread is run among the threads above the stick.

The loom thus formed, and mounted with its warp, the first thing the workman does, is to draw, on the threads of this warp, the principal lines and strokes of the design to be represented on the piece of tapestry; which is done by applying cartoons made from the painting he intends to copy, to the side that is to be the wrong side of the piece; and then with a black-lead pencil following and tracing out the contours of them on the thread of the right side; so that the strokes appear equally both before and behind. As to the original design the work is to be finished by, it is hung up behind the workman, and wound on a long staff, from which a piece is unrolled, from time to time, as the workman proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk, or wool of the woof within the threads of the warp. These are a broach, a reed, and an iron needle.

The broach is of hard wood, seven or eight inches long, and two-thirds of an inch thick, ending in a point, with a little handle. It serves as a shuttle, the silks, woollens, gold, or silver, to be used in the work, being wound on it. The reed, or comb, is also of wood, eight or nine inches long, and an inch thick at the back; whence it usually grows less and less, to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work.

Lastly, the needle is in form of a common needle, only bigger and longer. Its use is to press close the wool and silks, when there is any line or colour that does not fit well.

All things being prepared for the work, and the work-

TAPESTRY.

man ready to begin, he places himself on the wrong side of the piece, with his back towards the design; so that he works, as it were, blindfold, seeing nothing of what he does; and being obliged to quit his post, and go to the other side of the loom, whenever he would view and examine the piece, to correct it with his pressing-needle.

To put any filk, &c. in the warp, he first turns and looks at his design; then taking a broach full of the proper colour, he places it among the threads of the warp, which he brings across each other with his fingers, by means of the coats or threads fastened to the staff: this he repeats every time he is to change his colour.

The filk, or wool, being placed, he beats it with his reed, or comb; and when he has thus wrought in several rows over each other, he goes to see the effect they have, in order to reform the contours with his needle, if there be occasion.

As the work advances, they roll it up on the lower beam, and unroll as much warp, from the upper beam, as suffices them to continue the piece: the like they do of the design behind them. When the pieces are wide, several workmen may be employed at once.

We have but two things to add: the first, that this high-warp tapestry goes on much more slowly than the low-warp, and takes almost double the time and trouble. The second, that all the difference the eye can observe between the two kinds consists in this, that in the low warp there is a red fillet, about one-twelfth of an inch broad, running on each side from top to bottom; which is wanting in the high warp.

Manufacture of Tapestry of the Low Warp.—The loom, or frame, on which the low warp is wrought, is much like that of the weaver's: the principal parts of it are two strong pieces of wood forming the sides of the loom, and bearing a beam, or roller, at each end: they are sustained at bottom with other strong pieces of wood, in manner of trestles; and to keep them the firmer, they are likewise fastened to the floor with a kind of buttresses, which prevent any shaking, though there are sometimes four or five workmen leaning on the fore-beam at once.

The rollers have each their trunnions, by which they are sustained: they are turned by large iron pins three feet long. Along each beam runs a groove, in which is placed a *wich*, a piece of wood of about two inches diameter, and almost of the length of the roller: this piece fills the groove entirely, and is fastened in it, from space to space, by wooden pins. To the two wiches are fastened the two extremities of the warp, which is wound on the farther roller; and the work, as it advances, on the nearer.

Across the two sides, almost in the middle of the loom, passes a wooden bar, which sustains little pieces of wood, not unlike the beam of a balance: to these pieces are fastened strings, which bear certain spring-staves, with which the workman, by means of two treddles, under the loom on which he sets his feet, gives a motion to the coats, and makes the threads of the warp rise and fall alternately. Each loom has more or fewer of these spring-staves, and each staff more or fewer coats, as the tapestry consists of more or fewer threads.

The design or painting, the tapestry-man is to follow, is placed underneath the warp; where it is sustained from space to space with strings, by means of which the design is brought nearer the warp.

The loom being mounted, there are two instruments used in working of it: *viz.* the reed, and the flute. The flute does the office of the weaver's shuttle; it is made of an hard polished wood, three or four lines thick at the ends, and

somewhat more in the middle, and three or four inches long. On it are wound the filks, or other matters, to be used as the woof of the tapestry. The comb or reed is of wood or ivory; it has usually teeth on both sides; it is about an inch thick in the middle, but diminishes each way to the extremity of the teeth: it serves to beat the threads of the woof close to each other, as fast as the workman has passed and placed them with his flute among the threads of the warp.

The workman is seated on a bench before the loom, with his breast against the beam, only a cushion or pillow between them; and, in this posture, separating, with his fingers, the threads of the warp, that he may see the design underneath, and taking a flute, mounted with a proper colour, he passes it among the threads, after having raised or lowered them, by means of the treddles moving the spring-staves and coats.

Lastly, To press and close the threads of the silk or yarn, &c. thus placed, he strikes each course (*i. e.* what the flute leaves in its passing and coming back again) with the reed.

What is very remarkable in the manufacture of the low warp, is, that it is all wrought on the wrong side; so that the workman cannot see the right side of his tapestry, till the piece be finished and taken out of the loom.

M. Le Blon, in endeavouring to fix the true harmony of colouring in painting, found that all visible objects may be represented by the three primitive colours, red, yellow, and blue; because out of these, all others, even black itself, may be compounded.

From the principle of producing any visible object with a small number of colours, and from observing the compounded colours which were reflected from two pieces of silk of different colours, placed near to one another, he arrived at the skill of producing in the loom all that the art of painting requires. In weaving, indeed, he hath been obliged to make use of white and black threads, besides red, yellow, and blue; and though he found that he was able to imitate any picture with these five colours, yet for cheapness and expedition, and to add a brightness where it was required, he found it more convenient to make use of several intermediate degrees of colours.

In his new way of weaving tapestry in the loom with a draw-boy, it may be performed almost as expeditiously as fine brocades; for when the loom is once set and mounted, any common draught-weaver, unacquainted with drawing or painting, and indeed hardly knowing what figure he is about, may exactly produce what the painter hath represented in the original pattern: and thus a piece of tapestry may be woven in a month or two, which, in the common way of working, would take up several years; and what in the common way costs a thousand pounds, may, by this means, be afforded finer and better for a hundred.

The main secret of this consists in drawing the patterns, from which any common draught-weaver can mount the loom; and when that is done, the piece may be made of any size, by only widening the reeds and the warp; and a reverse may be made with the same ease; which is done by the boy's pulling the lashes up again in the same order in which he pulled them down before: by which contrivance the tapestry may be suited to any room, whether the light comes in on the right, or on the left. The patterns are painted upon paper, on which are printed squares from copper-plates, and these subdivided by as many lines as answer to the threads of the warp, which run lengthwise of the piece; then they try how many threads of the shoot answer in breadth to every subdivision of the squares. Every thread

of the warp goes through a small brass ring called a *male*, or through a loop in the leish, and hath a small long weight or lingoe hung below, to counterbalance the packthreads, which going from the top of the rings or loops, are passed over the pullies in the table directly over the loom, and are continued nearly in an horizontal position on one side of the loom to a convenient distance; where they are all spread on a cross piece fastened to two staples: these are called the *tail of the mounture*; and from each of these packthreads, just by the side of the loom, are fastened other packthreads, called *simples*, which descend to the ground; so that by pulling these simple cords, you raise any of the threads of the warp at pleasure: wherefore they fasten a loop or potlart to as many of these simple cords as there are threads of the warp to be pulled up at every shoot, or every throw of the shuttle; by which means the shoot shews itself on the right side, where the warp is pulled up: and in ordering this, they are guided by the pattern, on which they count the distances of the subdivisions, which contain the same colours in the same line, and can be shot at once: then they fasten potlarts to the several simple cords that draw up the rings, through which those threads of the warp run, which are to lie behind this colour; they tie all these loops together, and fasten a piece of worsted or silk to the knot, of the same colour that the workman is to throw; and the boy, when he pulls each loop, names the colour, that the weaver may take the proper shuttle, and so on for every colour to be thrown. Phil. Trans. abr. vol. vi. p. 469, &c.

In connection with this subject, we are naturally led to give a brief account of the manufacture of carpets. This is said to have been introduced into France from Persia, in the reign of Henry IV., where it has been distinguished by extraordinary encouragement. The most considerable manufactory of this kind was that of Chaillot, or the royal manufactory of La Savoniere, or the Soap-house, about a league from Paris. This manufacture was altogether of wool, and worked in the manner of velvet. All sorts of figures of animals may be imitated in this work, but fruits and flowers answer best; and it is most successfully applied to the manufacture of carpets and all sorts of screens.

The carpets are, in some respect, wrought by the upright way of tapestry. The two rollers are placed the same way: the warp is braced from the top downward; the chain, with its loops, keeps all the threads of the warp equally perpendicular; the stick, which facilitates their crossing, runs through them in the same manner, and separates the foremost threads from the rest; the lizier-pole holds all the strings, which serve to draw the fore-threads in their turns, and then the opposite threads, in order to insert the spindles of wool. But the method of working in this manufactory differs from the upright way of tapestry in the following particulars.

The warp is divided, both before and behind, into parcels of ten threads, nine white and one blue; which is regularly continued through the whole width of the piece. The weaver works on the fore-side, and consequently sees what he does. The design or pattern is traced in its proper colours on cartons, tied about the workman, who looks at it every moment, because every stitch is marked upon it, as it ought to be in his work. By this means he always knows what colours and shades he is to use, and how many stitches of the same colour. In this he is assisted by squares, into which the whole design is divided; each square is subdivided into ten vertical lines, corresponding with each parcel of ten threads of the warp; and besides, each square is ruled with ten horizontal lines, crossing the vertical lines at right angles. The workman having placed his spindles of thread near him.

begins to work on the first horizontal line of one of the squares. These lines marked on the carton are not traced on the warp, for this would be endless; because an iron-wire, which is longer than the width of a parcel of ten threads, supplies the place of a cross line. This wire is managed by a crook at one end, at the workman's right hand; towards the other end it is flatted into a sort of knife, with a back and edge, and grows wider to the point. The workman fixes his iron wire, or rod, horizontally on the warp, by twisting some turns of a suitable thread of the woof round it, which he passes forward and backward, behind a fore-thread of the warp, and then behind the opposite thread, drawing them in their turn by their leishes. Afterwards, if it be necessary, he brings his woof-thread round the wire, in order to begin again to thrust it into the warp. He continues in this manner to cover the iron rod or wire, and to fill up a line to the tenth thread of the warp, which is the blue one. He is at liberty either to stop here, or go on with the same cross line in the next division. According as he passes the thread of the woof round the iron wire, and into the warp, the threads of which he causes to cross one another at every instant; when he comes to the end of the line, he takes care to strike in, or close again all the stitches with an iron reed, whose teeth freely enter between the empty threads of the warp, and which is heavy enough to strike in the woof he has used. This row of stitches is again closed and levelled, by a dweet of blue thread doubled, which the workman puts into the warp, sliding his hand over the whole length of line he has wrought. He crosses the same threads of the warp, and then stretches through them another single blue thread. He beats in these two threads, one after another, with his reed; these dweets of cross thread, which are a support to each line, will be hid by the pile on the fore-side, and they indeed diminish the beauty of the wrong side; but this is of no consequence. This done, the workman draws the iron rod or knife out of the loops of the woof that covered it; and as it is wider towards its end, these loops resist its passage; but being edged at its fore part, it cuts them through. Then the workman with his left hand lays a strong pair of shears along the finished line, cuts off the loose hairs, and thus forms a row of tufts perfectly even, which, together with those before and after it, form the shag. One line of this sort comprehending the row of stitches and woollen pile, with the two blue threads which support them, somewhat surpasses in thickness the space between the first and second cross line of a square. By this means the workman always sees what he is doing. He follows, stitch for stitch and colour for colour, the plan of his pattern which he is at, and paints magnificently, without having the least notion of painting or drawing.

The manufacture of carpets, after the manner of Chaillot, was introduced into London in the year 1750, by two workmen who left the manufactory in disgust, and came here to procure employment. They were encouraged and furnished with materials by Mr. Moore, to whose assiduity and zeal the establishment of this sort of manufactory has been principally owing. However, these men afterwards connected themselves with a Mr. Peter Parisot, who, under the patronage, and by means of the pecuniary assistance of his royal highness the duke of Cumberland, pursued the manufacture of a carpet already begun at Paddington. This undertaking was soon removed to Fulham, and, under the munificence of the duke, promised to be durable and advantageous. In 1752, Parisot, the undertaker, proposed a plan of subscription, the nature of which it is now needless to recite; as the whole scheme, as far as he was concerned in it, soon came to nothing. But Mr. Moore, being provided

vided with the necessary materials, and engaging proper workmen, and risking a very considerable expence, succeeded in establishing this important and useful manufacture, inasmuch that, in 1757, he obtained a premium from the Society of Arts, &c. for the best carpet in imitation of the Turkey carpets; and by his ingenuity and perseverance in bringing this manufacture to perfection, it is now arrived at a very high degree of reputation.

Mr. Whitby and Mr. Paffavant were also honoured with premiums for carpets of their manufacture by the Society of Arts in 1757 and 1758. We have also manufactories for carpets that are much esteemed at Axminster and Wilton; not to mention those of Kidderminster and other places.

TAPETI, in *Zoology*, the name of an animal common in the West Indies, and called by some *cuniculus Americanus*, the American rabbit. In the Linnæan system, this animal is a species of hare, or *lepus Brasiliensis*. (See **LEPUS**.) It has large ears like the common hare; a white ring round the neck, though some have not this ring; the face of a reddish colour; the chin white, the eyes black; colour of the body like that of the common hare, but darker; the body whitish, without a tail. These animals inhabit Brasil, live in woods, do not burrow, are very prolific, and afford good meat. The tapeti is found also in Mexico, where it is called *cilli*. Pennant.

TAPHICESIUS LAPIS, a name given by Pliny and the ancients to a species of ætites, or eagle-stone, found in a place of that name near Leucadia.

TAPHNEUS, a word used by some writers to express any thing when depurated or purified to the greatest degree, as the salts, by repeated solutions and crystallizations, and the like. Paracelsus uses it for a species of earth, the things produced from which, he says, never alter their nature by calcination or reverberation, or the like operations.

TAPHNIS, in *Ancient Geography*, a town of Egypt, mentioned by the prophet Jeremiah, to which he and the Israelites that were with him retired.

TAPHRA, a town situated in the isthmus of the Tauric Chersonesus, mentioned by Pliny and Strabo.

TAPHROS, a name which was given to the strait that separates the island of Sardinia from that of Corsica.

TAPHRURA, or **TAPHRA**, a town of Africa Propria, upon the gulf of Numidia.

TAPHUA, a town of Palestine, in the tribe of Juda. — Also, a town of Palestine, which belonged to the tribe of Ephraim, and was situated upon the frontier of that of Manasseh.

TAPIA, in *Botany*, an American name, adopted by Plumier from Pifo. See **CRATEVA**.

TAPIA, in *Geography*, a town of South America, in the kingdom of New Granada, and province of St. Martha.

TAPIAN POINT, a cape on the W. coast of Mindanao. N. lat. 7°. E. long. 124° 30'.

TAPIAU, a town of Prussia, in Samland, on the Pregel; 20 miles E.S.E. of Königsberg. N. lat. 54° 36'. E. long. 21° 13'.

TAPICURU, a river of Brasil, which runs into the sea, S. lat. 12° 20'.

TA-PI-HOTUN, a town of Corea; 690 miles E. of Peking. N. lat. 40° 20'. E. long. 125° 22'.

TAPINOSIS, *ταπεινωση*, in *Rhetoric*, the same with *diminution*; which see.

TAPION, LE, in *Geography*, a town on the W. coast of Hispaniola; 10 miles E. of St. Marc.

TAPIR, or **TAPIJERETE** of Marcgrave, in *Zoology*, the name of an animal found in some parts of America; and

called by the Portuguese *anta*, by others *danta*, by Dampier *vache montagnarde*, and by others *elan*, and *fus aquaticus terrefstris*. Gmelin makes it a distinct genus; and his generic characters, amended by Dr. Shaw, are as follow; *front teeth* in both jaws ten; *canine teeth* in both jaws single, incurvated; *grinders* in both jaws five on each side, very broad; *feet* with three hoofs, and a false hoof on the fore-feet. This animal (*Tapir Americanus*) is of the size of a young calf, or heifer, and in shape somewhat approaching to the figure of the hog, and the back arched; its head is thicker than a hog's, and ends in a sharp ridge at top; and the male has a snout, or sort of proboscis, hanging over the opening of the mouth, in which he has a very strong muscle, serving to retract it at pleasure; the nose of the female is destitute of the proboscis, (this circumstance is doubted by Sonnini,) and the jaws are of equal length; its eyes are small, and very like those of the hog; its ears roundish, bordered with white; and these he can draw forward at pleasure; its legs are thick, and not longer than those of our hogs; its fore-hoofs are divided into three portions; and a sort of false hoof behind; but its hind-hoofs into three; its tail is very small; the skin is hard and solid; and the hair short, and of a pale brown, and when young, variegated with white spots; and along the neck is a bristly mane, an inch and a half high. It lives in thick woods, on the eastern side of South America, from the isthmus of Darien to the river of the Amazons; and sleeps all day, but at night, or early in the morning, goes out for its prey: it feeds on vegetables, and is particularly fond of the stalks of the sugar-cane; it often takes the water, and swims excellently: the natives, in places where it is common, eat its flesh, which is said to be good: the Indians shoot it with poisoned arrows, and cut the skin into bucklers. This animal is falacious, slow-footed, and sluggish, and makes a kind of hissing noise; but perfectly harmless: the young are easily tamed, and may be rendered domestic, which is said to be the case in some parts of Guiana. When attacked by dogs, it makes a vigorous resistance. The tapir produces but one young at a birth, of which it is very careful, leading it at an early age to the sea, and instructing it to swim. Ray and Pennant.

TAPIRIA, in *Botany*, Juss. 372, slightly altered from the still more barbarous *Tapirira*, Aubl. Guian. 470. t. 188, which is itself an alteration of the Caribbean name *Tapiriri*, by which this tree is known in Guiana. See **JONQUETIA**.

TAPIR-TALA, in *Geography*, a town of Chinese Tartary. N. lat. 43° 15'. E. long. 120° 39'.

TAPIS. See **TUNICA**.

TAPL, in *Geography*. See **TOPEL**.

TAPLAKEN, a town of Prussia, in Samland, on the Pregel; 24 miles E. of Königsberg.

TAPLEYS, a town of North Carolina; 12 miles N.E. of Hillsborough.

TAPLINGS, in the *English Salt-Works*, the name given to certain bars of iron which support the bottom of the pan in which the brine is boiled.

These pans are very large, and cover a wide furnace; but as their width would make them apt to bend in the middle, which would spoil the working of the salt, there is a sort of wall of brick carried along the middle of the furnace, and on the top of this are placed these taplings: they are about eight inches high, and from four to six in thickness, being smallest at the top. These are placed at about three feet distance one from another, and the wall which supports them, and which is called the *mid-feather*, is broad at the base, and so narrow at the top, as barely to give room for the bases of the taplings.

TAPOAMANAO, in *Geography*. See *Sir Charles*
Smith's Journal.

TAPOANA, a river of Brasil, which runs into the sea,
 S. lat. $21^{\circ} 10'$.

TAPOCOROI, a river of Brasil, which runs into the sea,
 S. lat. 27° .

TAPOGOMEA, in *Botany*, from the Caribbean name
 of one of the species, *Tapogomo*; Aubl. Guian. 157. Juss.
 208. See *CALICOCCA*.

TAPOOKAS, in *Geography*, a town of the state of
 Georgia, on the Yazoo. N. lat. $35^{\circ} 57'$. W. long.
 $89^{\circ} 51'$.

TAPPOOL, a small island in the Sooloo Archipelago.
 N. lat. $5^{\circ} 37'$. E. long. $120^{\circ} 52'$.

TAPPOOR, a town of Hindoostan, in the Mysore;
 15 miles S.S.W. of Darampoory.—Also, a river of Hin-
 doostan, which runs into the Cauvery, 4 miles N. of Cave-
 ripatam.

TAPOSIRIS, in *Ancient Geography*, a town of Egypt,
 at some distance from the sea, between Cynossena and Pin-
 thyna.—Also, another town, called *Parva Taposiris*, on a
 tongue of land between the sea and the canal which passed
 from Canopus to Alexandria.

TAPPA, in *Geography*, one of the small Molucca islands;
 separated by a narrow channel from Latalatta: on it is a
 pool of fresh water; a little to the north of the line.
 E. long. $127^{\circ} 5'$.

TAPPAHANOCK, a town of the United States
 of America, in Virginia, on a small river, which runs into
 the Rappahanoek; 43 miles N.E. of Richmond. N. lat.
 $37^{\circ} 58'$. W. long. $76^{\circ} 55'$.

TAPPALANG, a town on the west coast of the island
 of Celebes. S. lat. $2^{\circ} 25'$. E. long. $119^{\circ} 5'$.

TAPPAN. See *ORANGE-TOWN*.

TAPPANOOLY, a sea-port town of the island of Su-
 matra, situated on the west coast, in the country of Batta,
 on a small island called Punchongeacheeie. The bay is
 very deep, capable of containing the united navies of Eu-
 rope, and consisting of a number of harbours within one
 another. The bay stretches into the heart of the Batta do-
 minions, and its borders are inhabited by that people, who
 barter here the produce of their country for such articles as
 they want. The English East India company have a fac-
 tory here. N. lat. $1^{\circ} 40'$. E. long. $98^{\circ} 12'$.

TAPPI, or **TAPI**, called by the Moors *Chedder*, a river
 of Hindoostan, which, as Thevenot says, has its source
 ten miles from the little town of Bempore, in the kingdom
 and mountains of Deccan, and runs into the sea about $2\frac{1}{2}$
 leagues below Surat. The Banians and Gentoos esteem this
 a very holy river.

TAPPING, the act of piercing a hole in a vessel, and
 applying a tube, or cannula, in the aperture, for the com-
 modious drawing off the liquors contained therein.

TAPPING, in *Agriculture*, is the making an incision in the
 bark of a tree, and letting out the juice.

To tap a tree at the root, is to open it round about the
 root.

Ratray, the learned Scot, affirms, that he has found by
 experiment, that the liquor, which may be drawn from the
 birch-tree in the spring-time, is equal to the whole weight of
 the tree, branches, roots, and all together.

In the tapping of trees, the juice, taken in from the
 earth, ascends from the root; and, after it is concocted and
 assimilated in the branches, &c. it descends, like a liquor in
 an alembic, to the orifice or incision where it issues out.

One of the most effectual ways of tapping, so as to obtain
 the greatest quantity of sap in the shortest time, is not only

to pierce the bark; or to cut the body of the tree almost to
 the pith, with a chisel (as some have directed), but to bore
 it quite through all the circles, on both sides of the pith,
 leaving only the outermost and the bark on the north-east
 side unpierced.

This hole is to be bored sloping upwards, as large as the
 largest auger will make; and that also through and under a
 large arm near the ground. So will it not need any stone to
 keep open the orifice, nor tap to direct the sap into the
 receiver.

By this method the tree will, in a short time, afford liquor
 enough for brewing; and with some of this sweet sap, one
 bushel of malt will make as good ale as four bushels of malt
 with ordinary water. The large maple, which we call the
 sycamore, is said to yield the best brewing sap, its juice
 being very sweet and wholesome. See *BETULA*.

To preserve the Sap for Brewing.—Infolate it by a constant
 exposure to the sun in proper vessels, till the rest be gathered
 and ready, otherwise it will contract an acidity: when there
 is enough, put into it as much very thin cut and hard-toasted
 rye-bread, as will serve to ferment it; and when it works,
 take out the bread, and bottle up the liquor. A few cloves
 in each vessel that receives the sap, as it oozes from the tree,
 will also, certainly, preserve it a twelvemonth. See *Dr.*
Tonge's Obs. in the *Philosophical Transactions*, N^o 43, 44-
 46. 68. or *Abr.* vol. ii. p. 673, &c.

TAPPING of Oaklings and other Trees, the practice of cutting
 off the tap-roots of young oaks and other trees or plants of
 that kind.

It has been noticed by Mr. Nicol, in his work on planting,
 that those who are in favour of this method, rather than that
 of sowing the seeds of these sorts of trees, suppose that
 tapping the downward roots of the young plants while they
 are in the nursery plantation, has the power and capability
 of making their roots ever afterward have a horizontal ten-
 dency in the earth or soil; that in consequence of it they are
 not liable to injury by insinuating themselves downwards into
 bad soil; and that by a plentiful planting of nursing plants,
 to draw them upright, the necessity of heading them down
 is prevented. But that these are correct and solid arguments,
 he thinks, it is much to be questioned. No doubt, he sup-
 poses, exists that tapping is of infinite advantage to all tap-
 rooted plants of the tree kind, previous to their removal,
 since it causes them to put forth fibres on the upper part of
 the root, which they otherwise would not have done; fitting
 them thereby for being transplanted into shallow soils, and
 for seeking pasturage for the sustenance of the plants. But
 that the roots will, ever afterwards, have a horizontal ten-
 dency, may, it is believed, be fairly denied. Every plant,
 unless constrained, it is maintained, will follow its own nat-
 ural inclinations and habits of growth. Nor can all the art
 of man prevent a downward tendency in the roots of these
 sorts of tree-plants, and at the same time allow them depth
 of soil. See *TAP-ROOT*.

TAPPING of Springs, the practice of boring through the
 surface covering materials of land with the auger, and
 letting off the hurtful water which is pent up, confined,
 and contained in the clayey bed or stratum below. See
SPRING-Drain.

TAPPING, a term applied to an operation which is some-
 times performed on sheep for removing a disease of the local
 dropsical kind in the head. It is executed either by means
 of a very large pin, or a trocar made for the purpose. See
STURDY.

TAPPING, in *Mechanics*, a term applied to the making and
 rectifying of female screws by means of a tap, *i. e.* a screw
 prepared and reserved for this purpose. The process, which
 consists

confists of various manipulations, is minutely described in Nicholson's Journal, vol. i. p. 160—163. See SCREW.

TAPPING, in *Surgery*. See PARACENTESIS.

TAPPOOS, in *Geography*, a town on the W. coast of Sumatra; 25 miles N. of Tappanooly.

TAPROBANA, or TAPROBANE, in *Ancient Geography*, a name anciently given to the island of *Ceylon*; which see.

TAPSAGUN, a town in the interior of Africa, and one of those which were subjugated by Cornelius Balbus.

TAPSAS, a river of Africa, which ran near the town of Rusicada.

TAPSON, in *Geography*, a town of Thibet; 50 miles E. of Tchontori.

TAPSUS, or THAPSUS, in *Ancient Geography*, a peninsula on the eastern coast of Sicily, between Hybla parva and Syracuse.—Also, a promontory of Africa, 12 leagues E. of the promontory Tritum. This formed the eastern extremity of the Sinus Numidicus.

TAPTEE, in *Geography*, a river of Hindoostan, formed by the union of several smaller rivers in the Candish country, which runs into the gulf of Cambay, about 12 miles below Surat. See TAPPI.

TAP-TOO. See TAT-TOO.

TAPUI-TAPERA, in *Geography*, a town of Brasil, on the coast; 15 miles N.W. of St. Luis de Marannon.

TAPURA, in *Botany*, an unexplained name of Aublet's. See ROHRIA.

TAPURA, in *Ancient Geography*, a town of Asia, in the mountains of Lesser Armenia.

TAPURI, or TAPYRI, a people of Asia, in Media.

TAPURI Montes, mountains of Scythia, on this side of mount Imaus. Ptolemy.

TAPUYAS, in *Geography*, a river of Brasil, which runs into the river of the Amazons; the banks of which are inhabited by Indians, independent of the Portuguese.

TAQUARI, a river of Brasil, having the largest of its many mouths in the Paraguay, in lat. 19° 15', and long. 54°.

TAR. See PAMLICO.

TAR, or *Tarr*, a thick dark-brown or black resinous adhesive juice, issuing from the wood and bark of old pines or firs, either naturally, or by burning. See PINUS.

Some modern writers inform us, that tar flows from the trunks of pines and firs, when they are very old, through incisions made in the bark near the root; that pitch is only tar inspissated; and both are the oil of the tree grown thick and black with age and the sun. The trees, like old men, being unable to perspire, and the secretory ducts obstructed, they are, as one may say, choked and stuffed with their own juice. But the method used by our colonies in America of making tar and pitch, is, in effect, the same with that of the ancient Macedonians; as appears from the account given in the Philosophical Transactions. And the relation of Leo Africanus, who describes, as an eye-witness, making of tar on mount Atlas, agrees in substance with the methods used by the Macedonians of old, and the people of New England of this day. The greater part of the tar imported into Britain is brought from the Baltic, and is still prepared in nearly the same method which is described by Dioscorides as having been practised by the ancients. The branches of the trees are cut into billets, and piled up in large stacks, which are covered with turf. Fire is then applied to the wood, and it is suffered to burn with a slow smothered flame, during which process the tar is formed by the decomposition of the resinous juice, which flows to the bottom, and runs out through a small channel cut for the purpose. The stacks are generally built on the slope of a

hill, so that the tar is easily collected, and put into barrels; in which state it is brought into this country. The process now described is termed "distillatio per descensum." See PINE.

A more expeditious and economical method of obtaining tar is practised in France and Switzerland. The wood is heated in large brick ovens, constructed for the purpose, and thus it is charred more equally, and the tar is of a more uniform and better quality. In the Vallais the pines are felled in the preceding year, that the wood may be sufficiently dry, and when the outer bark and twigs are stripped off, the remainder of the tree is cut into billets of tolerably equal size. The oven is constructed of stone or brick, of the shape of an egg placed on its small end: the floor is made either of a flat stone, scooped out into a hollow, or of several stones accurately joined together. On one side of it, about five inches above the lowest part, is a hole, in which a gun-barrel is thrust, and this serves to convey off the liquid tar that is collected. A large iron grate is laid at the bottom of the oven. The largest of these ovens are about ten feet high, and five or six feet in the largest diameter. In charging the oven, bundles of billets are thrown in and spread as evenly as possible, the interstices being filled with chips, till the charge nearly reaches the top. The whole is then covered with a layer of chips, and the top of the furnace is closed with flat stones heaped upon one another, gradually lessening the opening, and forming a kind of vaulted chimney, the mouth of which is four or five inches across. The dry chips at the top of the furnace are then set on fire, and the heat spreads downwards, till the whole charge is sufficiently kindled. The chimney is then entirely closed with a large stone, and wet earth is heaped on the stones at top, and thrown on wherever the smoke is observed to burst out too strongly. The melting then begins, and the tar falls to the bottom, fills the hollow of the floor (which detains any bits of wood and other impurities), and runs off through the gun-barrel into casks placed for receiving it. The fire must be occasionally refreshed by letting in a small draught of air through small holes left for the purpose in the sides of the kiln. When the process is finished, the wood, completely charred, is taken out, and the oven, after having been cleared out, is again filled. The red wood and knots, being the richest in resin, are found to yield about one-fourth of their weight of tar; but the general average product is about 10 or 12 per cent. of the weight of the whole charge. After each process, a quantity of "lamp-black" is collected beneath the stones that form the vault of the temporary chimney.

According to Theophrastus, not only the turpentine-trees, the pines, and the firs yield resin or tar, but also the cedars and palm-trees; and the words *pix* and *resin* are taken by Pliny in so large a sense, as to include the weepings of the lentiscus and cypress, and the balsms of Arabia and Judæa; all which perhaps are near of kin, and in their most useful qualities concur with common tar, especially the Norwegian, which is the most liquid and best for medicinal uses. Those trees that grow on mountains, exposed to the sun or north wind, are reckoned to produce the best and purest tar; and the Idæan pines were distinguished from those growing on the plain as yielding a thinner, sweeter, and better scented tar. Every part of the tree, which is at all resinous, is fit for yielding tar; but the red wood and the hard roots yield the best in quality as well as the greatest in quantity.

Every kind of wood will produce the *pyroligneous* acid (which see), and tar by the destructive distillation. Peat also will yield it in abundance.

There is also a kind of tar, the project of making which was suggested by Becher, the celebrated chemist, in the time of king Charles II., which has for several years been prepared from coal in the bishopric of Liege, and in other parts of Germany: we also make considerable quantities in England, especially near Broseley, in Shropshire, and at Bristol. In the bishopric of Liege the coal is distilled in a kind of still, composed of two large cast-iron pots. In England the coal is put into ovens, which are heated by fires lighted under their bottom, and the liquid matter is forced through an iron pipe inserted into the top of the oven, and which communicates with proper condensing vessels. Watson's Chem. Ess. vol. ii. p. 346, &c.

The earl of Dundonald, in Scotland, has lately invented the art of extracting tar and pitch from pit-coal, by a new process of distillation. See Address and Proposals by Sir John Dalrymple, 1784.

A substance resembling tar, called "brai-gras," and much used by the French for careening ships, is made in the following manner. The oven, described in the preceding part of this article, is charged with alternate layers of chips of green wood, and billets of dry, and all the refuse matter of turpentine, &c. Over the whole is laid a stratum of "brai-hec," or rosin, and the gun-barrel pipe is stopped up, and not tapped till the whole of the wood is reduced to charcoal. The vault of the oven is also covered more carefully after the charge is sufficiently kindled, and the whole process is carried on more slowly, and the heat of the fire melts the rosin at the top, which mixes with the resinous sap, and the whole concretes into a dark resinous liquid at the bottom. When it is sufficiently cooled, it is drawn off and barrelled. This "brai-gras" is of an intermediate consistence between tar and rosin. Aikin's Dict.

Tar is properly an empyreumatic oil of turpentine, and has been much used as a medicine both internally and externally.

Tar in substance, mixed with honey, has been found an excellent medicine for coughs.

The ancients esteemed tar good against poisons, ulcers, the bites of venomous creatures; also for phthical, scrofulous, paralytic, and asthmatic persons. But the method of rendering it an inoffensive medicine, and agreeable to the stomach, by extracting its virtues in cold water, was unknown to them. Siris, sect. 9. 16, 17. 21. 28. See TAR-water, infra.

Tar is sometimes given in substance, mixed with so much powdered liquorice, or other such powdery matter, as is sufficient to render it of a fit consistence to be formed into pills. An ointment of tar has been directed in the pharmacopeias, which has been chiefly employed in cutaneous disorders. See UNGUENTUM à Pice.

Dr. Cullen mentions an empirical practice, with respect to tar, which is as follows. A leg of mutton is laid to roast, and whilst it is roasting it is basted with tar. Whilst the roasting is continued, a sharp skewer is frequently thrust into the substance of the mutton, so that the gravy may run out: with a mixture of the tar and gravy found in the dripping-pan, the body is to be anointed for three or four nights successively, and during the time the same linen is to be worn. This is alleged to be a remedy in several cases of lepra; and Dr. Cullen knew one instance of its having been employed in a lepra ichthyosis with great success; but he had no opportunities of repeating the practice.

But the chief use of tar is for paying the sides of ships and boats, and their rigging, in order to preserve them from the effects of the weather, which would otherwise crack or rot them.

The tar obtained from the deposition of pyroligneous acid has been recommended as the best preservative for every kind of wood-fence. For this purpose, it should be gently heated in an iron pot, and laid on with a brush. It soaks into the wood, and seems to leave no body, as the artists express it; but after some days' exposure to the sun, the surface and texture of the wood will be much altered; for it will be found so impervious and hard, that it will be very difficult to make any impression upon it. If a second, and especially if a third coat of this tar be put upon wood, it will then *bear out*, as the painters call it, sufficiently well; and Mr. Parkes is of opinion that it will preserve all outside wood-work much more effectually than any other means that have hitherto been employed for the purpose. For ornamental paling, and all outside work, a first, and perhaps a first and second coat of this tar might be used with great advantage; and when these are dry, white lead and oil might be used to finish the work. This substance not only hardens the wood, but effectually preserves it from worms and from all other insects. It will stop the progress of decay, when wood has become worm-eaten. It is observed, however, that this tar is very different from that which is distilled from mineral coal, but which the earl of Dundonald recommended for a similar purpose. The appearance of the application may be very considerably improved by the following preparations; viz. 1 gallon of tar, 1 oz. of tallow, 2 oz. of pulverized rosin, melted together and put on warm;—or, 1 gallon of the tar and 2 oz. of pulverized sulphate of iron, used as the other. This tar has also been found an useful varnish for articles made of rolled iron, or of cast-iron. A beautiful varnish for these purposes may be formed by intimately mixing in a gentle heat one gallon of the wood-tar with half a pint of rectified spirits of wine. If this be laid on hot and properly hardened, it will prove a beautiful and durable black varnish. Parkes's Chem. Ess. vol. ii.

Tar may sometimes be found useful as an application for cuts in sheep by clipping, and also to the parts affected by the fly; as well as in those of many other sorts of animals. It is likewise applied to the axles of wheel-carriages, in order to prevent friction, and might probably be still more beneficially made use of in this intention, by having a portion of black-lead incorporated with it, as it would last longer, and be, at the same time, more powerful in obviating the effects of friction.

It is a material which has also been recommended for being applied to the parts of trees from which boughs are taken; in which cases, the faces of the wounded parts and the edges of the bark are to be made perfectly smooth by means of a proper knife; and in a few hours afterwards, or as soon as the parts are become quite dry, they are to be carefully plaitered over with the tar, which is similar to that employed for smearing of sheep; or they may be laid over with white or blue lead paint, well mixed with oil, and made rather thicker than that commonly used in painting. The tar is, however, certainly preferable, being of a more adhering, healing nature; and, when laid on in a thin state, is not so apt to fall off in a scaly manner by the action and effects of the weather, as is the case with the other substances.

As the component parts of vegetable tar have been found to consist of oil, resinous matter, pyroligneous acid, and water; that which is of the finest brown colour, has the least acridity, and which is the freest from a dark black appearance, is probably the best and most proper for use in applications as dressings to animals; though the other kinds may be equally or more beneficial in different other intentions.

Tar, when in intimate mixture and union with butter or lard, and the different precipitates of mercury or sulphur, forms

TAR.

forms an excellent application in different diseases of various kinds of animals, especially those of the skin.

TAR, Barbadoes. See BITUMEN, and PETROLEUM Barbadoense.

TAR, Mineral. See BITUMEN.

TAR-Water. As the cold infusion of tar has been formerly much in vogue, and has been recommended by one of the most learned and ingenious writers of the age, it may not be improper to give some account of its virtues from the bishop of Cloyne's *Siris*, or chain of reflections concerning the virtues of tar-water.

In some parts of America, tar-water is made by putting a quart of cold water to a quart of tar, and stirring them well together in a vessel, which is left standing till the tar sinks to the bottom. A glass of clear water being poured off for a draught, is replaced by the same quantity of fresh water, the vessel being shaken, and left to stand as before. And this is repeated for every glass, so long as the tar continues to impregnate the water sufficiently, which will appear by the smell and taste.

But as this method produces tar-water of different degrees of strength, the author says he chuses to make it in the following manner: Pour a gallon of cold water on a quart of tar, and stir them thoroughly with a ladle or flat stick, for the space of three or four minutes; after which the vessel must stand eight-and-forty hours, that the tar may have time to subside; when the clear water is to be poured off, and kept for use, no more being made from the same tar, which may still serve for common purposes.

This cold infusion of tar hath been used in some of our colonies as a preservative or preparative against the small-pox, which foreign practice induced the bishop to try it in his own neighbourhood, when the small-pox raged with great violence. He says the trial fully answered his expectation; all those within his knowledge, who took the tar-water, having either escaped that distemper, or had it very favourably. Several were preferred from taking the small-pox by the use of this liquor; others had it in the mildest manner; and others, that they might be able to take the infection, were obliged to intermit drinking tar-water. He says, he has found it may be drank with great safety and success for any length of time, and this not only before, but also during the afore said distemper.

The general rule for taking it is, about half a pint night and morning, on an empty stomach, which quantity may be varied according to the case and age of the patient; provided it be always taken on an empty stomach, and about two hours before or after a meal.

It has been found, that several persons infected with cutaneous eruptions and ulcers were immediately relieved, and soon after cured, by the use of this medicine. It is said, that even in the foulest distempers, it proved much more successful than salivations and wood-drinks had done. It also succeeded, beyond expectation, in a tedious and painful ulceration of the bowels, in a consumptive cough, and (as appeared by expectorated pus) an ulcer in the lungs, in a pleurisy and peripneumony. And when a person who had been for some years subject to erysipelatous fevers, perceived the usual forerunning symptoms to come on, the drinking of tar-water prevented the erysipelas.

Tar-water cures indigestion, and gives a good appetite. It is an excellent medicine in an asthma; it imparts a kindly warmth, and quick circulation to the juices, without heating, and is therefore useful, not only as a pectoral and balsamic, but also as a powerful and a safe deobstruent in cachectic and hysteric cases. As it is both healing and diuretic, it is very good for the gravel. The bishop says he

believes it to be of great use in a dropsy, having known it cure a very bad anasarca in a person whose thirst, though very extraordinary, was in a short time removed by the drinking of tar-water. From the success of this medicine in five or six instances, the bishop believes it to be the best and safest, either for preventing the gout, or for so strengthening nature against the fit, as to drive it from the vitals.

It may likewise be safely used in inflammatory cases; and, in fact, hath been found an admirable febrifuge, at once the safest cooler and cordial.

The salts and more active spirits of tar are got by infusion in cold water; but the resinous part is not to be dissolved thereby. Hence the prejudice which some, perhaps, may entertain against tar-water, the use of which might inflame the blood by its sulphur and resin, as a medicine, appears not to be well grounded. It is observed by chemists, that all sorts of balsamic wood afford an acid spirit, which is the volatile oily salt of the vegetable. Herein is chiefly contained their medicinal virtues; and this author affirms, that by the trials he has made, it appears that the acid spirit in tar-water possesses the virtues, in an eminent degree, of that of guaiacum, and other medicinal woods.

It is certain tar-water warms, and therefore some may perhaps still think it cannot cool. The more effectually to remove this prejudice, let it be farther considered, that, as on one hand, opposite causes do sometimes produce the same effect; for instance, heat by rarefaction, and cold by condensation, do both increase the air's elasticity; so, on the other hand, the same cause shall sometimes produce opposite effects. Heat, for instance, in one degree thins, in another coagulates, the blood. It is not therefore strange, that tar-water should warm one habit and cool another; have one good effect on a cold constitution, and another good effect on an inflamed one; nor, if this be so, that it should cure opposite disorders.

A medicine of so great virtue in so many different disorders, and especially in that grand enemy the fever, must needs be a benefit to mankind in general. There are nevertheless three sorts of people to whom the bishop says he would peculiarly recommend it; sea-faring persons, ladies, and men of studious and sedentary lives. See *Two Letters from the Bishop of Cloyne, &c.* published in 1747.

If it be asked, what precise quantity, or degree of strength, is required in tar-water? It is answered, that the palate, the stomach, the particular case and constitution of the patient, the very season of the year, will dispose and require him to drink more or less in quantity, stronger or weaker in degree. Precisely to measure its strength by a scrupulous exactness, is by no means necessary.

It is to be observed, that tar-water should not be made in unglazed earthen vessels, these being apt to communicate a nauseous sweetness to the water.

The same ingenious author recommends tar-water in the plague, and for the distemper among the horned cattle; with what success, must be left to experience.

Though this medicine, says Dr. Lewis, is undoubtedly very far inferior to the character that hath been given of it, it is apparently capable of answering important purposes, as a deobstruent balsamic solution, moderately warm and stimulating. It sensibly raises the pulse, and increases either perspiration or the grosser evacuations. He adds, "I have been informed of some late instances of its good effects in disorders of the leprous kind." *Mat. Med.*

Dr. Cullen thinks that the acid principle gives the virtue to tar-water, and on this account the bishop of Cloyne properly preferred the Norway tar to that of New England, as the former contains more acid than the latter. This eminent

physician acknowledges that he found this preparation in several cases to be a valuable medicine; and that it appeared to strengthen the tone of the stomach, to excite appetite, to promote digestion, and to cure all symptoms of dyspepsia. At the same time, it manifestly promotes the excretions, particularly that of urine. From all these operations, it will be obvious, as the doctor thinks, that in many disorders of the system this medicine may be highly useful. Lewis. Woodville.

It has been lately observed by Dr. Darwin, that the watering of ground with tar-water is capable of destroying the white slug, which is so highly destructive to vegetables.

TAR-Kettle, in *Rope-Making*, is made of copper, and holds from ten to twenty barrels of tar. It is set in strong brick-work, and over it is fastened, from side to side, in the direction of the nipper, a bridge, made of three-inch oak-plank, thirteen inches broad, through the middle of which is a mortise for the step to go through, to keep the yarn down and clear of the bottom, when drawing through the kettle. On the side of the kettle next the capstern, is an upright post, twelve inches square, in which is fixed a nipper to press the tar out of the yarn; and a staff, with a weight suspended at the end, is fixed on the side of the nipper to keep it down, that the yarn may imbibe no more tar than is necessary.

TAR-Rope, a term used to signify tarred rope, or rope-yarn, such as the thread of old cables, &c. This sort of tar-rope is useful for a great number of different purposes, such as those of tying up the wads or sheaves of beans in the field, and many other similar articles; the fastening of plants and trees to various kinds of supports; and for being applied to a variety of other little uses of the more domestic kind, as being cheap and readily procured.

TAR, in *Commerce*, a small silver coin on the coast of Malabar.

TAR, in *Sea Language*, a figurative expression for a sailor of any kind.

TARA, in *Geography*, a town of Russia, in the government of Tobolsk, on the Irtysh; 220 miles E.S.E. of Tobolsk. N. lat. 57°. E. long. 74° 43'.—Also, a town of Japan, in the island of Xicoco; 28 miles N.N.E. of Ocuti.

TARA Hill, a mountain of Ireland, in the county of Wexford, near the sea-coast; 4 miles N. of Newborough. See **TARAGH**.

TARA, the name of a simian hero renowned in the Hindoo epic the Ramayana, for mighty deeds in battle with the hosts of the tyrant Ravana, for the recovery of Sita, the ravished spouse of Rama.

TARAAN, in *Geography*, a town of Grand Bucharja; 50 miles E. of Samarcand.

TARABAD, a town of Hindoostan, in Baglana; 13 miles E. of Saler Mooler.

TARABE, in *Ornithology*, the name of a Brazilian parrot, larger than the common green parrot. Its general colour is green; but its head, breast, and the origin of its wings, are red; its beak and legs are of a dusky grey. Marcgrave. See **PITTACUS**.

TARACASSA, in *Geography*, a district of South America, in the vicerealty of Buenos Ayres, part of the jurisdiction of Carangas.

TARAE LAPIS, the name given by the writers of the middle ages to a stone which they say had the power of stopping all sorts of fluxes. They have left us no description of it, and it seems to have been lost even in their times; for they observe that the physicians used the *sanguis draconis*, or dragon's-blood, in its place.

TARAGH, in *Geography*, a small town or rather village

of the county of Meath, Ireland, on the noted hill of Taragh; where the states of Ireland are said to have assembled, and where some pretend that there was a magnificent palace belonging to the kings of Ireland; but as no trace of any such palace is to be found, its having existed must be regarded as improbable. General Vallancey accounted for there being no trace of it, by supposing it to have been made of mud and straw. A Danish invader is also supposed to have taken up his abode here, and to have built the fine Danish fort, or rath, on the south-east side of the hill, which is now beautifully planted. It is 5 miles N. by W. from Dunshaghlin, and 19 miles from Dublin, on the road to Cavan. There are two other hills of the same name, one in the county of Down, and the other in the county of Wexford, both of them near the sea.

TARAGOT, or **TARAGALE**, a town of Africa, in the country of Darah; 130 miles S.E. of Morocco.

TARAGUICO AYCURABA, in *Zoology*, the Brazilian name for a species of lizard, much approaching to the nature of the taraguira; but its tail is covered from its beginning with small triangular scales, and very regularly marked with four brown spots; the back also, particularly that part which is next the head, is variegated with undulated brown lines. Ray.

TARAGUIRA, the name of an American lizard. It grows to about a foot long; its body is rounded, and everywhere covered with small triangular dusky grey scales; its back is smooth, and it has not that false gullet under the throat which the iguana has.

This is the species of lizard of which it is reported, that it will wake a sleeping person, if it see him in danger of being bitten by a serpent. It is very common about houses and gardens in South America, and runs very swiftly, but with a waddling motion; and when it sees any thing at a distance, has an odd way of nodding its head very swiftly. Ray.

TARAGUPALA, in *Geography*, a town of Hindoostan, in Tellingana; 25 miles N.W. of Warangole.

TARAKLI, a town of European Turkey, in Bessarabia; 24 miles S.S.W. of Bender.

TARALEA, in *Botany*, a barbarous name of Aublet's. See **DIPTERYX**, species 2d.

TARAMA, in *Geography*, a jurisdiction of Peru, in the audience of Lima. The air is healthy, and the soil fertile.

TARAMAMON, a name given by Loubere to a ridge of mountains that passes E. and W. in Siam, not far to the north of Yuthia.

TARAMANDAHU, a river of Brasil, which runs into the Atlantic, S. lat. 30° 40'.

TARAMEH, AL, a town of Egypt, in ruins; 2 miles N.E. of Tineh.

TARAMUNDE, a town of Spain, in Asturia; 45 miles W. of Oviedo.

TARANCON, a town of Spain, in New Castile; 33 miles S.E. of Madrid.

TARANDUS, in *Entomology*, a species of *Lucanus*; which see.

TARANDUS, in *Zoology*, a name given by Agricola, and some other authors, to the rein-deer. See **CERVUS Tarandus**.

TARANIOLO, in *Ornithology*, a name by which the whimbrel, or small curlew, called the *arquata minor* by authors, is known in the markets of Italy.

TARANIS, probably from *taran*, thunder, in *Ancient Mythology*, a name given by the Gauls to Jupiter, under which appellation they sacrificed human victims to him.

Taranis corresponded to the Jupiter Tonans of the Romans. See THOR.

TARANNON, in *Geography*, a river of North Wales, which runs into the Severn; 4 miles W. of Newtown in Montgomeryshire.

TARANSA, one of the Western islands of Scotland, about four miles in length, and two in breadth, where widest, but in some places scarcely half a mile across; 5 miles N.E. from Toe-Head. N. lat. $57^{\circ} 52'$. W. long. $6^{\circ} 59'$.

TARANTA, the name of mountains of Abyssinia, that lie on the east of the kingdom.

TARANTARA, according to Ennius, the military trumpet's flourish of the Romans.

TARANTELLA, a rapid tune played to persons in Calabria, supposed to be bitten by the tarantula, in order to excite them to dance, which has been thought, while the disease was believed, to be the only specific.

TARANTISMUS, in *Medicine*, the disease or affection of those bit by the tarantula.

The patients under this malady are denominated *tarantati*.

Dr. Cornelio, in the Philosophical Transactions, represents this as an imaginary disease; and tells us, that the tarantati, or those that think themselves seized with it, (excepting such as for particular ends feign themselves so,) are most of them young wanton girls, such as the Italian writers call *Donne di sale*, who, falling from some particular indisposition, into melancholy madness, persuade themselves, according to vulgar prejudice, that they have been bitten by a tarantula.

But the evidence, on the other side of the question, has gained considerable credit, as will appear from the article TARANTULA.

TARANTOLA, in *Geography*, a town of Naples, in Abruzzo Citra; 10 miles E.N.E. of Sulmona.

TARANTULA, or TARENTULA, in *Natural History*, a venomous insect, whose bite gives name to a new disease, called *tarantismus*.

The tarantula is a kind of spider, the *aranea tarantula* of Linnæus, so denominated from the city of Tarentum, in Apulia, near which it is chiefly found. It is also called *phalangium Apulium*. Valetta, a monk of Apulia, who had always resided about the places where this mischievous animal is most frequent, and had many opportunities of tracing its several qualities, published a succinct, but very accurate history of it in the year 1706, under this name.

It has its name *phalangium*, from the three phalanges or joints of its legs, and this name equally suiting many other spiders, as well as this, it ceased to be its appropriated name, and was applied as a generical term to several other spiders of the larger kind, among which this species was always distinguished by the epithet *Apulian*, from the place where it was so frequently found.

The tarantula, or Apulian phalangium, is frequent in all parts of this country, in uncultivated places, but more especially it breeds most in sunny dry hills, and particularly in such parts of them as are exposed to the south.

It is said not to be found any where except in Apulia, but probably it is an inhabitant of many other places, though its poison may not be violent enough any where else to bring on the effects it does there: as we find in vipers and many other poisonous creatures, that the strength of their poison differs greatly in degree in different places.

M. Geoffroy says, that it is the opinion of some that the tarantula is never venomous but in the coupling season; and Baglivi says, that it is never so but in the heat of

summer; particularly in the dog-days, when, becoming enraged, it flies on all that pass by.

As this spider is very tender, and easily injured by cold winds and rain, it always digs itself a cave in the side of a hill for its habitation; and usually chuses for this purpose the hardest ground it can find, which is better able to defend it, and which it easily works into, with its forceps and claws. This always is hollowed upward in the hill, and by that means is safe from wet, all the water in rainy seasons running down over its top. Sometimes it burrows itself a cave in a valley or plain, but then it always chuses a dry, usually a chalky soil. In this case, the entrance into its cave is small, and within, there are several winding passages: if it happens to be surprized with wet in this place, from hard rains, it quits the floor and hangs by its feet against the top of the cave. It preys upon a number of small insects, with which the fields of Apulia abound, and seldom appears in the day-time, but creeps out about the time of sun-set, and preys at large upon the animals which are then betaking themselves to rest; without the danger it would be exposed to from its own enemies by day-light. If at any time he remains the whole evening in his cave or den, it is only to practise another method of hunting his prey. In this case, he comes forward to the mouth of the hole, and there lies in wait; his fore-legs are placed at the extremity of the hole, and his eyes have a clear view all round. The other insects are not aware of this trick, but as they walk near his hole he bursts out upon them, and seizing them, he conveys them into his habitation; where, as soon as he has eaten them, he retires back into his cell to dispose of the wings and other fragments, till he can carry them out at a more convenient time, and then places himself in his former posture for another prey.

The peasants of Apulia have a method of getting him out of his hole in the day-time, in order to destroy him. This they do by making a soft hissing noise through an oat straw: whether it be that the creature loves this sound, or rather that he takes it for the voice of some insect that he is used to prey upon, he always comes out, and falls a sacrifice to his greediness.

The creature has eight legs, and walks very well; his legs have each three joints, and are covered with a fine downy hairiness; they are of a whitish colour at the bottom, and variegated with black lines, and are wholly black in their upper part, where they are joined to the breast: these all arise from a kind of oval shield, which is placed upon the breast, and is black, hairy, and very hard: this is called by some the *speculum* of the tarantula. From the shoulders there grow a pair of horns, at least they are usually called so, though they seem much better to deserve the name of *arms*; the use of these is to hold fast the prey, that it may not be able to escape while he is killing it with his forceps: these horns or arms have the same number of joints that the legs have, but they greatly differ from the legs, in that they are shorter, and of a yellowish colour; they are also covered with a longer and thicker hair, for the more certainly holding the prey, and are terminated by black claws, and they are much smaller and more capable of motion every way. The belly is either white, or of a pale yellow, and is marked with a transverse black streak: this is surrounded with several other small spots of the same colour, and is clothed with a very fine and short down; the whole body beside is covered with longer hairs, and is of a whitish or brownish colour; the apex of the head, the shield of the breast, and the ends of the forceps, are as hard as a crab's claws; but the rest of the body is covered with a tender supple skin: the eyes are

TARANTULA.

very large, and of a fine shining black; they are continually in motion, and, when seen in the night, or in a dusky place, they shine like the eyes of a cat. In the place where the mouth is placed in other animals, there arises in this a black hard forceps; the upper part of this instrument is covered with a yellow hairiness, and it is terminated by extremely fine and sharp claws, which the creature can open or close up at pleasure. While the arms hold the prey in a proper position, these sharp points make wounds in the body, and the other parts of the forceps squeeze the body till all its juices are pressed out, and the creature feeds on them: the mouth is placed much below these, and stands exactly in the proper place to receive the juices expressed by this operation. The tarantula sleeps in his cave the whole winter, and a great part of the autumn and spring; and if during this time he is ploughed up, as is often the case, or is any other way taken out of his hole, he is found quite torpid and numbed, and is unable to do any mischief by biting.

The hole or mouth of a tarantula's cave always gives some idea of the size of the creature within: he makes it small if he enters it while young; and as he grows larger, he eats away more and more of the earth to widen it still more, so that the diameter of it is usually about equal to the diameter of the body. The size of a chestnut is about the standard of a full-grown tarantula; but there are some old ones found much larger and more hairy. The female is known from the male by having longer legs and a larger belly. They copulate in June and July, and at that season the females are often met with in the fields carrying the males upon their backs. In August and September they lay their eggs, which remain the whole winter; and in the summer after are hatched.

Pliny tells a story of the young ones always eating up their mother for the first food, which is countenanced by the relation of the peasants in those parts, who say that they all swarm about her and suck her juices from many places at once, till they leave her a lifeless carcase on the field, and then go each their several ways in search of other food. The bite of the tarantula, as it is called, is not properly a bite, but a wound inflicted in a very peculiar manner. The creature pierces the skin with its forceps, and at that instant injects from its mouth a poison into the wound. The time in which their wounds are fatal, is that of their copulation; at this time they are in their utmost vigour and power of hurting. People of fashion are rarely hurt by them, but principally the poor labourers, who sleep half naked in the field, and the women who travel the country with naked feet, gathering medicinal herbs.

The bite occasions a pain, which at first seems much like that felt on the stinging of a bee, or an ant: in a few hours the patient feels a numbness, and the part affected becomes marked with a little livid circle, which soon after rises into a very painful tumour; a little after this he falls into a profound sadness, breathes with much difficulty, his pulse grows feeble, and his senses fail; at length he loses all sense and motion; and dies, unless relieved. But these symptoms come somewhat differently, according to the nature of the tarantula, and the disposition of the patient. An aversion for black and blue; and, on the contrary, an affection for white, red, and green; are other of the unaccountable symptoms of this disease.

All the assistance medicine has been able to discover by reasoning, consists in some surgical applications on the wound, and in cordials and sudorifics; but these are of little efficacy: a thing that avails infinitely more, is, what reason could never have discovered—music.

As soon as the patient has lost his sense and motion, a musician tries several tunes on an instrument; and when he has hit on that, the tones and modulations of which agree with the patient, he is immediately seen to make a faint motion: his fingers first begin to move in cadence, then his arms, then his legs, by degrees his whole body; at length he rises on his feet, and begins to dance; his strength and activity still increasing. Some will continue the dance for six hours without intermission.

After this he is put to bed, and when he is judged sufficiently recruited from his first dance, he is called out of bed, by the same tune, for a second.

This exercise is continued for several days, six or seven at least; in which time the patient finds himself exceedingly fatigued, and unable to dance any longer; which is the characteristic of his being cured; for as long as the poison acts on him, he would dance, if one pleased, without any discontinuance, till he died of the mere loss of strength.

The patient, on this, perceiving himself weary, begins to come to himself; and awakes as out of a profound sleep; without any remembrance of what had passed in his paroxysm, not even of his dance.

Sometimes the patient, thus recovering from his first access, is quite cured; if he be not, he finds a melancholy gloom hanging on him; he shuns the sight of men, and seeks water; and, if he be not carefully looked to, throws himself into some river. If he do not die, the fit returns at that time twelvemonth, and he is driven to dancing again. Some have had returns regularly for twenty or thirty years.

Every tarantula has his particular and specific tune; but, in the general, they are all very brisk, sprightly ones, that work cures.

This account was given in the Royal Academy of Sciences, by M. Geoffroy, at his return from Italy, in 1702, and confirmed by letters from F. Gouye. The like history is given by Baglivi, in an express dissertation on the tarantula, published in 1696.

Authors are divided about the nature of the poison of the tarantula. Cardan says it is a cold one, and Scaliger says it is a hot one; but, be this as it will, Valetta informs us, that its effect is very sudden; it is no sooner received into the flesh, but the veins take it up and carry it to the heart, where it becomes diffused through the whole mass of blood, and gives an immediate trembling of the limbs, and a difficulty of breathing. The next part it seizes is the brain, where it produces different effects in different subjects; and, according to their state of health, and the condition of their juices, brings on various species of phrensies. The patient sees a thousand phantoms, sometimes all jovial and merry ones, and sometimes imaginary scenes of blood and cruelty. Some are fond of seeing little streams of water trickling down into a basin; others are never easy unless they have green leaves before them: this indeed is almost an universal symptom. Some are delighted with various colours, and some are fond of violent motion, such as dancing, leaping, and the like; and some are in love with slow and graceful movements, as walking majestically, bowing, and dancing slow dances. Some are military mad, and call out for the noise of drums and trumpets, and the clashing of swords; but all of them, as well the brisk and noisy, as the lethargic and dull, are pleased with music.

They will get up and dance to any instrument; and the moment it ceases playing, they will fall down to the ground as if apoplectic, and not stir again till the music is renewed. Many people have laughed at the whole history of the bite of a tarantula, from this one accident of its poison being cured

cured by music; but all who have been upon the spot attest it. Valett. de Phaleng. Apulo.

To such extraordinary facts, it is no wonder a few fables should be added; as, for instance, that the patient is no longer infected than while the insect lives; and that the tarantula itself dances, all the while, to the same air with the person bitten.

Dr. Dominico Cirillo, professor of natural history at the university of Naples, positively contradicts the testimonies above recited. Having had an opportunity of examining the effects of this animal, in the province of Taranto, where it is found in great abundance, he affirms that the surprising cure of the bite of the tarantula by music, has not the least truth in it; and that it is only an invention of the people, who want to get a little money, by dancing when they say the tarantism begins. He makes no doubt but the heat of the climate contributes very much to warm their imagination, and to throw them into a delirium, which may be in some measure cured by music: but several experiments have been tried with the tarantula; and neither men nor animals, after the bite, have had any other complaint, except a very trifling inflammation on the part, like that produced by the bite of a scorpion, which goes off by itself without any danger at all. In Sicily, where the summer is still warmer than in any part of the kingdom of Naples, the tarantula is never dangerous, and music is never employed for the cure of the pretended tarantism. It is without doubt very extraordinary, says this writer, that a man of sense, and a physician of great learning, as Baglivi was, should have been satisfied with the account of this disorder; and that, instead of examining the facts by experiments, he should rather have tried to explain it: but even philosophers like very much to meet with wonderful and extraordinary things, and though they are against all reason, still they want them to be true, and endeavour to find out the cause of them. Every year this surprising disorder loses ground; and he is persuaded, that in a very little while it will entirely lose its credit. The Neapolitan physicians all look upon the tarantula in the same light, particularly after the ingenious book published on this subject by the learned Dr. Serao; who, by various experiments, has proved, that the bite of the tarantula never produced any bad effects, and that music never had any thing to do with it. Phil. Transf. vol. ix. art. 22.

The bite of the tarantula, and the method of its cure, were, however, for many years subjects of elaborate discussion; and different theories were proposed for explaining them, some account of which it may not be improper to preserve.

Theory of the Tarantula's Bite, by M. Geoffroy. The poisonous juice injected by the tarantula, M. Geoffroy conceives, may give the nerves a degree of tension greater than is natural to them, or than is proportionate to their functions: and hence may arise a privation of knowledge and motion. But, at the same time, this tension, equal to that of some strings of an instrument, puts the nerves in unison to certain tones, and obliges them to shake, after being agitated by the undulations and vibrations of the air proper to those tones. And hence this wonderful cure by music: the nerves, thus restored to their motion, call back the spirits thither, which before had abandoned them.

It may be added, with some probability, and on the same principles, that the patient's aversion for some colours arises hence, that the tension of his nerves, even out of the paroxysm, being still different to what it is in the natural state, the vibrations those colours occasion in the fibres of the brain,

are contrary to their disposition, and occasion a kind of dissonance, the effect of which is pain.

Theory of the Effects of the Tarantula's Bite, by Dr. Mead. The malignity of the poison of the tarantula seems to consist in its great force and energy, whereby it immediately raises an extraordinary fermentation in the whole arterial fluid, by which its texture and crasis are considerably altered: the consequence of this alteration, when the ebullition is over, must necessarily be a change in the cohesion of its parts, by which the globules, which did before with equal force press each other, have now a very differing and irregular nifus, or action; so that some of them do so firmly cohere together, as to compose moleculeæ, or small clusters: upon this account, as there is now a greater number of globules contained in the same space than before, and the impulse of many of these, when united together, differing according to the conditions of their cohesion, as to magnitude, figure, &c. the impetus with which this fluid is driven towards the parts, will not only be seen at some strokes greater than ordinary, but the pressure upon the blood-vessels must be very unequal and irregular; and this will be particularly felt in those which are most easily distended, as those of the brain, &c.

Upon this, the nervous fluid must necessarily be put into various undulatory motions, some of which will be like those, which different objects, acting upon the organs or passions of the mind, do naturally excite in it; upon which such actions must follow in the body, as are usually the consequences of the several species of sadness, joy, despair, or the like determinations of thought.

This, in some degree, is a coagulation of the blood, which will, the more certainly, when attended with uncommon heat, as is the case in those countries where these creatures abound, produce such like effects as these: because the spirits separated from the blood thus inflamed, and compounded of hard, fixed, and dry particles, must unavoidably share in this alteration; that is, whereas their fluid consists of two parts, one more active and volatile, the other more viscid and glutinous, which is a kind of vehicle to the former; their active part will bear too great a proportion to the viscid; and consequently they must have more than ordinary volatility and force; and will, therefore, upon the least occasion imaginable, be irregularly determined to every part.

Whereupon will follow tremblings, anger, or fear, upon a light cause; extreme pleasure at what is trivial, as particular colours, or the like; and, on the other hand, sadness at what is not agreeable to the sight; nay laughter, obscene talk and actions, and such other symptoms as attend persons bit; because, in this constitution of nervous fluid, the most slight occasion will make as real a reflux and undulation of it to the brain, and present as lively species there, as the strongest cause and impression can produce in its natural state and condition: nay, in such a confusion the spirits cannot but sometimes, without any manifest cause at all, be hurried towards those organs, to which, at other times, they have been most frequently determined; and every one knows which these are in hot countries.

The effect of music on persons touched with this poison confirms the doctrine above delivered. For muscular motion, we know, is no other than a contraction of the fibres, from the arterial fluid's making an effervescence with the nervous juice, which, by the light vibration and tremor of the nerve, is derived into the muscle.

Thus there is a twofold effect and operation of the music, that is, upon the body and the mind: a brisk harmony excites

eites lively species of joy and gladness, which are always accompanied with a more frequent and stronger pulse, or an increased impulse of the liquor of the nerves into the muscles; upon which suitable actions must immediately follow.

As for the body, since it was sufficient to put the muscles into action, to cause those tremors of the nerves, by which their fluid is alternately dropped into the moving fibres, it is the same thing whether it be done by the determination of the will, or the outward impressions of an elastic fluid: such is the air; and that sound, which is the vibrations of it, is beyond dispute: these, therefore, rightly modelled, may shake the nerves as really as the *imperium voluntatis* can do; and, consequently, may produce the like effects.

The benefit of music arises not only from their dancing to it, and so evacuating by sweat a great part of the inflammatory fluid; but, besides this, the repeated percussions of the air hereby made, by immediate contact, shaking the contractile fibres of the membranes of the body, especially those of the ear, which, being contiguous to the brain, communicate their tremblings to its membranes and vessels: by these continued successions and vibrations, the cohesion of the parts of the blood is perfectly broken, and the farther coagulation prevented; so that the heat being removed by sweating, and the coagulation by the contraction of the muscular fibrillæ, the wounded person is restored to his former condition.

If any one doubts of this force in the air, he may consider, that it is demonstrated in mechanics, that the smallest percussion of the smallest body may overcome the resistance of any the greatest weight, which is at rest; and that the languid tremor of the air, which is made by the sound of a drum, may shake the largest edifices.

But, besides this, we must allow a great deal to the determinate force, and particular modulation of the trembling percussions; for contractile bodies may be acted upon by one certain degree of motion in the ambient fluid, though a greater degree of it, differently qualified, may produce nothing at all of the like effect. This is not only apparent in two common-stringed musical instruments, tuned both to the same height; but also in the trick which many have of finding the tone or note peculiarly belonging to any wine-glass, and, by accommodating their voice exactly to that tone, and yet making it loud and lasting, make the vessel, though not touched, first to tremble, and finally to burst; which it will not do, if the voice be either too low, or too high.

This makes it no difficult matter to conceive, why different persons, infected with this sort of venom, do require a different sort of music, in order to their cure; inasmuch as the nerves and dilatable membranes have different tensions, and consequently are not all alike to be acted upon by the same vibrations.

TARANTULA, in *Zoology*, is also the name given by the Italians to a peculiar species of lizard, called by Aldrovand, and some others, *lacertus facentus*.

It is of a grey colour; its skin is extremely rough; and it is thicker and rounder bodied than the other lizards. It is found, like our common cft, under old walls, and among the ruins of buildings, particularly in the neighbourhood of Rome, in great plenty; its colour looks dead and ghastly, and it is as odious to the sight among the Italians, as the toad is with us, being never seen without a sort of natural horror. It is esteemed also a poisonous creature, as the toad is with us; though it is not easy to find well-attested stories of any body's ever having been hurt either by the one or the other of these creatures. Ray.

TARAPACA, in *Geography*, a town of Peru, in the bishopric of Arequipa, on a river which soon after runs into the Pacific ocean, S. lat. 20° 10'.

TARAPILLY, a town of Hindoostan, in Coimbatore; 20 miles N.E. of Damiccotta.

TARARE, a town of France, in the department of the Rhône and Loire; 18 miles W.N.W. of Lyons.

TARAS, in *Ancient Geography*, a small river of Italy, which passed to Tarentum, and probably gave it its name.—Also, a river of Italy, in Japygia.—Also, a river of Epirus.—Also, a town of Asia Minor.—Also, a river of Scythia.

TARAS, in *Geography*, a town of the duchy of Wurzburg; 2 miles N.W. of Hasfurt.

TARASCO, in *Ancient Geography*, a town of Gallia Narbonnensis, on the left of the Rhone, and west of Arlate.

TARASCON, in *Geography*, a town of Spain, in New Castile; 22 miles S.W. of Huete.—Also, a town of France, and principal place of a district, in the department of the Mouths of the Rhône, on the Rhône, with a castle, fortified in the ancient manner. It is situated opposite Beaucaire, with which it communicates by means of a bridge of boats. The number of inhabitants is about 7000; 3 posts E. of Nîmes. N. lat. 43° 48'. E. long. 4° 44'.—Also, a city of France, and capital of the department of the Arriege, on the river Arriege. In it are several manufactures of iron; 48 miles S. of Toulouse. N. lat. 42° 50'. E. long. 1° 41'.

TARASOVA, a town of Russia, in the government of Irkutsk, on the Lena; 12 miles S. of Tutura.

TARATATO, a town on the east coast of Fortaventura, one of the Canary islands.

TARAUMARA, a large province of North America, in the north-east part of New Biscay, bounded on the west by Sonora, on the east by New Mexico, its limit being the Rio Bravo. On the south-west it borders on Cinaloa. Alcedo computes the extent at 100 Spanish leagues from east to west, and as much from north to south. This province was discovered in 1614, and derives its name from a savage nation found there, of pacific dispositions. This province contains 48 pueblos, or villages, or stations of Franciscan missionaries, exclusive of the capital of St. Felipe de Chiguaga. It is chiefly rich in mines, the minerals being smelted at the Real, or royal station of St. Eulalia, or probably the Real Nueva in the maps, in N. lat. 29° 36'.

TARAXACUM, or TARAXACON, in *Botany*, a name used by the Arabians, supposed by Ambrosini to have been derived from the Greek *ταραχος*, *catable*, because the plant to which it was applied, (our Dandelion, or something nearly akin,) was used for food. De Theis derives it, with more appearance of probability, from *ταρασσω*, *to move*, or *trouble*, because of the laxative and diuretic quality of the plant in question, commemorated in its vulgar English, as well as French, appellation. See LEONTODON; at the end of which botanical article, we must observe, *genus of Leontodon* is printed by mistake for *gender*.

TARAXIPPUS, formed of *ταρασσω*, *I frighten*, and *ιππος*, *horse*, a kind of evil genius, the statue of which was erected in the Grecian hippodromes, in order to alarm and frighten the horses in their course. The shape and form of this strange deity are not described; but he certainly answered the end for which he was designed: it frequently happening, that the horses were so scared at his appearance, as to turn away with the utmost violence, and expose the lives of their riders or drivers to the most imminent danger. Many conjectures have been formed concerning this strange deity, and the means he used to frighten the horses: but the most probable

bable conclusion will be, perhaps, to suppose that some tricks and artifices were practised under the disguise of this figure, either with a design to render the victory more honourable in proportion to the difficulty of gaining it, or else that this horse-frightening deity was placed in the course as a touch-stone, to prove the resolution and temper of the horses; and to oblige the candidates to bring none into the field but such as by exercise and discipline were so assured and steady, as not to let their obedience be shaken upon the most trying occasions. Berenger's Hist. and Art of Horsemanship, vol. i. p. 54. See STADIUM.

TARAXIS, from *ταρασσειν*, to disturb, in Surgery, a slight ophthalmy, or inflammation of the eye. See OPH-THALMY.

TARAZ, in Geography, a river of Independent Tartary, which runs into the SIRR or Jaxartes at Otrur. Some suppose this to be the same with the river Tulas; but others represent it as a much more inconsiderable stream.

TARAZ, or Turkestan, a city of Asia, and capital of the country of Turkestan, situated on a small river which runs into the SIRR, 250 miles N. of Samarcand. N. lat. 44° 45'. E. long. 69° 42'.

TARAZONA, a town of Spain, in New Castile; 15 miles S. of Alarcon.—Also, a city of Spain, in Aragon, the see of a bishop, suffragan of Saragossa. This town is ancient, and was destroyed by the Moors in the year 724, and by the same people rebuilt in the beginning of the 12th century; 43 miles N.W. of Saragossa. N. lat. 42°. W. long. 1° 43'.

TARBA, in Ancient Geography, a town situated on the southern coast of the isle of Crete.

TARBASON, a word used by some chemical writers as a name of antimony.

TARBASSUS, in Ancient Geography, a town of Asia, in Pisidia.

TARBAT, in Geography, a town of Scotland, in the county of Cromarty. This parish originally belonged to the county of Ross, but was separated from it and annexed to Cromarty, in 1693; 6 miles E. of Tam.

TARBAT Ness, a cape of Scotland, on the east coast of the county of Ross, between the friths of Dornoch and Murray. N. lat. 37° 50'. W. long. 3° 40'.

TARBE, a city of France, and capital of the department of the Upper Pyrenées, built on the ruins of the ancient Bigorre: before the revolution it was the see of a bishop, and residence of a governor. It consists principally of one street along the Adour, and is defended by a castle; 7½ posts S. of Auch. N. lat. 43° 14'. E. long. 0° 8'.

TARBELLI, in Ancient Geography, a people of Gaul, in Aquitania, whose territory extended along the Aquitanic gulf.

TARBERT, in Geography, a post-town of the county of Kerry, Ireland, on the river Shannon, where there is a charter-school. It is 12½ miles S.W. from Dublin. There is also a small island of this name off the coast of Galway.

TARBIDO, or MARAZZO, a river of Naples, which runs into the Mediterranean, 13 miles S.W. of Cosenza.

TARBOU, a town of Hungary, on the river Theyfe; 14 miles N.N.E. of Kifwarda.

TARBURGH, or TARBOROUGH, a town of North Carolina, on the Tar; 45 miles N.N.W. of Newbern. N. lat. 35° 52'. W. long. 77° 44'.

TARBUT, a city of Persia, in Khorassan, eight furlongs distant from Turkish; with a population of about 8000 persons, defended by a strong wall, and flanked with towers. Provisions are here plentiful and cheap; it has 220 dependent

villages, and is possessed by Ifa Khan, a powerful chief, who can bring into the field an army of 10,000 men.

TARCHI, in Biography, a Neapolitan composer, who arrived in England in 1786, at the same time as Rubinelli. He was young at that time, but though he remained here only one season, he discovered considerable abilities, and seemed advancing rapidly into fame. He had fire, taste, and invention. If he still lives, we make no doubt but that he ranks high among the dramatic composers of his country.

TARCHONANTHUS, in Botany, so called from *tarcon*, or *taracon*, the Arabic name of *Artemisia Dracunculus*, our Taragon, and *ανθος*, a flower, because its flowers resemble those of that plant. Vaillant contrived this name in the Mem. de l'Acad. des Sciences, for 1719, but it is not one of his happiest.—Linn. Gen. 416. Schreb. 547. Willd. Sp. Pl. v. 3. 1792. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 515. Juss. 185. Lamarck Illustr. t. 671. Gært. t. 166.—Class and order, *Syngenesia Polygamia-aqualis*. Nat. Ord. *Compositæ Nucamentaceæ*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* turbinate, of one leaf, cut half way down into (for the most part) seven rather acute segments, coloured internally, shorter than the corolla, permanent. *Cor.* compound, uniform, of about twenty florets, all perfect, equal, each of one petal, funnel-shaped, with five teeth. *Stam.* in each floret, Filaments five, capillary, very short; anthers united into a cylindrical tube, as long as their own partial corolla, with a filamentous appendage at the base. *Pist.* in each floret, Germen inferior, oblong; style twice the length of the floret; stigmas two, divaricated. *Peric.* none, except the permanent calyx. *Seeds* solitary, ovate-oblong, compressed. *Down* woolly, investing every part of the seed. *Recept.* minute, clothed with woolly hairs, the length of the calyx.

Obf. The *seed-down* is very remarkable, as not crowning but entirely investing the seed. *Linneus*.

Eff. Ch. *Receptacle* villous. *Seeds* invested with hairs. *Common calyx* of one leaf, turbinate, cut half way down into several segments. *Anthers* spurred at the base.

1. *T. camphoratus*. Shrubby African Fleabane, or Aromatic Taragon-blossom. Linn. Sp. Pl. 1179. Suppl. 361. Willd. n. 1. Ait. n. 1. (*Elichryso affinis africana arborescens, floribus purpureo-violaceis, foliis Salviae, odore Rosmarini*; Herm. Lugd.-Bat. 228. t. 229. Pluk. Phyt. t. 174. f. 1.)—Leaves elliptic-oblong, nearly entire; densely downy beneath. Native of the Cape of Good Hope, from whence it was brought very early into the gardens of Europe. This is a greenhouse evergreen shrub, or small tree, flowering from June to October. The branches are angular, tuberculated, densely downy and hoary. Leaves scattered, stalked, two or three inches long, more or less acute, somewhat wavy, entire or minutely toothed; their upper side of a dark dull green, quite smooth, reticulated with fine veins; the under white and cottony, with a prominent rib and veins. When bruised they smell like rosemary, but less agreeably. *Panicles* terminal, many-flowered, with numerous lanceolate bracts, all together hoary, like the branches. Segments of the *calyx* from five to seven, or more. *Florets* dark dull purple, with whitish anthers. *Seeds* enveloped in copious white wool, like those of an *ERIOCEPHALUS*; see that article.

2. *T. ellipticus*. Oval-leaved Taragon-blossom. Thunb. Prodr. 145. Willd. n. 2.—“Leaves elliptical, finely toothed; densely woolly beneath.”—Gathered by Thunberg at the Cape. We have seen no authentic specimen from him, but there are some in the Linnæan herbarium which answer to the

the specific character, though they are obviously a mere variety of the foregoing.

3. *T. racemosus*. Cluster-flowered Taragon-blossom. Thunb. Prodr. 145.—“Leaves elliptical, pointed, finely toothed; densely woolly beneath.”—From the same country. This is perhaps but another variety. The leaves of *T. camphoratus* vary in acuteness. Willdenow seems accidentally to have omitted this in transcribing. It should have been his n. 3.

4. *T. lanceolatus*. Lanceolate Taragon-blossom. Thunb. Prodr. 145. Willd. n. 4.—“Leaves elliptical, entire, smooth.”—Gathered at the Cape by Thunberg. His specific name is exceptionable, when compared with the characters of this and the rest of the species. We must rely on him for the synonyms of the following, it being his own discovery; or we should have presumed, without seeing specimens, that the plant before us might be *T. glaber* of Linnæus.

5. *T. dentatus*. Toothed Taragon-blossom. Thunb. Prodr. 145. Willd. n. 5. (*T. glaber*; Linn. Suppl. 360, according to Thunberg.)—“Leaves oblong, entire or toothed; slightly downy beneath.”—Gathered by Thunberg at the Cape. We have seen no specimen. Linnæus describes his plant as extremely like *T. camphoratus*, but quite smooth, and without any smell. It varies with narrower or broader leaves, sometimes entire, sometimes toothed.

6. *T. ericoides*. Heath-like Taragon-blossom. Linn. Suppl. 360. Willd. n. 6.—Leaves oblong, smooth, imbricated in four rows. Calyx in four deep segments.—Native of the Cape of Good Hope. A rigid shrub, with copious, round, irregular branches, whose points sometimes taper into a spinous point. Leaves like those of many *Erica*, minute, scarcely a line in length, elliptic-oblong, obtuse, entire, concave, smooth on both sides, dotted, aromatic when rubbed, imbricated in four rows on the very short, opposite, lateral shoots. Flowers solitary at the end of those shoots, each on a short silky stalk. They are erroneously termed “*conferti*” in the *Supplement*, being no otherwise crowded than because the little branches which bear them are so. Calyx in four very deep, elliptical, smooth, reddish divisions, very aromatic. Florets few, minute, concealed in the copious woolly hair, which is twice the length of the calyx.

Linnæus justly observes of this last species, that its genus is rather doubtful. We conceive it might as readily be supposed an *Eriocephalus*, and if the leaves could by any means be called filiform, we might guess it to be *E. glaber*, Thunb. Prodr. 168, a species not adopted in our account of that genus; (where Lamarek Illustr. t. 717, ought to have been quoted after Juss. 186.) The above conjecture is strengthened by Thunberg’s having mentioned no *Tarchoanthus ericoides*, nor, as far as we can discover, has he described the shrub in question under any other name. We beg leave to remark that the species of this whole genus, except the original one, are involved in much uncertainty, nor are the materials with which we are furnished sufficient to enable any botanist to form an opinion about them.

TARCHOANTHUS, in *Gardening*, contains a plant of the shrubby evergreen exotic kind, of which the species that is most commonly cultivated is the shrubby African fleabane, (*T. camphoratus*), which has a strong woody stem, that rises to the height of twelve or fourteen feet, sending out many woody branches at the top, which may be trained to a regular head.

Method of Culture.—This is a plant that may be increased

by cuttings, which should be planted out in the spring or early summer seasons, in pots filled with light mould, giving them shade and water occasionally. They soon strike root, and in three or four months may be potted off into separate pots, affording them shade and water as before, and placing them under shelter. They also strike root in the summer season, when planted in a common border, and covered with hand-glasses, and may in these cases be potted off in the autumn.

Afterwards they require the management of other hardy greenhouse plants. The plants do not produce ripe seeds in this climate.

They afford variety in these different situations.

TARDA AVIS, in *Ornithology*, a name given by many to the bustard, more commonly known among authors by the name *otis*.

TARDETS, in *Geography*, a town of France, in the department of the Lower Pyrenees; 6 miles S. of Mauléon.

TARDIGRADUS, or SLOTH, in *Zoology*. See BRADYPUS.

TARDO, in the *Italian Music*, is used to denote a slow movement, being much the same as *largo*.

TARDOIRE, or TARDOIERE, in *Geography*, a river of France, which runs into the Charente, near Rouchefoucault.

TARDOU, EL, a town of Spain, in the province of Cordova; 28 miles W. of Cordova.

TARDSONG, a town of Thibet; 250 miles E. of Lassa. N. lat. 29° 54'. E. long. 95° 34'.

TARE, in *Botany*. See VETCH.

TARE, in *Agriculture*, a well-known plant of the vetch kind, of which there are two sorts; the common purple-flowered spring or summer tare, and the purple-flowered wild or winter tare; the latter of which sort is by much the hardiest.

Numerous experiments in the culture of these different kinds of tares, were made by the Rev. Mr. Laurens, in order to ascertain their differences in hardiness, for which we refer to the Corrected Agricultural Survey of the County of Suffolk.

It is evident from the tall, close, hardy growth and succulent quality of the winter tare, that it must be a plant of much value to the farmer, as affording an abundant produce of green food for animals; and by being alternated with those of the gram kind, in ameliorating or preventing the exhaustion of the land that must otherwise take place. It has been suggested by the writer of the Agricultural Survey of the County of Middlesex, that it may be the means of enabling the arable farmer to support as much live-stock as the grazier, as while crops of this sort remain upon the ground, they afford larger supplies of the best kind of green food on the acre than the most rich and fertile grass lands; and they may be taken from the ground at so early a period in the summer season, as on the friable loamy soils to admit of a clean crop of turnips, &c. being obtained from the same land in the same year; and of those of the more heavy kinds being prepared and sown with wheat. And while they are capable of being raised with success on most sorts of soils and situations, they support and fatten cattle and sheep of different sizes and breeds in an expeditious manner. And further, they afford a good preparation for other sorts of green crops, and in that way keep up the succession of such sorts of food for the fattening of additional numbers of animals, and in that manner afford abundance of manure in situations where it could not otherwise be procured. On the

TARE.

the whole, he supposes, that by a judicious combination of this plant with those of turnips, clover, and sainfoin, the poor downs, sheep-walks, and other waste lands may be rendered from ten to thirty times more valuable than they are in their present state.

The tare in all its varieties is a plant which, in respect to soil, according to the author of the Present State of Husbandry, admits of considerable latitude, growing without difficulty or trouble on all the varieties, from that of the thin gravelly, to those of the deep and stiff clayey kinds, but flourishing in the most vigorous and perfect manner on those of the gravelly, loamy descriptions, that are not too moist or wet at particular seasons.

With regard to the preparation of the land for this sort of crop, there is less care necessary than for many other kinds of grassy sorts of crops, as it will succeed well where the soil has not been so much broken down, or reduced into fine mould; but it always grows in the most perfect and vigorous manner where a good degree of pulverization and fineness has been produced in the land by proper tillage. But in common, two or three ploughings, with occasional good harrowings in the intermediate times, may be fully sufficient for the purpose, at whatever season the crop is to be put into the ground.

As to the sowing of the seed of this crop, it has been observed, that as the seed of the spring tare does not succeed well when sown for the winter crop, nor that of the winter kind when put in for the summer produce, care should be taken to keep the seeds of the two sorts as perfectly distinct as possible. And that as they are, from their being both of nearly the same colour and size, as well as their agreeing in other particulars, extremely liable to be mixed in the seed-shops, it may be the best practice for the cultivator to preserve his own seed, as by that means he may not only be certain of having the seed good in its quality, but of the right sorts, and, of course, may depend more fully on his crops. And it has been suggested by the writer of the Middlesex Report on Agriculture, that steeping the seed in dry seasons may be of utility in promoting the quick vegetation of the crop in many situations of land and peculiarities of season. With regard to the quantity of seed that should be employed, it should, of course, vary according to the nature of the soil, and the time as well as manner of sowing. But from two bushels to two and a half are the proportions most commonly recommended in the broad-cast method of sowing. But on poor sorts of land, where the seed is sown late, and the climate is backward, three bushels may not be too much. And it has been also observed by a late writer, that where the crops are either to be cut for soiling, or to be fed down by live-stock, the proportion of seed should be considerably increased, as not only a greater produce is thereby provided, but the growth of the crops rendered more quick and full. In the drill method of sowing, when at the distance of six inches, two bushels of seed will be quite sufficient; and where the distances are larger, still smaller proportions of seed will answer the purpose.

In regard to the periods and manner of sowing these sorts of crops, it is evident that the former must vary with the intentions of the cultivator; but the winter sowings should be performed some time between August and October; and in exposed situations and poor soils, more early than in those of the contrary description. As for the spring sowings of these crops, they may be executed from the beginning of March to the end of April, or even earlier, with success. In some places, as on the down lands in Suffex, they find great advantage from sowing spring tares in June with a light mix-

ture of rape or cole seed, as about a quart to the acre, on the same land, as furnishing a good and nutritious feed for weaned lambs in the autumnal season.

With regard to the mode of sowing crops of this nature, it is mostly that of the broad-cast, which should be performed as evenly as possible over the surface of the well-prepared land; the seeds being afterwards well covered in by proper harrowing, in order to prevent their being picked up by birds, and to ensure their perfect vegetation and growth. It has been suggested, however, that in rich clean soil, it is probable the row method would succeed well with this sort of crop, as is the practice in some of the southern districts of the island, according to a late practical writer. And with some it has been the custom to sow a little rye with their winter tare crops, and a small quantity of barley with those of the spring, on which, however, it has been well observed, that as plants of different sorts never succeed well together, it is probable that little advantage can be derived from the practice, especially as the tare is not a plant that stands much in need of protection in the early stages of its growth, and may be injured by too much shade and closeness. The former of these sorts of seed, and some others, may, however, be occasionally blended with it, and sown as a good green feed for some sorts of young animals, as already noticed.

It has been suggested in the first volume of the Farmer's Magazine, that the most productive method of sowing this crop, when intended for feed, is to mix them amongst beans when drilled, at the rate of one firlof of tares to one boll of beans.

It is further stated, however, as obvious, that when tares are intended for green food, there is no necessity for mixing them with beans. But that when such is the purpose, they require to be sown tolerably thick, so as the surface may be early covered; and if the ground is good, and recently dunged, an acre of them will afford as much keep for horses and cows, as can be gained from a full clover crop; at least the writer has found them fully as beneficial.

It has been found that crops of this sort are capable of being grown well after wheat or barley, but that they may be grown after almost any sort of crop where the land is in good heart, and properly prepared for the purpose.

In regard to the after-management of these sorts of crops, from their covering the land in a very complete manner, when they are sufficiently full, they do not require any great attention during their growth.

And in the process of making tare-crops into hay, more attention is found necessary than in those of most of the artificial grasses, as wet is more injurious to them, and they require more sun and air; but in other respects they demand the same cautious management, in order to prevent the foliage from being lost.

The most proper time for cutting for this purpose is, according to the author of the Synopsis of Husbandry, when the blossoms have declined, and the crops begin to fall flat on the ground. When well made, the hay is of the best and most nutritious quality or properties, being extremely useful in many intentions.

The writer of the Report of the State of Agriculture in Middlesex, states the produce as the result of experience, in having frequently weighed green tares, to be ten or twelve tons *per* acre, which is a large crop. And when made into hay, at about three tons the acre, which shews the vast disadvantage of making these crops into hay. The value of the produce, estimating it as if the whole were made into hay, being in that district from twelve to fifteen guineas the acre; and in situations where other sorts of hay sell at fifty shil-

TARE.

lings or three pounds, at from about seven pounds ten shillings to nine pounds the acre. And it is found that the spring tare-crops are lighter, and most liable to be injured by a dry season.

The produce in seed is likewise found to be considerable, being by some stated at from three to six sacks; but in other instances forty bushels or more have been obtained from the acre. It has been suggested, that this sort of seed is greedily devoured by pigeons, and that it may probably be used for poultry with advantage and profit, as being a very stimulant sort of food in the production of eggs.

In respect to the application of tare-crops, it has been well remarked by a late writer, that there can be little hesitation in pronouncing that of soiling them with horses or other sorts of live-stock on the farm, as the most advantageous and beneficial method of any which can be adopted for them.

It has, however, been advised by the author of the Agricultural Survey of the above district of Middlesex, that the farmer's stock should be wholly supported on them, from the time they begin to blow till the blossoms begin to fall off, and the formation of pods to take place. And, on account of the risk from wet, he advises that all the stock of a farm should be soiled on them green, as it will have the good effect of taking the stock off the grass land long enough to allow of its being mown for hay; and by this means the meadow-hay be much increased in quantity, and there will not be so much occasion for pasture, the tares abundantly supplying its place. And that besides, at the time the cattle return from green tares, the grass land in the mean time having been mown, may be ready to receive them. The same able writer remarks, in addition, that as it would be wasteful in the extreme to turn live-stock into a field of tares, as their treading and lying down would do great mischief to the crop, even by feeding it in small patches hurdled off; the most advisable method would be to mow the tares of the first half acre, and to carry the produce into the stables, cow-houses, and fold-yards, or on poor land, to be consumed by stock; then to hurdle the growing tares from such *cleared ground*, into which put the stock, and feed them all with the tares, given to them in racks, removing the hurdles and the racks forward daily to the edge of the growing tares; which will manure the land uniformly, and deposit all the urine in the soil. But the writer of the Corrected Gloucester Report on Agriculture, has stated another method of proceeding, where sheep are the sort of stock employed, which seems by no means ineligible, *viz.* to feed them through rack hurdles, which are made the same as the common five-railed ones, only leaving the middle rail out, and nailing upright pieces across, at proper distances, to admit the sheep to put their heads through. A swathe of vetches being mown in the direction you wish to plough the land, a sufficient number of these hurdles, allowing one to five sheep, are set up close to it: at noon, the shepherd mows the swathe and throws it to the hurdles, and the same at night: next morning, a swathe being first mown, the hurdles are again set, thus moving them once in the twenty-four hours. By this trifling additional trouble, the vetches are, it is said, eaten clean off, and the land equally benefited.

The writer of the Hertfordshire Corrected Agricultural Report remarks, that in the heavy land districts, he has found tares very generally cultivated for soiling the teams; a husbandry, he thinks, that cannot be too much commended. And he contends farther, that it appears by the writings of Ellis, that this branch of agriculture was common in this county above sixty years ago, before it was at all practised in many other counties, and he was glad to find it holds its place steadily in the management of the present period. It

is noticed, that Mr. Leach, of the same district, manures for tares, and that they are mown early, and then three earths are given to the land, when he gets good turnips after them. And that they are universal about Rickmanworth and Watford, many being fed off by sheep.

And the same writer says, in his Agricultural Survey of Norfolk, that the culture of this plant has increased very considerably in that district: within his memory they are multiplied at least tenfold. And that Mr. Overman there begins sowing winter tares about Michaelmas, once more before Christmas, and sometimes twice or thrice more, with spring tares for a succession. That after mowing, he does not plough the land, but runs sheep over it till the wheat-sowing. But that the cultivator who has made by far the greatest exertions in this husbandry that he ever met with, is Mr. Purdis, of Eggmore, who has 300 acres every year, feeding no more than is necessary to supply himself: they are fed by his sheep; used in soiling his numerous horses; and immense quantities made into hay.

It is suggested, as the remark of Mr. Blithe, that the sowing tares for summer-feeding sheep, is an absolutely new improvement in the husbandry of West Norfolk, and that he thinks it a very great and important one.

And in both the counties of Gloucester and Worcester, it is the practice to sow these crops as pasturage or feed for horses, and eat or get them off early enough to allow of turnips being sown the same season. But, as in the wet seasons, when the tare-crops are large, the stems are apt to become rotten upon the ground, and in this condition such food often proves prejudicial to the horses; in all such cases, it will be imprudent to cut or eat them any longer for the purpose of soiling in these ways.

It is noticed in the twenty-second volume of the *Annals of Agriculture*, that in the county of Suffex, these sorts of crops are of such use and importance, that not one-tenth of the stock could be maintained without them; horses, cows, sheep, and hogs, all feed upon them, the hogs are soiled upon them without any other food. This plant maintains more stock than any other plant whatsoever. Upon one acre, Mr. Davis, of this district, can maintain four horses in much better condition than upon five acres of grass. Upon eight acres he has kept twelve horses and five cows for three months without any other food. No artificial food whatever is equal to this excellent plant in his opinion.

They here find this crop to be a hearty and most nourishing food for all sorts of cattle. Cows give more butter when fed with this plant than with any other food whatsoever. And by having one crop of vetches succeeding another, Mr. Halstead, in the same county, insures a crop the whole summer of the best food that can be given to cattle; after this, he sows turnips, and then wheat.

In many of the southern counties, as Cornwall, Devon, Kent, and some others, the culture of this sort of crop might be greatly extended with vast advantage, especially if it were grown with the view of soiling different kinds of live-stock, to which purpose it is by far the best suited. Also, in many cases, as a highly valuable early sort of green spring feed for many kinds of young animals; the climates and soils being mild, and particularly favourable for their very early production and abundant growth, when sown at the most proper season.

It is remarked also, that they have on the South Downs an admirable practice in their course of crops, which cannot be too much commended, that of substituting a double crop of tares, instead of a fallow for wheat. Let the improving cultivator give his attention to this practice, for it is worth, in the opinion of the writer, a journey of five hundred miles.

They

They sow forward winter tares, which are fed off late in the spring with ewes and lambs: they then plough and sow summer tares and rape, two bushels and a half of tares, and half a gallon of rape; and this they feed off with their lambs in time to plough once for wheat. A variation is for mowing, that of sowing tares only in succession, even so late as the end of June for soiling. See SOILING.

TARE and Tret, in Commerce, any defect, waste, or diminution in the weight, the quantity, or the quality of goods.

The seller is usually to account to the buyer for the tare and tret.

Tare is more particularly used for an abatement, or deduction in the price of a commodity, on account of the weight of chests, casks, bags, &c. in which goods are put up, and whose weight may be known separately from that of the goods: and which being subtracted from the gross weight, or that of the cask, &c. and goods together, gives the weight of the goods alone, or the nett or neat weight. But if the tare is not known separately, and an allowance made for it at so much *per* hundred weight, or hundred yards, &c. then the deduction of the tare is by the rule of three.

Before the tare is taken off, the allowance called the *draft* or draught is subtracted from the original or gross weight of goods.

Tare is distinguished by a variety of denominations; thus: *Real* tare, or *open* tare, is the actual weight of the package; *customary* tare is an established allowance for the weight of the package; *computed* tare is an estimated allowance agreed upon at the time; *average* tare is when a few packages only among several are weighed, their mean or average taken, and the rest tared accordingly; *super* tare is an additional allowance or second tare, when the commodity or package exceeds a certain weight.

When tare is deducted, the remainder is called the *nett* weight; but if tret be allowed, it is called the *subtle* weight.

Tret is a deduction of 4 lbs. from every 104 lbs. of the *subtle* weight.

There was another allowance that was formerly made for dust or sand, or for the waste or wear of the commodity on foreign articles paid by the pound avoirdupois; but this is now nearly discontinued by merchants; or rather allowed in the price. It is wholly abolished at the East Indian warehouses in London, and neither tret nor draft is allowed at the custom-house.

The allowance called *tret* is calculated in the same way with tare. *Ex. 1.*—At 7 lbs. tare, or tret, to 112 lbs. gross, what is the tare, and also the nett weight, when 746 lbs. gross was received? say, as 112 lbs. to 7 lbs. so is 746 lbs. to the tare sought, which subtracted from 746 lbs. the remainder is the nett weight.

Ex. 2.—At 5 lbs. tret to 112 lbs. gross, what gross weight must be received, when 84 lbs. nett was paid for: and how much is allowed? subtract 5 from 112, then say, as 107, the remainder to 112, so is 84 to the gross weight sought; the difference of which and 84 is the allowance. Or thus: as 107 to 5, so is 84 to the allowance sought, which, added to 84, gives the gross weight sought. Thus from the gross weight, nett weight, and allowance, or any two of these in one case given, with any one of them in another case, we find the other two in that other case.

There are sometimes two allowances deducted out of the same quantity; first tare, and then tret: after the tare is deducted, the remainder is called particularly *subtle* or

subtle weight, out of which the tret is deducted, and the last remainder is called *nett* weight.

Ex. 3.—Tare being allowed at 4 to 112, and tret at 5 to 112, what is the nett weight in 87 lbs. gross? say, as 112 to 108 (= 112 - 4), so is 87 lbs. to the subtle; then as 112 to 107 (= 112 - 5), so is the subtle to the nett. And if you multiply 108, 107, and 87 continually, and also 112 by 112, and divide that product by this, the quotient is the nett weight sought. Malcolm's Ar. p. 564.

The tare is very different in different merchandizes: in some there is none at all allowed. It is a thing much more regarded in Holland than in England, or elsewhere: a modern author, M. Ricard, treating of the commerce of Amsterdam, observes, that the tares are one of the most considerable articles with which a merchant is to be acquainted, if he would trade with security.

Sometimes the tare is, as it were, regulated by custom; but generally, to avoid all dispute, the buyer and seller make a particular agreement about it.

For a comprehensive and accurate table of the custom-house and commercial allowances for various kinds of goods, we refer to the first volume of Dr. Kelly's "Cambist," our limits not allowing the insertion of it, though the liberality of the author would not object to our thus availing ourselves of his labours.

TAREEKAB, in *Geography*, a town of Candahar, on the Cameh; 23 miles E.S.E. of Cabul.

TAREF, a town of Arabia, in the province of Hedsjas; 25 miles N.E. of Medina.

TAREIBOIA, in *Zoology*, the name of a species of serpent found in America, and called also *cacaboia*; though, according to some authors, the tareiboia and cacaboia are two different species.

They are both of the amphibious kind, and live in lakes and waters, as well as on land; but they are not very poisonous. They are small snakes, and all over black; when offended they will bite, but the wound is curable. Authors have written differently of those serpents, some making the latter very different from the former, and of a yellow colour. Ray.

TAREINSKA, in *Geography*, a harbour of Kamtschatka, in Avatcha bay; 10 miles S. of St. Peter and St. Paul.

TAREIOU, a town of Brasil, in the government of St. Francisco; 160 miles S.W. of Fernambuco.

TAREIRA, in *Ichthyology*, the name of a fish caught in the American seas, and eaten, but of no fine flavour. It is of an oblong and thick body, gradually tapering toward the tail; its head resembles that of a snake, and is raised into two tubercles over the eyes; its eyes are yellow, with a black pupil; its nose pointed, and its mouth large and yellow within; it has extremely sharp teeth in both its jaws, and on its tongue; it has eight fins, the tail being accounted one, and this is forked; but this, as well as the rest, is of the consistence of a poppy-leaf, tender, thin, and soft, and sustained by soft rays; its scales are so nicely laid on one another, that it seems smooth to the touch; its belly is white, and its back and sides are variegated with longitudinal green and yellow lines. Marcgrave.

TAREIRI, in *Geography*, a river of Brasil, which runs into the Atlantic, S. lat. 6°. W. long. 34° 43'

TAREKA, in *Hindoo Mythology*, is the name of a fort of demon slain by Rama, in his warfare described in the Ramayana.

TAREM, in *Geography*, a city of Persia, in the province of Laristan, which is a meanly built place, situated in a

plain on the banks of a salt river. It consists of a mud fort, surrounded on all sides by wretched huts, formed of the branches of a date-tree, which grows in great abundance on the plain. It is the residence of many respectable merchants, who trade to Mascat, Gombroon, and Shirauz; and contains about 12,000 inhabitants; 30 miles N.N.E. of Lar, which is situated in N. lat. $27^{\circ} 30'$. E. long. $52^{\circ} 45'$.

TAREMDSONG, or TARENGASONG, a town of Thibet; 160 miles S.S.E. of Lassa. N. lat. $27^{\circ} 40'$. E. long. $92^{\circ} 50'$.

TARENT, a river of England, which runs into the Stour, in the county of Dorset, 3 miles S.E. of Blandford.

TARENT, an island of the Persian gulf, close to the shore, and immediately opposite to Ketif; although not so large, is a finer island than Bahrein. It is about seven miles long, and about as much in breadth, well supplied with good fresh water, and embellished with many delightful gardens, which produce fruits of various kinds in abundance.

TARENTEISE, *County of*, a province of Savoy, bounded north by the lordship of Faucigny, east by the duchy of Aosta, south by the county of Maurienne, and west by the duchy of Savoy; erected into a bishopric about the fifth century, and an archbishopric in the eighth. The kings of Burgundy erected it into a county; and towards the end of the eleventh century, Humbert II., earl of Maurienne and Savoy, became master of it, and his descendants held it afterwards. The soil is barren, and the aspect of the country, abounding with mountains and precipices, unpleasant, with little good land. The Isere crosses it from east to west. In its union with France, it formed part of the department of Mont Blanc.

TARENTO, a city of Naples, and province of Otranto, the see of an archbishop, situated on a small peninsula, which projects into a bay of the Mediterranean, to which it gives name. *Tarentum* (which see) was anciently the capital of a celebrated republic; but after undergoing many revolutions, it was destroyed by the Saracens or Hungarians: soon afterwards it was rebuilt in a new situation. After the total expulsion of the Greeks, duke Robert, the Norman, created his son, Bohemund, prince of Tarento; but his issue failing, it was bestowed on Henry, son of king Roger, and afterwards on William, a bastard of that family. It was wrested from him, on account of his illegitimacy, and conferred on Manfred of Swabia, who long bore the title of prince of Tarento. Its next transfer was made by Charles II. to his son Philip, titular emperor of Constantinople, by whose daughter it was conveyed to the house of Baux. Upon the failure of this family, it was obtained by Raymond Orsini, a younger son of the family of Nola. King Ladislaus, by marrying the widow of Raymond, became master of Tarento. Queen Joan II. gave it to her husband, the earl of La Marche; and he sold it to John Anthony Orsino Balzo, the right owner. When this prince died without issue, Tarento escheated to the crown. The inhabitants, neglecting the culture of the soil, directed their whole attention to fishing. Their number is estimated at 18,000. Its harbour, which was once excellent, is now so shallow as to admit only fishing boats. It is defended by a fort. The bay of Tarento is remarkable for springs of fresh water at the bottom, which, as it is said, may be taken up in a calm from the surface; 60 miles W.N.W. of Otranto. N. lat. $40^{\circ} 45'$. E. long. $17^{\circ} 10'$.

TARENTUM, in *Ancient Geography*, a town of Italy, in Magna Græcia, upon a small promontory of the Messapia. Tarentum was a very ancient city: some have ascribed its origin to the Cretans, before the Trojan war. In the 21st

Olympiad, a powerful body of emigrants arrived under Phalanthus from Laconia, that it seemed to be refounded. Here they settled upon an aristocratical plan, enlarged the fortifications of the city, and transformed it into a near resemblance of Sparta. Places were called by new names; and as most of the nobles had perished in a war with the Japyges, democracy was introduced. The favourable situation of this city, when it was first founded, contributed to its rapid prosperity. Placed in the centre of three seas, it obtained the whole commerce of the Adriatic sea, of the Grecian or Ionian sea, and of that portion of the Mediterranean called the Tyrrhenian sea. The adjacent country was fertile in grain and fruit; the pastures were excellent; the flocks afforded a very fine wool. It is no wonder, then, that the city should become rich, and that riches should be succeeded by luxury. Philosophy was not neglected at Tarentum; and that of Pythagoras gained the preference. The arts were also diligently cultivated. Strabo mentions the gymnasium of this city with high commendation, and the bronze colossus of Jupiter, which was scarcely inferior to that of Rhodes. Fabius Maximus found here abundance of pictures and statues, which served to adorn his triumph. With the wealth of Tarentum, its power also rose above that of all the colonies of Magna Græcia: its land forces were estimated at 32,000 foot and 3000 horse, in constant pay; and thirteen considerable cities acknowledged its dominion. At sea, their fleets rode triumphant and unrivalled. The most brilliant epoch of their history was that of the government of Archytas, whose profound learning as a philosopher, and skill as a mechanic, was no impediment to his political talents and exertions. His virtues also commanded respect. He frequently led the Tarentines to battle, and always returned after success. With Archytas, however, terminated the prosperity of Tarentum. At length this city partook of the horrors of those wars which desolated the southern part of Italy. The inhabitants not only exposed themselves to the Roman arms by some outrages committed against their ambassadors, but in the year 541 of Rome, Annibal having taken possession of Tarentum, the Romans sent against them a body of troops under Fabius Maximus, who retook it, and gained possession of its ample stores of wealth. In the year 664 or 665, it was made municipal; and in process of time, it became a very pleasant city. Whilst Totila was ravaging Italy in the year of Christ 546, the Greeks took possession of Tarentum, but suddenly abandoned it at the approach of a detachment of troops belonging to the king of the Goths; which event occurred in the year 548. In 552 the troops of Narfes retook it; but it was doomed to pass under the dominion of Romwald I., duke of Beneventum, in the year 668. On the decline of the Lombard power, the Grecian emperors regained possession of this country, and retained it till Robert Guiscard drove them for ever out of Italy. For its subsequent history, &c. see TARENTO.

TAREYEN, in *Geography*, a town on the west coast of the island of Ceylon. N. lat. $1^{\circ} 13'$. E. long. $119^{\circ} 12'$.

TAREYRAS, a town of Brasil, in the government of Goias; 75 miles E.N.E. of Villa Rica.

TAREZA, a river of Hungary, which runs into the Sáros, 20 miles S.W. of Tokay.

TARF, a river of Tunis, which runs into the Mediterranean, 3 miles S. of Maharefs.

TARFE, a town of Egypt; 7 miles W. of Cairo.

TARFOKIRAT, a town of the kingdom of Fez, on the coast of the Mediterranean; 22 miles W. of Melilla.

TARFOWA, a town of Africa, in Tunis, supposed to be

be the ancient Taphrura or Taparura; 24 miles W. of Thaince.

TARFVALA, a town of Sweden, in the province of Tavastland; 70 miles N.N.E. of Jamio.

TARGA, a sea-port town of Fez, near which is an oyster fishery; 90 miles S.E. of Tangiers.

TARGA. See TIRGA.

TARGAR, a name given by some of the chemical writers to oil of juniper.

TARGET, a shield; thus called from the Latin, *tergum*, back, because originally made of leather, wrought out of the back of an ox's hide.

TARGET is also the name of a mark for the artillery to fire at in their practice.

TARGET, in *Geography*, a town of France, in the department of the Allier; 2 miles S.E. of Montmarault.

TARGIONI, TOZZETTI, GIOVANNI, in *Biography*, an eminent Italian physician, was born at Florence in 1712, and took his degree of M.D. at Pisa, where he had studied and acquired singular reputation. Upon his return to Florence, he applied to the study of botany under the celebrated Micheli, who, at his death, bequeathed to him his library, herbarium, and MSS., and also the succession to his directorship of the botanical garden. He was likewise nominated professor of botany in the Florentine college by the grand duke; and admitted to the two academies of the Apatisti and Della Crusca. In conjunction with Cocchi, he engaged in making a catalogue of the library of Magliabecchi, which he had bequeathed to the public; and in recompence of his labour, the grand duke appointed him librarian. His various occupations, in connection with his practice, rendered it necessary for him to resign the office of director of the botanical garden in 1749. The mind of Targioni, however, was so active, that not content with his literary and professional employments at home, he made several scientific excursions, the result of which he published in his "Relazioni d'alcuni Viaggi fatti in diverse parte della Toscana per offerver le Produzioni naturali, e gli antichi Monumenti d'esse," Firenz. t. 1. 1751, 8vo. As a physician, he also published several pieces, and among these were "Directions for the Recovery of drowned Persons." He also promoted inoculation for the small-pox; and directed his attention to the treatment of epidemics, the draining of marshes, the prevention of the inundations of the Arno, and the examination of vegetables to be substituted for bread in a time of scarcity. Having taken leave of literary labours by a work on the progress of the physical sciences in Tuscany, comprehended in four volumes, he restricted himself to medical practice from the year 1770 to 1780. At length, in January 1782, being in his 71st year, his life terminated by a gradual decay. Haller. Gen. Biog.

TARGIONIA, in *Botany*, was so named by Micheli, in honour of his friend and fellow-labourer in the natural history of Italy and other parts of the world, Dr. Cyprian Targioni, of Florence, whose valuable museum he highly celebrates. There have been several persons of this name, distinguished at Florence, in medicine and natural history. John Targioni, who took the surname of Tozzetti for an estate, was professor of botany there, and died in 1782, aged 70. He published *Travels in Tuscany*, as well as several other works relating to natural science, and purchased the museum and library of MICHELI. (See that article.)—Mich. Nov. Gen. 3. t. 3. Linn. Gen. 565. Schreb. 764. Mart. Mill. Dict. v. 4. Sprengel in Stockholm Transf. for 1802. 85. t. 4: also in *Bullet. des Sciences*, 27. t. 2. f. 2. Juss. 8. Lamarck *Illustr. t. 877*.—Class and order, *Cryptogamia Hepatica*. Nat. Ord. *Alga*, Linn. *Hepatica*, Juss.

Gen. Ch. *Cal.*? Perianth a continued membrane, finely reticulated, enveloping the pistil, at length bursting. *Stam.*? Anthers numerous, roundish, sessile, scattered over the inside of the perianth. *Pist.* Germen oval, nearly sessile, accompanied at the base by the rudiments of others, with abortive styles; style terminal, awl-shaped, tubular, deciduous; stigma concave. *Peric.* Capsule sessile, nearly globose, of two hemispherical valves, bursting vertically, and one cell. *Seeds* very numerous, minute, roundish, connected by five threads into a dense globular mass.

Ess. Ch. Capsule globose, of two concave valves, and one cell. *Seeds* numerous, combined by fibres into a globe.

1. *T. hypophylla*. Dotted Targionia. Linn. Sp. Pl. 1603. Hudf. 519. Engl. Bot. t. 287. Dickf. Dr. Pl. 20. (*T. minima et vulgaris*; Mich. n. 1. Lichen petræus minimus, fructu orobi; Dill. Musc. 532. t. 78. f. 9. L. alter acaulis ἰσοβυλλοκαρπος; Column. Ecphr. part 1. 333. t. 331.)—Very common in heathy rather moist places, among mosses, on old walls and rocks, in moist parts of Italy. It is said also to have been found in Devonshire, and in Scotland. We have had living plants from a bank near Nayland in Suffolk, where the *Targionia* was discovered by the Rev. Mr. Kirby. The *fronds* are oblong, inversely heart-shaped, three quarters of an inch in length, growing nearly horizontally, in dense imbricated patches, attached by copious fine fibrous roots; their upper surface dark green, marked with a slight longitudinal furrow, and besprinkled with pale prominent points; the under side black, becoming visible when, by drought, the margins are curled in. The parts of the *flower* we have not seen. The *fruit* stands at the back of the frond, a little below the end, and looks like the seed of a vetch, being nearly globular, of a very dark brown, almost black; separating when ripe into two hemispherical valves, enclosing a globular mass of black powdery seeds, connected by fibres. The habit of the plant is exactly like that of a MARCHANTIA, (see that article,) but the generic character differs essentially, by the fruit alone, from that genus, as well as from JUNGERMANNIA, of which latter Hedwig suspected it to be a species. We rely on the observations of Sprengel for the structure of the flower, though without any solid conviction that the *anthers* are what he describes. The female parts of fructification resemble those of true MUSCI, (see that article,) but the *capsule* is totally different. This part is called *calyx* in the *English Botany*, from a supposed analogy to *Sphaerocarpus*, which we now believe to have little foundation. Whether there be any membrane extended from the base of the style over the germen, like the *calyptra* of mosses, does not appear from Sprengel's description, but it is highly probable; though as he expressly says the style itself is deciduous, that circumstance would still afford a material distinction.

TARGON, in *Geography*, a town of France, in the department of the Gironde; 6 miles N.E. of Cadillac.

TARGOWISKA, a town of Poland, in Volhynia; 9 miles S. of Lucko.

TARGUM, in the *Sacred Literature*, a name which the Jews give to their Chaldee glosses and paraphrases on the Scripture. See PARAPHRASE.

These Chaldee paraphrases, which were translations of the scriptures of the Old Testament, from the Hebrew text into the language of the Chaldeans, were called *Targums*: for the word *targum* signifies in Chaldee an interpretation or version of one language into another, and may properly be applied to any such version or translation; but it is most commonly by the Jews appropriated to these Chaldee paraphrases by way of eminence.

TARGUM.

As the Jews, during their long captivity in Babylon, had forgot their ancient language, the Hebrew; and now understood nothing but the language of their masters, the Chaldeans; there was a necessity of explaining the prophets in that language; and to this necessity is owing the first beginning of the Chaldee paraphrase.

To make the sense of the text understood, each doctor made a paraphrase of some part of it in the vulgar tongue; and as these several interpretations, in time, became very voluminous, certain rabbins undertook to collect them together; and this collection they called *The Targum*.

The Jewish doctors do not agree about the antiquity of the Targum; for the more modern Jews having blended their own comments with those of the ancients, no certain age or era can be fixed for the whole work.

It is commonly believed, that R. Jonathan, who lived under the reign of Herod the Great, made the first Chaldee version of the prophets; and with this version mixed the interpretations borrowed from tradition. Onkelos, it is certain, translated the Pentateuch almost word for word; and without any paraphrase; and another version of the Pentateuch is ascribed to Jonathan, but that without much certainty.

Dr. Prideaux thinks, that the version or Targum of Onkelos is the most ancient of all that are now extant: and the principal reason of his adopting this opinion is, that the style in which it is written approaches nearer to the style of that part of Daniel and Ezra, which is written in the Chaldee language, and which may be considered as a standard of its purity, more than any other. This Targum has been held in higher esteem among the Jews than all the other Targums, and being set to the same musical notes with the Hebrew text, it is thereby made capable of being read in the same tone in their public assemblies. The next to this in the purity of its style, is the Targum of R. Jonathan Ben Uzziel on the prophets; that is, on Joshua, Judges, the two books of Samuel, the two books of Kings, Isaiah, Jeremiah, Ezekiel, and the twelve minor prophets. The Targum of Onkelos is a strict version, rendering the Hebrew word for word; whereas Jonathan takes the liberty of a paraphrase, by enlargements and additions to the text. The third Targum, or that on the law, ascribed to Jonathan, is not his, because the style of it is wholly different from that of his true Targum on the prophets, and several things are mentioned in it, which had no being, or at least no name, till after Jonathan's time. The fourth Targum is on the law, written by an unknown author, and at an unknown period. It is called the *Jerusalem Targum*, probably because it was written in the Jerusalem dialect, which was spoken by the Jews after their return from Babylon, and which contains a mixture of Hebrew words with the Chaldee. This Jerusalem Targum is not a continued paraphrase, as all the rest are, but confined to select passages, as the author seems to have thought the text most wanted an explication. In many places it is taken word for word from the Targum, said to be Jonathan's on the law: and contains several things, which are delivered in the same words in the New Testament by Christ and his apostles. Dr. Prideaux accounts for this circumstance, by supposing that these were sayings and phraseologies, which had obtained among the Jews in the time of our Saviour, and continued among them long after: and hence Christ and his apostles, and afterward the author of this Targum, derived them from the same source. The fifth Targum, which is that on the Megilloth, *i. e.* Ruth, Esther, Ecclesiastes, Solomon's Song, and Jeremiah's Lamentations; the sixth, which is the second Targum on Esther; and the seventh,

which is that on Job, the Psalms, and the Proverbs, are all written in the most corrupt Chaldee of the Jerusalem dialect. Of the two former, no author is named; but the author of the third is said to be Joseph the one-eyed, but who he was, or when he lived, we are not told: that on the Megilloth, which mentions the *Mischna* and the Talmud with the explication, must have been written after the Babylonish Talmud, or the year of Christ 500. The eighth and last of these Targums, is that on the two books of Chronicles; published by Beckius at Augsburg in Germany, that on the first book in 1680, and that on the second in 1683. On Ezra, Nehemiah, and Daniel, there is no Targum.

That the Targum of Onkelos on the law, and that of Jonathan on the prophets, are as ancient as our Saviour's time, if not more ancient, is the general opinion of both Jews and Christians. As to all the other Targums besides these two, they are certainly of a much later date; the style of every one of them is more barbarous and impure than that of the Jerusalem Talmud, and they must, therefore, have been written after the composition of that work, *i. e.* after the beginning of the fourth century after Christ; and if the Talmudic fables, with which they abound, were taken out of the Babylonish Talmud, this will bring their date still lower, and prove them to have been written after that Talmud, or after the beginning of the sixth century after Christ.

The Targums of Onkelos and Jonathan are in such great esteem among the Jews, that they hold them to be of the same authority with the original sacred text, and for the support of this opinion, they feign them to be derived from the same fountain. The Chaldee paraphrase of Onkelos, they say, was delivered in the same manner with the real law, when God gave the written law unto Moses at Mount Sinai; and when by his holy Spirit he dictated to the prophets the prophetic books, he delivered severally to them upon each book the Targum of Jonathan at the same time. These were delivered by faithful hands, the first from Moses, and the other from the prophets, till they came down to Onkelos and Jonathan, who only put them into writing.

Agreeably to the high opinion that was entertained of them, they were read every Sabbath-day in their synagogues, in the same manner as the original sacred word itself, of which they were versions; and this use of them was continued to late times. Whether the Targums of Onkelos and Jonathan were received for this use so early as our Saviour's time is not certain; however, it seems that these, or some others, were used for the instruction of the people, and were read among them in private as well as in public. Agreeably to this purpose, they had some of their bibles written out in Hebrew and Chaldee together; that is, each verse first in Hebrew, and then in Chaldee; and thus from verse to verse through the whole volume. In these bibles, the Targum of Onkelos was the Chaldee version for the law; and that of Jonathan for the prophets; and for the Hagiographa, the other Targums that were written on them. One of these bibles, thus written, Buxtorf tells us he had seen at Strasburg: and bishop Walton acquaints us, that he had the perusal of two others of the same sort, one in the public library of the church of Westminster, and the other in the private study of Mr. Thomas Gataker. The other Targums are all of a much later date than those of Onkelos and Jonathan, and of far less authority: however, bishop Walton has introduced most of them into his Polyglot. The Targums of Onkelos and Jonathan are of great use for the better understanding not only of the Old Testament, on which they are written, but also of the New. As to
the

the Old Testament, they serve to vindicate the genuineness of the present Hebrew text, by proving it to be the same that was in use when these Targums were made, contrary to the opinion of those who think the Jews corrupted it after our Saviour's time. They help to explain many words and phrases in the Hebrew original, and they hand down to us many of the ancient customs of the Jews. And some of these, with the phraseologies, idioms, and peculiar forms of speech, which we find in them, do in many instances help as much for the better illustration and better understanding of the New Testament as of the Old: the Jerusalem Chaldee dialect, in which they are written, being the vulgar language of the Jews in our Saviour's time. They also very much serve the Christian cause against the Jews by interpreting many of the prophecies of the Messiah in the Old Testament, in the same manner as the Christians do. Many instances are produced to this purpose by Dr. Prideaux in his *Connect. of the Hist. of the Old and New Test.* vol. iv. p. 777, &c.

These Targums are published to the best advantage in the second edition of the great Hebrew bible set forth at Basil by Buxtorf the father, anno 1610, for he has rectified the Chaldee text, and reformed the vowel pointings in it: the Targums having at first been written without vowel points, which were afterwards added very erroneously by some Jews.

TARHONA, in *Geography*, a town of Africa, in Tripoli; 25 miles S.W. of Lebida.

TARI, or TORN, a river of Africa, which runs through the kingdom of Popo into the sea.

TARI, in *Commerce*. See TARO.

TARICHÆ, in *Ancient Geography*, islands situated on the coast of Africa, in the Mediterranean sea, between Leptis and Thapfus, mentioned by Strabo.

TARIDEGO, in *Geography*, a town of Africa, on the river St. Domingo. N. lat. $12^{\circ} 10'$. W. long. $13^{\circ} 56'$.

TARIENTO, a town of Italy, in Friuli; 8 miles N. of Udina.

TARIER of Buffon, in *Ornithology*. See MOTACILLA *Rubetra*.

TARIERA, in *Ichthyology*, the name of a river-fish caught in many parts of America.

It is an oblong fish, with a straight back, and a belly somewhat hanging down; its under jaw is longer than its upper, and its teeth are extremely sharp: among these are two longer than the rest in the middle of the under jaw, and four such in the upper; its scales are large, its back brown, and its belly and sides whitish. It is a well-tasted fish, but full of bones. Marcgrave.

TARIF, or TARIFF, *Book of Rates*; a table or catalogue, drawn usually in alphabetical order, containing the names of several kinds of merchandize, with the duties or customs to be paid for the same, as settled by authority, and agreed on between the several princes and states, that hold commerce together.

TARIFFA, in *Geography*, a sea-port town of Spain, in the province of Seville, situated on a bay to which it gives name, on the north side of the Straits of Gibraltar, fortified with old walls and towers, with a castle, in which the governor resides. By the Romans it was called "Julia Traducta," and "Julia Joza." The present name is from the Moors; 27 miles S.S.E. of Medina Sidonia. N. lat. $36^{\circ} 3'$. W. long. $5^{\circ} 41'$.

TARIFILON, in *Botany*, a name by which Avicenna, and some other authors, have called the *trifolium bituminosum*, or stinking trefoil.

TARIJA, in *Geography*, a jurisdiction of South Ame-

rica, in Peru, but placed under the viceroyalty of Buenos Ayres. This is represented a charming and fertile country, with a serene sky and a fine temperature of air, producing wheat, maize, and all other things that are essential to the support of man; together with the tree, which produces the herb of Paraguay, the cocoa, the vine, and flax, which is cultivated merely for the sake of its seed. In the abundance of pastures are fed a vast number of cattle and sheep. The annual transports of black cattle alone are computed at little less than 10,000 head, which are valued at from eight to ten piastres each. The hides tanned and prepared form sole-leather for the inhabitants of La Plata, Potosi, &c. The demands for Spanish and colonial merchandise annually exceed 60,000 piastres; the returns for which are made in productions of the province. St. Bernardo de Tarija is the chief town. Chicas and Tarija form one government.

TARIJA, a river of South America, which runs into the Vermejo, in the province of Tucuman.

TARIJA. See St. Bernardo de Tarija.

TARIN, in *Ornithology*, a name given by the French, and from them by many others, to the citrinella; a bird common in Italy, and kept in cages for its beauty and fine notes. See FRINGILLA.

TARINGASONG, in *Geography*, a town of Thibet; 17 miles S.S.E. of Lassa. N. lat. $28^{\circ} 6'$. E. long. 93° .

TARINGTING, in *Ornithology*, a name given by the people of the Philippine islands, to a species of lapwing, which is common on the sea-shores, and runs remarkably swift.

TARINURAK, in *Geography*, a river of Russia, which runs into the Lena, N. lat. 61° . E. long. $124^{\circ} 14'$.

TARISKERI, a town of the island of Metelin, on the N. coast; 12 miles E. of Cape Sigrì.

TARITH, one of the many names given by chemists to mercury.

TARITO, in *Geography*, a town of Thibet; 33 miles S.E. of Tchontori.

TARKA, a mountain of Transylvania; 28 miles N.N.E. of Udvarhely.

TARKI, a town of Hungary; 15 miles N.N.W. of Topoltzen.

TARKI, or *Tarku*, a town of Asia, in Daghestan, capital of the district of Schamgul, seated in N. lat. $42^{\circ} 50'$, and supposed to contain 10,000 inhabitants, stands on the Caspian shore, in a narrow glen, through which run many streams of salt-water.

TARKIRA-HOUTCHIN, a post of Chinese Tartary, in the country of the Monguls. N. lat. $44^{\circ} 34'$. E. long. $113^{\circ} 48'$.

TARKO, a town of Hungary, 6 miles E.S.E. of Szeben.

TARKSHA, a name of the fabulous bird Garuda, on which, in the mythology of the Hindoos, their god Vishnu rides. This vehicle, or vahan, in the Sanscrit tongue, is represented as half man half eagle; and offers an argument for the identity of the Hindoo deity, and the Jupiter of the Greeks. Another name of this bird is *Superna*; which see. See also VAHAN.

TARMA, in *Geography*, a jurisdiction of South America, in Peru, situated to the north of Atun Xauxa, about 90 miles from Lima, to which diocese it belongs, and is one of the most extensive in this part of Peru. The climate is temperate, and the soil fertile, except towards the mountains, where it is cold, and the land is chiefly applied to feeding of cattle; and many mines of silver are found. Tarma, the capital,

capital, is 85 miles E. of Lima. S. lat. 11°. W. long. 75° 50'.

TARMONBARRY BRIDGE, a village of the county of Roscommon, Ireland, at which there is a bridge over the Shannon. The royal canal, if it should ever be completed, is to join the Shannon near this place. It is 4 miles N.W. from Longford, and above 60 from Dublin.

TARMON-HILL, a mountain at the southern extremity of the peninsula, called *The Mullet*, being a detached part of the county of Mayo, Ireland.

TARN, a river of France, which rises in the mountains of Lozere, passes by Florac, Ispanhac, St. Enimie, Compeyre, Milhau, St. Rome, Alby, L'Isle, Rabastens, Ville-mur, Montauban, &c. and joins the Garonne, near Moissac, in the department of the Lot.

TARN, a department of France, being one of the nine departments of the southern region, and formerly a portion of Upper Languedoc, in N. lat. 43° 40', bounded on the N. and N.E. by the department of the Aveyron, on the S.E. by that of Hérault, on the S. by that of the Aude, and on the W. by the departments of the Upper Garonne and the Lot, and taking its name from the river Tarn, which traverses it from E. to W. Its territorial extent is 6080 kilometres, and its population comprehends 272,163 persons. It is divided into 4 circles, 35 cantons, and 356 communes. The circles are Gaillac, including 59,501 inhabitants; Alby, 63,064; Castres, 106,918; and Lavaur, 42,680 inhabitants. Its contributions in the 11th year of the French era, amounted to 2,693,820 francs; and its expences to 252,749 fr. 18 cents. According to Hassenfratz, its extent in French leagues is 30 in length, and 20 in breadth: it is divided into 5 circles and 48 cantons, and its population comprehends 289,148 souls. Its capital is Alby. This department is diversified with hills and plains, and abounds in a variety of productions, viz. grain, flax, hemp, wine, fruits, and pastures. It has considerable forests, with mines of iron, copper, lead, coal, quarries of marble, &c.

TARNA, a town of Sweden, in the lapmark of Umea: 145 miles N.W. of Umea.

TARNAC, a town of France, in the department of the Correze, on the Vienne; 25 miles N. of Tulle.

TARNAVAY, a town of Hindoostan, in the county of Calicut; 20 miles N.E. of Paniany.

TARNISHING, a diminution of the natural lustre of any thing, especially of a metal.

Gold and silver, when tarnished, resume their brightness, by setting them over the fire in certain leys. Copper, pewter, &c. that are tarnished, recover their lustre with tripoli and potashes.

TARNOGROD, in *Geography*, a town of Poland, in the palatinate of Belcz; 52 miles W.S.W. of Belcz.

TARNOPOL, a town of Austrian Poland, in Galicia; 72 miles E. of Lemberg. N. lat. 49° 30'. E. long. 25° 40'.

TARNOW, a town of Austrian Poland, in Galicia; 52 miles S.W. of Sandomir. N. lat. 49° 56'. E. long. 20° 53'.

TARNOWITZ, a town of Silesia, in the principality of Oppeln, near which is a silver mine; 6 miles N. of Ober Beuthen. N. lat. 50° 25'. E. long. 18° 47'.

TARO, a river which rises in the southern part of the duchy of Parma, and runs into the Po, 9 miles E. of Buffeto. The country through which it passes is called *Val di Taro*.—Also, a late department of France, formed by the duchies of Placentia and Parma.

TARO, in *Commerce*, a money of account and copper coin of Naples, Sicily, and Malta. For the accounts at Malta, see *Scudo*. The banks at Naples keep their accounts in ducati, tari, and grani. A ducat contains 5 tari, 10 carlini, or

40 cinquini: a taro, or tarino, is worth 2 carlini, or 20 grani. Among the silver coins are tari, at 2 carlini. By the coinage of 1804, the piece of 12 carlini should contain 350½ English grains of fine silver; so that it is worth 49d. sterling; and the ducat of 10 carlini is worth 41d. sterling nearly, or 1l. sterling = 5 ducats 88 grani. The taro of Sicily is worth about 4d., or more accurately, 1l. sterling = 1 ounce 28 tari 15 grani.

TAROATAIHETOOMO, is the name of one of the two first or supreme deities at Otaheite: the other, who is supposed to have been a rock, is called *Tepapa*. These produced a son called *Tane*, to whom their prayers are generally addressed, and who is supposed to interest himself in the affairs of mankind; and a daughter called *Tellowmatatayo*, the *Year*, from whom proceed the months and days. From the two first beings they suppose also to have sprung an inferior race of deities called *Eatus*. Hawkefworth's *Voy.* vol. ii. p. 238.

TARODUNUM, in *Ancient Geography*, a town of Germany, near the Danube, and in the vicinity of Arae Flavix.

TAROM, in *Geography*. See **TARUM**.

TARON, or **TIROAN**, a town of Persia, in the province of Adirbeitzan; 120 miles S.E. of Tauris.

TARONA, in *Ancient Geography*, a town of the Tauric Chersonesus, S.E. of Taphra, and E. of Satarcha.

TARONCHI, in *Geography*, a town of Hindoostan, in Mysore; 15 miles S.S.W. of Chinna Balabaram.

TAROUC YAMDSO, a lake of Thibet, about 53 miles in circumference. N. lat. 31° 52'. E. long. 84° 38'.

TAROUCA, a town of Portugal, in the province of Beira; 9 miles S. of Lamego.

TAROULA, a town on the east coast of the island of Tidor. N. lat. 0° 42'. E. long. 127° 20'.

TAROURS, a town of Hindoostan, in Berar; 30 miles N.N.E. of Neermul.

TAROUT, a town of Arabia, in the province of Hedsjas; 32 miles S.E. of El Catif.

TARP, a town of Sweden, in the province of Dalland; 12 miles N. of Uddevalla.

TARPANS, a kind of wild horses in the Caucasian desert, E. of the river Yaik. They are of a middling size, roundish, short, generally of a blueish-grey colour, with big heads, and ewe-necked. They are taken with a noose, and broken to the saddle by being coupled to a tame horse.

TARPAULIN, or **TARPAWLING**, is a piece of canvas, well pitched and tarred over, to cover the hatchways of a ship at sea, in order to prevent the penetration of the rain or sea-water, which may occasionally rush over the decks.

The term is also used in derision for a person bred at sea, and educated in the mariner's art. We also, of late, use it to express a painted floor-cloth.

TARPAULIN Cove, in *Geography*, a bay on the S. of Massachusetts, near Falmouth.

TARPEIAN, **TARPEIUS**, in *Antiquity*, an epithet given to a rock in ancient Rome, of considerable height; whence, by the law of the Twelve Tables, those guilty of certain crimes were precipitated. It was on this rock that the Capitol was built.

The Tarpeian rock might formerly be steep enough on one side to break a man's neck; but it could never have been of that surprising height mentioned by some writers, if any judgment can be formed from its appearance at present. See Burnet's *Letters*, p. 238, and Miffon's *N. Voyage*, p. 103.

It took its name from a vestal, called *Tarpeia*, who betrayed the Capitol, of which her father was governor, to the Sabines; on condition that they would give her all they bore

bore on their left arms, meaning their bracelets. But, instead of bracelets, they threw their bucklers (which were likewise borne on their left arm) upon her head, and crushed her to death.

Others ascribe the delivery of the Capitol to her father, Spurius Tarpeius; and add, that he was precipitated down this rock by Romulus's order, and that this henceforward became the punishment of all criminals of the like kind.

TARPEIAN Games, Ludi Tarpeii, were games instituted by Romulus in honour of Jupiter Feretrius; and called also *Capitolini ludi*. See *CAPITOLINE*.

TARPORLEY, in *Geography*, a small market-town in the hundred of Edisbury, and county palatine of Chester, England, is situated on the great road from London to Chester, at the distance of 172 miles N.W. from the former, and 11 miles E.S.E. from the latter. In ancient records, Tarporely is called a borough, and the houses burgages: it had in former times a mayor, as appears by deeds of the years 1348 and 1396: it is now governed by a constable. The market, which was originally on Tuesday, was granted in 1281 to Hugh de Tarporely, then lord of the manor: it had been many years disused, but was restored in 1705 by Sir John Crew, who also procured a grant of three annual fairs, and built a market-house. The parish of Tarporely, which includes the townships of Eaton, Rushton, and Utkinton, contained in the year 1811, according to the population report, 365 houses, and 1852 inhabitants. An annual fox-hunt, of great celebrity, is held at Tarporely, on the first week in November, during which week are horse-races, at a place called Crab-tree Green, on Delamere forest.

About two miles southward of Tarporely rises the great insulated rock of Beeston. It is composed of sand-stone, and is nearly perpendicular on one side, which gives it a tremendous appearance, but the other side gradually slopes to the level of the country. Its height is 366 feet. On the crest of this rock are the stately ruins of the far-famed Beeston castle, whose almost impregnable strength was once proverbial. This fortress was erected in 1220 by Ranulph de Blundeville, earl of Chester. It consisted of an outer and inner area. The outer was defended by a strong wall, fortified with round towers, which ran across the slope from one end of the precipice to the other. Some parts of this wall, and six of the towers, are still extant. The area inclosed is nearly five acres. The castle was defended, on one side of the area, by a deep ditch cut out of the solid rock; on the other, by the abrupt precipice that overhangs the vale of Cheshire. The entrance is through a noble gateway, guarded on each side by a great round tower, with walls of prodigious thickness. During the civil wars of the 17th century, this fortress was alternately besieged by the royal and parliamentary forces; and in 1646 was dismantled by order of the parliament.—Lysons's *Magna Britannia*, vol. ii. part 2. Cheshire. Beauties of England and Wales, vol. ii. Cheshire, by J. Britton and E. W. Brayley.

TARPOU, a lake of Thibet, about 60 miles in circumference. N. lat. 30° 32'. W. long. 81° 54'.

TARQUINIUS PRISCUS, *Tarquin the Ancient*, in *Biography*, the fifth king of Rome, was the son of an opulent merchant of Corinth, who, escaping from tyranny at home, settled at Tarquinii, in Etruria, where he married a female of rank, by whom he had two sons. One of them died, and the other, named Lucumo, was urged by his wife Tanaquil, a lady of rank and of ambition, to remove from Etruria to Rome; where he changed his prænomen Lucumo into Lucius, and his family name Damaratus into Tarquinius, borrowed from his native city. Here he ingratiated him-

self by his manners with Ancus Martius, the king, and also with the people; and by the liberal application of his wealth to public purposes, particularly to the support of the wars in which Rome was engaged, as well as by his skill and valour in the field, he gained a reputation which served to advance him to the rank of patrician and senator. Ancus also appointed him to the confidential office of guardian to his two sons. Upon the death of Ancus, B. C. 616, the ambition of Tarquin prompted him to take measures for securing the succession to himself. The crown being elective, he contrived, by bribes and solicitations, to obtain the suffrages of the people, who proclaimed him king; and in order to strengthen his interest in the senate, he introduced from plebeian families 200 new members into this body. In his wars with the Latins, he took several of their towns, and obliged the Sabines and Etrurians, whose confederacy he defeated, to seek an alliance with Rome on humiliating terms. Tarquin, in honour of his success, was granted a triumph; and the spoils of war were devoted to the erection of the Circus Maximus, for the exhibition of the Roman or great games. The Etrurians, having afterwards rebelled, obtained peace upon condition of their recognizing Tarquin as their sovereign. During an interval of peace, after a nine years' war, Tarquin employed himself in improving the city, by enclosing it with walls, and by constructing those sewers, which were in subsequent times the objects of admiration. On occasion of a new war with the Sabines, Tarquin, whose army was deficient in cavalry, augmented the strength of each division; and having defeated the Sabines, they submitted, and surrendered all their fortresses to the Romans. At this time Tarquin fulfilled his vow of erecting a temple to Jupiter, Juno, and Minerva, on the Tarpeian rock; and by this act he acquired the honour of founding the principal seat of the Roman worship. Having attained to his 80th year, the sons of Ancus took occasion to make an attempt for defeating his plan of continuing the crown in his own family by the marriage of his daughter to Servius Tullius, by conspiring against his life. They so far succeeded as to procure the assassination of the king. His queen Tanaquil, however, by keeping the event secret, adopted measures for securing the succession of her son-in-law: and the sons of Ancus, whose plot had been detected, went into voluntary banishment. Thus ended, in the year B. C. 570, the prosperous and splendid reign of Tarquin the elder, one of the most illustrious of the Roman kings, and equally distinguished by his conduct in peace and in war. Univ. Hist.

TARQUINIUS SUPERBUS, or *Tarquin the Proud*, supposed to have been a grandson of the elder Tarquin, ascended the throne in the year B. C. 534. His government was arbitrary and tyrannical, and it was supported by a band of foreign mercenaries, employed in the defence of himself and his party, who had contributed to advance him to the throne in contempt of the suffrages of the people. Many of the principal senators dreading the fate of those who were made the victims of his suspicion and avarice, retired into a voluntary exile. The plebeians, at first pleased with the humiliation of the senate, had some reason to complain of the yoke imposed upon themselves. The laws that had been made in their favour were abrogated; spies and informers watched their words and actions; and all public assemblies for business or amusement were prohibited. Tarquin, conscious of the odium of the Roman citizens, took measures for ingratiating himself with the allies; and with this view, he erected a temple near the ruins of Alba, consecrated to Jupiter Latiaris, at which the diets of the confederate cantons were annually to assemble; the Romans,

as chief members of the confederation, presiding at the sacrifices and deliberations. This institution contributed to the strength of the Roman state, and the extension of its dominion throughout Italy. Having taken up arms against the Volscians and Sabines, he returned, after a successful war, to Rome, and twice triumphed; and he took occasion to finish the great circus and the sewers, which his grandfather had begun. But a war again commenced with some discontented patricians, who had taken refuge at Gabii, a Latin city not far from Rome; and this war lasted seven years. At length Gabii was conquered by the treachery of Sextus, one of Tarquin's sons; and the inhabitants, whom he treated with lenity, were incorporated with the Romans. During the reign of this Tarquin, the Sibylline books were brought to Rome, as we have related under that article, and the Capitoline temple finished. Ardea, the capital of the Rutuli, was the next object of Tarquin's military enterprise; and this circumstance was the remote cause of the rape of Lucretia by Sextus Tarquin, which at length occasioned the expulsion of the Tarquinian family from Rome, as well as the extinction of the kingly government. Brutus, availing himself of the passions excited among the multitude by the tragic fate of Lucretia, and exposing the tyrannical government under which Rome groaned, obtained a public decree for the banishment of Tarquin and his sons, and the army concurring in this resolution, the king was reduced to the necessity, at the age of 76, B. C. 509, to abandon his capital, and take refuge at Cere, in Etruria. Many attempts were made for his restoration, but all proved ineffectual. Tarquin retired into Campania, and died there, in the 90th year of his age, and 14th of his exile. Possessing talents fit for command, he was nevertheless violent, cruel, and wholly unprincipled. Univ. Hist. Gen. Biog.

TARRA, in *Ancient Geography*, a town of Asia Minor, in Lydia.—Also, a town and mountain of Crete.

TARRABERRY, in *Geography*, a town of Bengal; 30 miles N. of Dinagepour.

TARRABOGA, a town of Bengal; 45 miles S. of Doefa.

TARRACE, **TARRASS**, *Terrace*, or *Terrass*, a coarse sort of plaster, or mortar, durable in the wet, and chiefly used to line basins, cisterns, wells, and other reservoirs of water. See *Calcareous CEMENT*.

That which is called the Dutch terrass, is made of a soft rock-stone, found near Collen, upon the lower part of the Rhine; it is burnt like lime, and afterwards reduced to powder by means of mills: from thence it is brought to Holland in great quantities, where it has acquired the name of Dutch terrass. It is of a greyish colour when it is not mixt, which is very seldom the case: because it is very dear, and the demand for it in aquatic works very great. It is said that in some parts of England there is found a soft stone, resembling that of Dutch terrass, and which might serve as well in aquatic works.

An artificial terrass, resembling the true, may be formed of two parts of lime, and one of plaster of Paris, well beaten together, and used immediately. There is another sort of terrass, used for coarser uses, which is sometimes called *Wellb* terrass, formed of one part lime, and two parts of well-sifted coal-ashes, thoroughly mixt by being well beaten together. Handm. to the Arts, vol. ii. p. 32.

TARRACO, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Cofetani. This was an ancient town in the time of the Romans. Some Spanish authors have attributed its foundation to Tubal. Others, with greater probability, ascribe it to the Phœnicians, who called it Tarcon, which the Romans changed into Tarraco. Having

been destroyed, it was re-established by the two Scipios. At length it became the capital of that region, to which it gave the name of Hispania Tarragonensis. Augustus visited this city on occasion of his war against the Cantabri; and it was here that the first altar was erected to his honour. Galba, A. D. 68, was presented by the Tarraconians with a crown of gold. It was in the year 121 or 122 that Adrian re-established the temple built in this city in honour of Augustus, under the reign of Tiberius. See **TARRAGONA**.

TARRAGON, in *Botany*, a name sometimes given to *southernwood*; which see. See also **ARTEMISIA**.

TARRAGONA, in *Geography*, a town of Spain, in the province of Catalonia, situated on a rising ground on the coast of the Mediterranean, at the mouth of the river Francoli, and one of the most ancient cities in Spain, said to have been founded by the Phœnicians. Under the Romans it was the capital of a province, called Tarragonensis, and was fortified by Scipio as a defence against the Carthaginians. In the year 467 it was taken by the Goths, and levelled with the ground. In 516, a council was held here, in which monks are first mentioned; when it was ordained that the sabbath should commence on Saturday evening. It afterwards fell into the hands of the Moors, from whom it was recovered in the latter part of the 11th century, and rebuilt by the archbishop of Toledo, who was by the pope absolved of the oath he had taken of going to the holy war, on condition that he would lay out the sum designed for that expedition in rebuilding Tarragona. In the war of the succession, the English obtained possession of this city, and intended to keep and fortify it, by bringing the river Francoli quite round it; and for this purpose threw up vast out-works and redoubts, the ruins of which are yet visible. On the possession of Gibraltar, they gave up the design. The environs at Campus Tarragonensis they esteem one of the most fertile spots in Europe. Tarragona has but few remains of its ancient grandeur; inscriptions almost destroyed by time, some coins, and a few ruins, give but an imperfect idea of what it formerly was. It is now depopulated, and of little importance. The harbour is dangerous, and not much frequented; there are a few bastions in bad repair, which were formerly built for its defence. Tarragona is, however, the see of an archbishop, the metropolis of Catalonia, and disputes with Toledo the primacy of Spain. The establishment of the see is said to have been in the first ages of the church: the succession of archbishops was interrupted by the Moors, and remained suspended until the 11th century. The cathedral is worthy of attention for its vast dimensions, the elegance of its Gothic architecture, and a magnificent chapel, built with rich marble and jasper, in honour of St. Thecla, tutelar saint of the church; 98 miles E. S. E. of Saragossa. N. lat. 41° 8'. E. long. 1° 33'.

TARRAGUNGE, a town of Bengal; 22 miles S. E. of Moorshedabad.

TARRAPOUR, a town of Hindoostan, in Bengal; 17 miles S. W. of Boglipour.—Also, a town of Hindoostan, in Malwa, on the Nerbuddah; 12 miles S. of Mundu.

TARRAR, a circle of Hindoostan, in Allahabad, bounded on the north by Allahabad Proper, on the E. by Chunar, on the south-east by Boggilcund, and on the west by Bundeleund; about 35 miles long, and 12 broad.

TARRASA, a town of Spain, in Catalonia; 13 miles N. of Barcelona.

TARRATZ POINT, a cape on the north coast of St. Vincent. N. lat. 13° 24'. W. long. 65° 15'.

TARREGA, a town of Spain, in Catalonia, on the Cervera;

Cervera; 5 miles W. of Cervera. N. lat. $41^{\circ} 36'$. E. long. $0^{\circ} 19'$.

TARRIE, in *Commerce*, a measure at Algiers for corn and dry goods, holding somewhat less than $2\frac{1}{4}$ pecks English measure; 16 tarries make a caffle.

TARROCK, in *Ornithology*, the name of a sea-fowl of the larus or gull-kind, and distinguished by authors by the name of the *larus cinereus Bellonii*; and called by Linnæus the *LARUS tridactylus*; which see.

It is of the size of the common pigeon, and is not much unlike it in shape, except that the head is larger and thicker. The bill is black, short, thick, and strong; the throat, neck, and under side are white; near each ear, and under the throat, is a black spot; on the hind part of the neck is a black crescent, with the horns pointing to the throat.

Its great distinction, however, from all the other birds of the gull-kind, is, that it has no hinder toe, but in lieu of it a small protuberance. It is very common on the coasts of Cornwall, and some other of the English shores. Ray and Pennant.

TARRY-TOWN, in *Geography*, a town of New York, where major André, of the British army, was apprehended as a spy; 24 miles N. of New York.

TARSAH, a town of Hindoostan, in Berar; 18 miles E. of Nagpour.

TARSI, in the *Materia Medica*, a name by which some authors have called the root of the *cyperus esculentus*, or sweet cyperus of the shops, and by which it is, in some places, usually called by the druggists. See AVELLANDA and HABHAZZIS.

TARSO, in the *Glass Trade*, a sort of white stone found in many rivers in Italy, and other places; and used instead of sand for the finest crystal-glass, being first burnt, and calcined with the salt of the pulverine into frit. Neri's Art of Glass, p. 7.

Neri calls this stone a kind of white marble; and adds a general rule, that all stones that will strike fire with steel, are fit to vitrify; and those that will not strike fire with steel, will never vitrify.

The criteria or determinate characters of fossils were not at all fixed in this author's time, otherwise he had not called this stone a kind of marble; since his own general rule of trying stones by steel is, though liable to a few exceptions, a very good one; and, according to that, this tarso could be of no affinity to marble; for marble will not strike fire with steel, nor ever be converted into glass.

The tarso, therefore, of this and other authors, could be nothing of the marble kind; but is truly a crystalline matter debased by an admixture of white earth, and found in form of small pebbles, of a whitish, yellowish, or pale reddish colour; and this is common in all the gravel-pits of England, and in the beds of some of our rivers; and might be used with great advantage by our glass-makers, if they knew it was so easily to be had.

On comparing these stones of ours, with the cuogoli, or tarso of the foreign glass-makers, there is no difference distinguishable to the eye, nor will the nicest experiments by the fire, acid menstrua, &c. shew the least distinction between them. We are not to wonder, however, that the glass-makers did not hitherto distinguish this to be the true cuogoli, or tarso, since the characters of fossils have been hitherto so little ascertained, that the best and latest author on these subjects, Dr. Woodward, so far mistook the structure of this stone, as to call it a sparry pebble. It is certain that spar could never have any thing to do with glass-making; but this stone has no spar in its composition.

TARSUS, in *Ancient Geography*, a town and country of Asia, in Bithynia. Steph. Byz.

TARSUS, in *Geography*, a sea-port town of Asiatic Turkey, in the government of Marasch, said to have been founded by Sardanapalus. It was at one time the capital of Cilicia, and traversed by the river Cydnus. It is mentioned by Dionysius Periegetes, Ptolemy, Mela, Pliny, and Strabo, the latter of whom says, that it was very powerful and populous; that its inhabitants excelled in the study of philosophy, and of all the sciences cultivated among the Greeks; indeed in this respect they surpassed Athens, Alexandria, and all other academies in the world. It is now inhabited by Turks, Greeks, and Armenians, and is the see of a Jacobite bishop and Nestorian archbishop. It is large, and surrounded with a double wall. St. Paul called himself a native of Tarsus; and here the emperor Julian was buried. It has been said that in the time of St. Paul, Tarsus was a Roman colony, and that the apostle was a citizen of Rome by virtue of his nativity at Tarsus. (Acts, xxi. 37—39. ch. xxii. 3.) But Dr. Lardner has particularly examined this point, and alleged several arguments to prove, that Tarsus, though it was no mean city, as St. Luke says, was not a municipium, or town of Roman citizens. (See ST. PAUL.) Tarsus was taken by the Saracens in 640; 25 miles W. of Adana. N. lat. $37^{\circ} 1'$. E. long. $34^{\circ} 37'$.

TARSUS, in *Anatomy*, that part of the foot (consisting of about its posterior half) to which the leg is articulated. Its front portion corresponds to the instep in common language. See EXTREMITIES.

The same name is applied to the portion of cartilage contained in each eyelid. See EYE.

TARTAGLIA, NICHOLAS, in *Biography*, a celebrated mathematician, was born at Brescia about the beginning of the 16th century. Being left destitute in his childhood by the death of his father, he was no less unfortunate at the siege of Brescia in 1512, in receiving several wounds, and particularly one which divided his lip, so that he lost the power of distinct articulation; and from this circumstance he got the name of Tartaglia. The defects of his early education were amply compensated by his genius and diligence. Having resided ten years at Verona, he afterwards, viz. in 1534, became professor of the mathematics at Venice; and here, except during an interval of eighteen months at Brescia, he remained till the time of his death, in 1557. His works are numerous. Besides translations of Archimedes and Euclid, he wrote many original treatises in mathematics, one of the most important of which, entitled "Questi e' inventione diversi," was published at Venice in 1546, and dedicated to Henry VIII. of England. It is comprehended in nine books, and contains answers to several questions that were proposed to him at different times concerning mechanics, hydrostatics, &c.; and more particularly worthy of notice is the history of the invention of the rules for solving cubic equations, which he communicated to Cardan, under an oath that he would keep the secret. (See ALGEBRA and CARDAN.) Tartaglia's genius was no less conspicuously displayed in other sciences than in algebra. He treats of artillery and gunnery, and also of the different methods of fortifying towns, besides various mechanical and algebraical questions. He also proposes many questions with regard to the motion of bodies, and the method of measuring distances, in his "Nuovia Scienza" and "De' Numeri e Misure." To Tartaglia we owe the first discovery of the best angle, i. e. 45° , as it was then thought, for elevating a piece so as to throw a ball or shell to the greatest distance. He also announced a method of raising vessels that were

sunk, and other heavy bodies, from the bottom of the sea, and the means by which a person may be enabled to remain a considerable time under water; and to him we owe a treatise on the signs which indicate changes in the atmosphere. He has likewise furnished us with a large treatise on arithmetic, algebra, and geometry, published at Venice, in folio, in 1556. Tiraboschi remarks, that all Tartaglia's works manifest great penetration and acuteness, and that they would claim higher commendation, if the author had paid more attention to his style, and if the editions were more correctly printed. But with all their imperfections and faults, and after all the improvements to which they have led the way, they were justly esteemed at the time when they were written, and they have been useful to those who have in more modern times pursued the same course of study and investigation. Tiraboschi. Montucla. Hutton.

Tartaglia is mentioned by Pietro della Valle among great Roman musicians in 1640, and the composer of "Clearco," the first opera that was performed at a public theatre in Rome. For though several musical dramas had been exhibited in the palaces of ambassadors and other great personages in that city, no theatre had been previously opened there for the public at large.

TARTAGLINI, LA ROSA, the daughter of Tibaldi, an excellent tenor singer in the service of the emperor at Vienna. She was extremely celebrated for her beauty and agility of voice, and quitted the stage in 1768.

TARTALA, in *Geography*, a town of Hindoostan, in Calicut; 21 miles E. of Paniany.

TARTAN, in *Sea Language*, a small coasting vessel navigated in the Mediterranean sea, and having only one mast and a bowsprit, the principal sail, which is extremely large, being extended by a lateen-yard.

When tartans put up a square sail, it is called a *sail of fortune*.

TARTAR, TARTARUS, or *Tartarum*, in *Chemistry*, an acid concrete salt which rises from wines, after complete fermentation, and sticking to the top and sides of the casks, forms a crust, which hardens to the consistence of a stone. It is in this state a hard, brittle, brown-red mass, interspersed with imperfectly crystallized particles; and called *crude* or *rough tartar*, or *argol*, by way of distinction from that which is purified.

Its goodness rather depends on the number of repeated fermentations, which a succession of new wines in the same casks for several years makes, than on the soil or climate where the wine is produced.

The sweet wines afford always less tartar than the sharp ones, and it is also less valuable. The tartar of Rhenish wine is better than that of any other; and in general those wines which have the most acid in them, and which are the most coloured and strongest-bodied, afford the greatest quantity of tartar, and that in the largest crystals.

The taste of tartar is vinous, and slightly acid. It is not entirely a product of fermentation, for it is contained in the "must," or grape juice, and assists in the process of fermentation, and the production of alcohol. This salt has also been found native, under different combinations, in some other vegetable juices.

Besides the usual way in which tartar is produced, there is a very remarkable account in the Memoirs of the Academy of Sciences at Paris, an. 1737, of its having been found in a more than ordinary beautiful state on a human skull: the discovery was owing to accident, and it was found that there had been lees of wine in the vessel in which the skull had been laid ten days in soak.

The formation of the crystals of this tartar on the skull, while the sides of the vessel had none created on them, shews that the skull had a disposition for receiving the crystals more than any other body; and their peculiar brightness proves, that it had some share in their formation.

Tartar consists of a large quantity of extractive matter, scarcely soluble in water, to which it owes its colour, and of a salt, quite white when pure, composed of acid of tartar united to a small portion of potash, less than is required for the saturation of the acid, but which, in this proportion, forms a distinct crystallizable salt of considerable importance in several arts and manufactures.

Tartar is either *white*, or *red*, according to the colour of the wine from which it is produced. That brought from Germany is the best, as being taken out of those monstrous tuns, some of which hold a thousand pipes of wine, so that the salt has time to come to its consistence, which is one of the chief qualities to be regarded in tartar. That of Montpellier is the next in order; then that of Lyons, Paris, &c.

White tartar is preferred to red, and is really better, as containing less of the drossy or earthy part; though both kinds, when purified, are exactly the same. The marks of good tartar of either kind are, its being thick, brittle, brilliant, and but little earthy.

Tartar, in its *crude* state, is much used as a flux in the assaying of ores. As it contains both alkali and carbonaceous matter, it acts both in assisting the fusion of refractory ores, and in reducing metallic salts and oxyds. When heated *per se* to redness in close vessels, the extractive matter and the tartareous acid both become charred, and the result is a black alkaline carbonaceous mass. In open vessels the charcoal burns off totally, and at last nothing remains but pure white carbonate of potash. But tartar is for the most part refined, in order to obtain the pure salt; which is called *purified tartar*, *cream of tartar*, *crystals of tartar*; or more accurately, according to the modern nomenclature, *acidulous tartrate of potash*, or *super-tartrate of potash*, and sometimes with less precision, simply *tartar*. This salt is purified in large quantities at Venice, and in France near Montpellier, by two different processes, which have been described by Desmaret (*Journ. Phys.* tom. i. p. 67.) and by M. Fizes (*Mem. de l'Acad.* for 1725), and which we shall here extract from Aikin's dictionary. At Venice the method is as follows: "The crude tartar is first dried in an iron boiler, with a very gentle heat and frequent stirring, that the acid may not be burnt, and is then pounded in iron mortars. The ground tartar is then distributed into wooden tubs, and boiling water poured upon it, which dissolves the salt, and leaves a sediment, which is thrown away. The clear solution is left three days at rest, during which time it deposits brownish crystals of tartar. The mother-liquor from this operation is reserved, and is used hot in the subsequent processes in the first lixiviation of the tartar. The brownish crystals of tartar are then put into a copper boiler, with the mother-liquor of former processes, and slowly brought to boil, by which a saturated solution of a deep yellow wine-colour is produced. This is clarified in the following way: a workman stands by the side of the copper with a basket of eggs, and a bucket full of finely sifted wood-ashes. He begins with breaking one of the eggs, and putting the white of it only into a bowl; he beats this up with some of the boiling liquor, and then pours the whole into the boiler: he then instantly throws in a ladleful of the wood-ashes, and stirs up the liquor from the bottom. A brisk effervescence takes place, and the surface is covered with a red scum, which is carefully taken off with a perforated skimming-dish,

and

TARTAR.

and put aside: a second portion of ashes is then added, and the effervescence and scum are renewed and treated as before. The whole of this operation is repeated fourteen or fifteen times, after which the liquor becomes quite clear and colourless. The fire is then withdrawn, and the liquor suffered to remain perfectly at rest for three days. On the fourth, a dirty white saline crust is removed from the surface, and two-thirds of the liquor laded out: the crystals on the sides are then collected by a ladle, and washed in the remaining liquor; they are thus obtained perfectly clean, and require no further preparation than drying on a wicker frame. The crystals from the bottom are still somewhat coloured, and are either sold as an inferior sort, or are refined again with fresh portions of the crude tartar. The liquor that remains in the boiler, after the deposition of the crystals, is a cold saturated solution of tartar, and is employed in the first lixiviation of the rough tartar."

The method used near Montpellier has been found so convenient and effectual, that it has continued without any material alteration for a century. It is as follows: "The apparatus required for this purpose is, 1st, a large copper boiler; 2d, a stone cistern, larger than the boiler; 3d, a number of glazed earthen pots (generally twenty-seven), which, together, hold somewhat more than the boiler; 4th, some strainers of coarse cloth stretched on wooden frames; 5th, four smaller copper boilers, which, together, hold as much as the larger boiler, and are used in the refining part of the process; and 6th, a mill to grind the tartar.

"The large copper is first filled with two-thirds of mother-liquor, remaining from the previous operations, and one-third of spring-water; a quantity of rough tartar is then thrown in, and, when the liquor is saturated and boiling, it is strained into the earthen pots. In about half an hour the liquor in these pots, though still very hot, begins to deposit crystals on the surface and sides of the pot; during which time, more liquor and tartar are thrown into the large copper, as at first.

"The liquor in the pots is then emptied into the stone cistern, leaving the crystallized crust of tartar behind; and when the second boiling is saturated, the pots are again filled as before, and the large copper again charged with the clear liquor from the cistern, and fresh tartar. By thus five times alternately preparing a hot saturated solution, and allowing it partially to deposit its tartar in the pots, the latter become lined to a considerable thickness with a crust of reddish-white tartar, much purer than at first, and which obviously consists of an irregular crystallized saline mass, and when washed with cold water, is fit for the second or proper refining process. For this purpose the four small boilers are filled with water, in which a small quantity of clay is diffused, which renders it milky, rejecting the stony and larger particles of earth. The half-purified tartar is then added in such proportion, that the water, when boiling, shall be sufficient to dissolve all the soluble part, and the ebullition is continued for a quarter of an hour; the fire is then withdrawn, and the liquor allowed to remain at rest till the next day. It is then found covered on the surface with a white hard saline crust, and a similar crust, but more distinctly crystallized, has concreted on the sides and bottom of the boiler. They are both very pure tartar, the crust on the surface, which is an amorphous mass, is called *cream of tartar*; and the other, *crystals of tartar*; but they are indiscriminately mixed.

"The crust is then broken down, and falls to the bottom; and the liquor, which is a clear pale red, is poured off gently into the stone cistern, till it begins to run white, owing to the clay at bottom, which latter portion passes into a separate vessel. The whole mass of solid tartar left in the boiler

is then washed with cold water, till all the foulness (which is merely superficial) is got out, and the water comes away quite clear; after which the purified tartar is taken out, and dried on stoves or in the sun, and is perfectly pure and white. The ordinary rough tartar yields about three-fifths of its weight of the white pure salt. All the residuary liquors are employed in subsequent operations; in the way already mentioned."

Schaub says (Annal. de Chim. xlix. 61.), that tartar may be purified by simply boiling it with powdered recent charcoal, and thus very white crystals are obtained.

TARTAR, *Burnt*, a preparation used by glass-manufacturers, and consisting of large lumps of red tartar, burnt or calcined in earthen pans in an open fire, till they have done fuming: it is of a blackish purple colour. Neri's Art of Glass.

TARTAR, *Cream of*, *Cremor Tartari*. See CREAM of Tartar, TARTAR, *supra*, *Super-tartrate of Potash*, under SALTS, and TARTRITES.

Cream of tartar has a sensibly acid taste; it reddens the blue colours of vegetables; it may be saturated by uniting with any of those substances, which are capable of forming with acids neutral salts; and it may be afterwards separated from those substances, and recover its former appearance.

In the arts, and in the materia medica, this is a very valuable salt. It is much used in dyeing, more especially in giving the scarlet and other modifications of the cochineal colours. It is also often combined with alum, as a mordant in fixing colours. (See DYEING.) As an article of the materia medica, cream of tartar, dissolved in water, forms an agreeable and cheap acidulous drink; and as a sweetener of the blood, some have taken it in whey or water-gruel, in the spring-time, to the quantity of half an ounce every morning, for three or four weeks. The solution in water, sweetened with sugar, is a pleasant beverage in febrile diseases, when its purgative quality is not likely to prove injurious. See the next article.

The difficult solubility of cream of tartar being an objection to its medical use, some experiments were made by Dr. Peter Jonas Berg, for rendering it more soluble by certain additions, without altering its medicinal qualities. Borax was found to answer best for this purpose. To four parts of cream of tartar one of borax was added. These were dissolved in a sufficient quantity of water, and the liquor strained: about a sixteenth part of impurities was left behind. The pure solution evaporated yielded an acid, and extremely soluble white salt. Lemery has also recommended borax. It has, however, been observed, that as borax contains an excess of alkali, the acid of the tartar would be neutralized, and a very different salt would be produced, *viz.* the *tartrate of potash and soda*; which see. Nova Act. Phys. Med. Acad. Cæs. Leop. Carol. Nat. Curios. tom. iv.

TARTAR, *Crystals of*. See TARTAR, *supra*, and TARTRITES.

These crystals are small and irregular, but generally run together into little masses of a white colour, semi-transparent, brittle, and easily reduced into powder. Crystals of tartar are in common use as a laxative and mild cathartic; they are also esteemed for their cooling and diuretic qualities, and have therefore been much employed in dropries, and in other cases requiring an antiphlogistic treatment. Dr. Cullen says, that in large doses they act like a purgative, in exciting the action of the absorbents in every part of the system, and more powerfully than the operation of any entirely neutral salts. On this property is founded their utility in the case of dropfy. They occasion a considerable discharge of serous fluid into the bowels, which is thrown off

in the form of ferous stools; the discharge by urine being also augmented. The water in the cavity of the abdomen is thus rapidly carried off; and the chances of a return of the disease are supposed to be fewer than when other diuretics are employed. It is remarked, that they do not readily pass off by the kidneys, unless they are taken with a large quantity of water; and, therefore, when intended as a diuretic, they ought to be given in a liquid form, as Dr. Holme has directed. It has been suggested, that, in cases complicated with hepatic obstructions, the effects of this remedy are very uncertain. It may be advantageously united with squills; and, on account of the exhaustion which it occasions, the use of it should be followed by preparations of iron, and other tonics. As a purgative and hydragogue, the dose is from $\mathfrak{z}iv$ to $\mathfrak{z}vj$, in the form of electuary; and for the latter purpose, this dose must be repeated until the kidneys are affected; diluting freely during its use. These salts enter several official compositions: such as "carbonas potassæ purissimus," Ed. Ph.; "ferrum tartarizatum," L. D.; "pulvis jalapæ compositus," E.; "pulvis scammonii compositus," E.; "pulvis fennæ compositus," E.; "potassæ tartaræ," L. E. D.; "antimonium tartarizatum," L. E. D.; "foda tartarizata," L. E. D. Woodville. T. Thomson.

TARTAR, *Emetic*. See ANTIMONY.

A considerable diversity has occurred in the method of preparing this tartar, probably from want of considering, that the emetic quality of this preparation proceeds from the metallic earth being dissolved by the acid of tartar, and forming with it a kind of soluble tartar, a true neutral salt, no less capable of a very exact solution than the vegetable salt, the salt of feignette, and all the other soluble tartars. By considering this saturation as a fixed point, there may be produced only one kind of emetic tartar, always equally strong. See a detail of M. Geoffroy's experiments on this subject, in Mem. Acad. Par. for 1734. M. Beaumé directs it to be prepared by mixing together equal parts of cream of tartar, and of porphyrised glass of antimony, or rather a larger quantity of the latter ingredient. This mixture is to be thrown gradually into boiling water; and the boiling must be continued gently, till there is no effervescence, and till the cream of tartar be entirely saturated. The liquor is to be filtrated; and when it is cooled, there will be formed in it fine crystals, in the form of pyramids with triangular bases, which are a soluble tartar perfectly saturated with glass of antimony. These are transparent while moist; but by exposure to a dry air, they lose a part of the water of their crystallization, and become opaque and white. Emetic tartar thus prepared, very well produces an emetic effect when taken from a grain to two and a half, or three, according to the constitution of the patient. The result of M. Beaumé's experiments on the manner and duration of boiling this preparation is, that vessels of iron and copper ought to be avoided, and those of silver or glass used, because in these it may be boiled for any length of time, without being decomposed; and that as the intention of the operation is to perfectly saturate the cream of tartar, the boiling must be continued till this saturation be effected, which requires a long time, when the glass of antimony is grossly pounded, but a much shorter time when it is well porphyrised. Macquer, in the Chemical Dictionary, observes, that we are not certain that the emetic tartar, prepared by saturating tartar with glass of antimony, has always an uniform and constant emetic power. And therefore he recommends the powder of algaroth, or mercury of life, which, however dangerous in itself, may be rendered safe, by washing it with a little fixed alkali, which will

separate all that marine acid that communicates to it a certain degree of caustic quality. The powder thus washed, he says, is altogether soluble by cream of tartar, and convertible into a soluble emetic tartar, perfectly neutral, by boiling it, and saturating it with cream of tartar, and treating it in the manner above directed, for the preparation of emetic tartar with glass of antimony. The powder of algaroth, thus prepared, is a calx of antimony constantly of the same degree of emetic strength. The total evaporation of the fluid appears to be the best way of securing uniformity of strength to the medicine; and the solubility of the compound affords one of the best means for estimating its strength, or the degree of its impregnation with the antimony.

Dr. Saunders relates, that an ounce of cold water, about the middle temperature of the air, dissolved, of some of the common emetic tartars of the shop, not thirty-two grains, or one-fifteenth of its own weight; whereas of a well saturated sort, which he had himself prepared by long boiling, the same quantity of water dissolved fifty-two grains, or near one-ninth of its own weight.

The best way, probably, of obtaining a saturated and uniform preparation of this kind, would be to digest the common emetic tartar in eight times its weight, or less, of cold water, and evaporate the filtered yellow solution to dryness; or to continue the boiling of the glass of antimony and tartar for twelve hours, or longer, adding water occasionally to keep the tartar always dissolved, and at length to let the water waste so far, as not to exceed eight times the quantity of the tartar employed, after which the liquor is to be suffered to cool, and then filtered and evaporated. The dose of this preparation, as an emetic, is from two or three to six or eight grains. It may be given also as an alterative, or diaphoretic, in doses of a quarter of a grain, or half a grain, or more, and added, in the quantity of a grain or two, as a stimulus to the milder vegetable cathartics. Lewis's Mat. Med. by Aikin.

TARTAR, *Foliated*, is a preparation of tartar with distilled vinegar, which reduces it into white leaves. See ACETAS POTASSÆ, and TERRA FOLIATA.

TARTAR of Iron. See TARTRITE of Potass and Iron.

TARTAR, *Oil of*, is the salt of tartar exposed to the air for some days in an open vessel, in a moist place, till it dissolve into a fluid; though it is improperly called an oil, being no more than a dissolved salt.

Oil of tartar *per deliquium* is held the best counter-poison to corrosive sublimate.

TARTAR, *Regenerated*. When cream of tartar has been made soluble by any alkaline substance whatever, it may be revived, or regenerated, into cream of tartar again; its acid in this state has dissolved the alkaline matter presented to it, and that has been itself attenuated in such a manner as to render it capable of insinuating itself between the molecules or integrant parts of the constituent matter of the cream of tartar; on this only depends the solubility of this preparation: and to render the whole of its primitive nature again, there requires no more than the addition of a new acid, which shall free the tartar from this alkali; but this must necessarily be stronger than that naturally in the tartar. Thus spirit of nitre, or oil of vitriol, regenerate the soluble tartar in a moment, as being more powerful acids than that in the cream of tartar, and therefore taking from it all its alkali. The acid of distilled vinegar, which is not only a vegetable acid, but the same with that of tartar, is also able to regenerate the soluble tartars. It might seem wonderful that this should be able to effect this change without any superiority of force: but it is to be observed, that in the

TARTAR.

cream of tartar the acid has a terrestrial and alkaline basis, which is natural to it in that form; but in the state of soluble tartar it takes a new alkaline basis, which is not natural to it: and when we view the process in this light, it does not appear wonderful, that an acid of its own kind should be able to take away from it this artificial alkaline basis, though it was not able to take from it the natural one. Mem. Acad. Par. 1733.

This second or artificial basis is different, according to the different alkalies which have been employed to render the tartar soluble, and consequently the same acid may attach itself more to one than to another of those alkalies, or quit them the more or less easily. There is one kind of soluble tartar, however, which is not to be regenerated at all; this is that which is made with borax.

Dr. Huxham says, he has often experienced the good effects of regenerated tartar in the cure of obstructions of the bowels, and for sluggish humours. See *Acetate of Potash* under SALTS, and *TERRA Foliated*.

TARTAR, *Salt of*, is made of tartar washed, ground, purified, or cream of tartar, and calcined either *per se* or with nitre, by a reverberatory fire; or it is made by pulverizing what remains in the retort after the distillation of tartar, and calcining it as above by a reverberatory fire. On the one or the other of these preparations, they pour a great quantity of hot water, to make a ley of it; this they filtrate, and evaporate the liquor by a sand-heat, till the fixed salt be found at the bottom of the vessel. This is the pure alkali, or fixed salt of tartar. See *CARBONATE of Potash* under SALTS, and *SALT of Tartar*.

TARTAR, *Soluble*, (see *Tartrate of Potash* under SALTS, and *TARTRITE of Potash*,) may be made by the following process: Take of an alkaline fixed salt, a pound; of water, a gallon; and having dissolved the salt in this water boiling, throw crystals of tartar in powder as long as any fermentation is raised, which usually ceases before thrice the weight of the alkali is thrown in. Then strain the liquor through paper, and after due evaporation set it by for the salt to crystallize, or else evaporate the liquor wholly away, that the salt may be left dry.

This salt, by the action of the alkali on the acid of tartar, being freed from those gross terrestrial parts, with which the crystals of tartar, how pure soever, remain still charged, dissolves readily, and keeps suspended in cold water.

The several alkaline salts, that of tartar itself, the common pot-ashes, borax, &c. all make a very good soluble tartar; and not only these, but the common terrestrial alkalies, whether of the mineral kingdom, as chalk or lime; or of the vegetable, as the ashes of plants after elixivation; or of the animal, as oyster-shells calcined or not calcined, and hart-horn: all these give a better or worse soluble tartar; but of these, none succeeds so well as the oyster-shell, after it has been calcined; the soluble tartar, prepared with this, costs also greatly less than when prepared with salt of tartar.

In wood-ashes there is always a part, which when mixed with water swims, and is suspended in it a long time, and at length subsides into a kind of soft and impalpable matter; and another part, which subsides readily to the bottom, and feels rough and harsh. It is the first of these substances alone, which being mixed with cream of tartar, renders it soluble: the other part will not mix with the cream of tartar, or produce any such effect, unless reduced to the nature of the first, by repeated and violent calcinations, and then only a part becomes so altered, the whole never is so. It appears that the first portion has been wholly divested of its acid by the fire, and thence is become susceptible of the impression of the weakest acid, such as is that of the cream

of tartar, but in the second, or coarser part, the acid it naturally contained remains fixed and concentrated, so that it is not susceptible of any impression from the weak acid of the cream of tartar. Mem. Acad. Par. 1733.

The different kinds of soluble tartar have also their different degrees of solubility, or different readiness to run into a liquor *per deliquium*. The most easily soluble of all are those made with chalk, with lime, and with wood-ashes; and that which is most difficultly so, is the kind made with borax; it will at length run however, and is truly soluble tartar.

For the chemical and medical properties of this salt, see *Tartrate of Potash* under SALTS, and *TARTRITE of Potash*.

TARTAR, *Vitriolated*, which some call *magistry of tartar*, is a neutral salt, composed of a vitriolic acid, saturated with the fixed alkali of tartar, or with any other pure vegetable fixed alkali.

Vitriolated tartar may be decomposed by nitrous acid in the following manner, according to M. Baumé. Equal parts of both are put into a matras, and heated till the salt be dissolved. From the liquor when cold, true crystals of nitre may be obtained. And according to M. Margraaf, vitriolated tartar may, in the same method of treatment, be decomposed by marine acid.

This salt is not of any use in the arts, and little used in chemistry. It is chiefly employed in medicine. Like the other neutral salts, with bases of fixed alkali, it is aperitive in small doses, as a gros, or 59½ grs., and it is laxative, when taken from 6 to 12 gros. See *Sulphate of Potash* under SALTS.

The chemists have sometimes boasted of great virtues, in what they call the magistry of this salt; this is the earth precipitated in the making of it. It is the opinion of some ingenious authors, that all fixed salts are produced by a blending together of the acid and alkaline salts, which the plants they are obtained from originally contained, with some earth. The making of this preparation of tartar and vitriol, gives great strength to this opinion by means of this magistry; which shews, that an earth necessary to the cementing a mixture of an acid and an alkali into a neutral salt, may exist even in one of the principles themselves, though unseen by us; and that, as in the present instance, in so large a quantity, as not only to be sufficient for the combining the two volatile substances into a fixed one, but even to leave a remainder of it, that was not necessary.

While the acid of vitriol is poured upon the dissolved salt of tartar, or its oil *per deliquium*, for the making of this salt, during the great effervescence between the acid and the alkali, there is a precipitation made of an earth, for the separation of all which great care is to be had to the degree of saturation of the alkali with the acid. This earth afterwards may be severed by filtration. This earth is precipitated, not out of the spirit of vitriol, but out of the salt of tartar; and this experiment shews, that this fixed salt did originally contain that earth, which, according to the system of the formation of fixed salts out of volatile ones, originally residing in plants, must necessarily be mixed with them, and which, not being able to mix with the acid, is separated and thrown off in the conflict, in which the acid mixes itself with the rest.

This earth is what is pompously called the *magistry of vitriolated tartar*; but it is very wrong to give that name to an earth which has none of the properties of that or any other salt; and they greatly deceive themselves and their patients, who prescribe it instead of the salt itself. Its saline taste, probably, has induced them to think that it possessed great virtues; but this is not innate but adventitious.

tious, and the effect only of the fluid in which it was precipitated: it cannot but have some of the salts of that fluid hanging about it, when first made; but these may, by repeated washings, be carried wholly off, and the magistry will then remain a pure simple earth, and shew itself to be no other than that earth, which may be properly called the earth of all fixed salts; and which, though necessary to give the salt of tartar its form as a lixivial salt, yet being not necessary to it in its new form of a neutral salt, is deposited in the making it into that form. It yet remains to be proved by more numerous experiments, that the fixed salts of plants owe that form only to a fixing earth, combining their two original volatile principles into a fixed mass; for if this be truly the case, there then needs no more to the volatilizing them again, but the divesting them of this earth. Phil. Transf. N^o 90.

TARTAREOUS or TARTARIC Acid, was first separated from cream of tartar, and obtained in a solid crystalline form, by a method which was discovered by Scheele, and which, with little variation, is as follows: it very much resembles the mode used by the same ingenious chemist in obtaining the citric acid: Having analysed cream of tartar (see Swedish Transactions, part iii. for 1770.), he found that this is not a pure acid, but a compound salt, containing the fixed vegetable alkali, united with a superabundance of the tartareous acid, and therefore, that it differs from soluble tartar only in the proportion of acid which it contains. For obtaining this acid, he dissolved any given quantity of the cream of tartar in boiling water, and whilst boiling, added gradually some clean powdered chalk. Upon this a copious effervescence will arise, and the addition of chalk must be continued till this ceases, when the mixture may be set by to cool. It then contains a white dense sediment, which consists of the lime of the chalk, united with the excess only of the acid of the cream of tartar; and the supernatant liquor is, therefore, a solution of the cream of tartar deprived of its excess of acid, or neutral tartrate of potash, or soluble tartar, as it is also called, and which may be obtained crystallized by subsequent evaporation. Wash the precipitated tartrate of lime repeatedly with cold water, then put it into a glass vessel, and add to it a diluted sulphuric acid, composed of as much concentrated acid, as is equal to the weight of chalk employed in saturating the cream of tartar, mixed with four or five times its weight of water.

The sulphuric acid having a stronger affinity for the lime than the tartareous acid has, totally decomposes the tartrate of lime, during a digestion of two or three days (or in a shorter time if assisted by a gentle heat,) and the white sediment, though it does not alter its appearance, is changed to sulphate of lime, whilst the supernatant liquor contains naked acid of tartar. Then pour off the clear liquor, wash the sulphate of lime to extract all the adhering acid, and add the washings to the former liquor, and evaporate the whole, (at first with a boiling heat, and as it concentrates, with a much gentler warmth,) till it is of a thick syrupy consistence, and then set it by for some hours, that all the selenite, which it may hold in solution, may be deposited. Then again dilute the mixture with cold water sufficient to redissolve every thing but the selenite, and slowly evaporate the solution to a syrupy consistence, and after some hours it will deposit the pure tartareous acid in crystals, which are generally pretty large irregular hexahedrons. Cream of tartar decomposed in this way by chalk (and therefore only partially) will yield about a third of its weight of the crystallized acid. This quantity however must not be taken as the proportion of the acid in cream of tartar, for much of the weight of the crystallized acid is water of crystalli-

zation, whereas the cream of tartar contains very little water.

In the above detailed method of obtaining tartareous acid, chalk, or carbonate of lime, is used to decompose the cream of tartar, which it does merely by engaging the excess of acid, and leaving the remainder of the salt in the state of tartrate of potash. But if quick-lime be substituted to the chalk, the whole of the cream of tartar is decomposed, a much larger quantity of tartrate of lime, and consequently of tartareous acid, is obtained, and the supernatant liquor is a solution of caustic potash. It has been found however by Vauquelin, that the potash retains a small quantity of tartrate of lime in solution, so that when the alkaline liquor is evaporated nearly to dryness it gelatinizes by cooling, owing to the separation of this calcareous salt. It may be decomposed by carbonate of potash or soda, which produces carbonate of lime and tartrate of the alkali employed: or the tartareous acid may be destroyed by calcination, and the lime, carbonated in the process, will remain.

Calculating from the observed proportions of acid in the tartar, and of chalk required in the first-mentioned process, and of pure lime in chalk, we may estimate that all the acid in 100 parts of cream of tartar (which Thenard reckons at 57 per cent.) will require full 42 parts of pure lime for its saturation, and somewhat more lime should perhaps be added to ensure the complete decomposition of the tartar. The lime should be previously slaked and mixed with sufficient water to bring it to the consistence of paste.

Lowitz has proposed another method, which is perhaps preferable in every respect, except that it is somewhat more expensive, and that no caustic alkali is obtained. It consists first in decomposing the cream of tartar by chalk in the usual way, added as long as any effervescence takes place; and then pouring into the filtered supernatant liquor muriate of lime, as long as any precipitate falls down. By this means the tartrate of potash in liquor is totally decomposed, muriate of potash remains in solution, and the precipitated tartrate of lime is added to that produced by the chalk; and both are afterwards decomposed by sulphuric acid in the usual way. The same chemist also advises to add to the solution of tartareous acid in the last part of the process a quantity of charcoal powder, (the depurating power of which has been mentioned under CARBON.) This, however, is certainly not essential to the obtaining a perfectly fine colourless crystallized acid, and, we believe, is seldom, if ever, used.

The tartareous acid has a strong acid taste, and is soluble in five or six parts of water, and in a much less quantity of boiling water. The crystals are permanent in the air.

When heated *per se* in a retort with a receiver, this acid melts, boils up, and exhales a four pungent vapour, which condenses in the receiver into a red acid empyreumatic liquor, equal to about a quarter of the weight of the tartareous acid.

This liquor has a pungent, acid, and empyreumatic taste, strongly reddens litmus, and effervesces with the alkaline carbonates. It is called the Pyrotartareous acid, which has not been much examined. The other products from the distillation of tartareous acid, are a large quantity of carburetted hydrogen and carbonic acid gas, and a soft spongy coal is left in the retort, which, heated in the open air, burns with scarcely any residue.

The tartareous acid, besides being found native in some vegetable juices, and in the deposit from wine during and after fermentation, is also produced by the action of nitric acid on alcohol. A further digestion of tartareous with nitric acid converts the former into oxalic acid, and a still

further digestion changes the whole of the vegetable acid into vinegar. These curious experiments, which were at first noticed by Scheele, have been fully examined by Hermbstaedt, and other chemists.

Tartareous acid is composed, according to Fourcroy and Vauquelin, of 70.5 of oxygen, 19 of carbon, and 10.5 of hydrogen, and differs from the oxalic acid in containing more carbon and less oxygen. The order of affinity of this acid for the several bases is, according to Thenard, lime, barytes, strontian, potash, soda, ammonia, magnesia, and alumine. Aikin's Dict.

For the combinations of the tartareous acid with the several bases, we refer to the article TARTRATES or TARTRITES.

TARTARHAN, a word used by some authors to express spirit of tartar.

TARTARI, in *Geography*, a mountain of Dalmatia; 8 miles N. of Trau.

TARTARIAN OAT, in *Agriculture*. See OAT.

TARTARIZATUS CHALYBS. See IRON, in the *Materia Medica*, and TARTRITE of Potash and Iron.

TARTARIZING, a term used by some writers for the act of refining or purifying, by means of salt of tartar.

TARTARO, in *Geography*, a river of Italy, which rises in the Veronese, and running easterly, traverses the Polese de Rovigo, passes by Adria, and soon after separates into two branches, one of which runs into the Adige, and the other into the Po.

TARTARON, a sort of fine cloth or silk, mentioned in the stat. 4 Hen. VIII. c. 6. Blount, Cowel.

TARTARUGA, in *Zoology*, a name by which the Portuguese in America call a species of tortoise, known among authors by its Brazilian name *jurucua*.

TARTARUM TARTARISATUM, *tartarified tartar*, in *Chemistry*, the name of a preparation of tartar; the manner of doing which is given by Boerhaave, and is as follows: Reduce some of the purest white tartar to powder, and boil this powder in ten times its weight of water in a large copper vessel, till it appears perfectly dissolved: let it after this continue boiling till the liquor becomes tolerably transparent, and of an acid taste; then drop into it from on high oil of tartar *per deliquium*, the liquor being still kept boiling: upon the falling in of each drop there arises a great ebullition, occasioned by the meeting of the acid and alkali. Large bubbles appear on this, and in these the chemists have imagined they found the figures of clusters of grapes.

The operation is to be patiently continued till there is no more effervescence made by the falling in of the drops of the oil. The acidity of the tartar will be then so perfectly saturated with its own alkali, that it will appear neither acid nor alkaline, but a third salt; great caution however must be used in observing the true point of saturation, otherwise the salt will be when finished either a little acid, or a little alkaline, as the one or the other exceeds. The liquor is to be then strained several times through a flannel, till perfectly clear: it is of a deep brownish colour, and brackish saline taste, but has no scent. If this be evaporated to a pellicle, and set to crystallize, it forms a salt which is a tartar, easily soluble in water, even when cold; and very properly to be called soluble tartar. Boerhaave Chem. part ii. p. 161.

TARTARUS, in *Ancient Mythology*, is one of the general divisions of the subterraneous world, or the place of torments. The origin of the fable of Tartarus is traced in Hesiod's account of the war of Jupiter against his father Saturn and the Titans, who, after he had gained a victory over them, was driven from Olympus, and condemned to the bottom of Tartarus, in the extremities of the earth. Typhon also, threatening to deprive Jupiter of his empire,

VOL. XXXV.

was plunged into the same abyss. The abbé Banier has given the following explication of this fable. The Greeks, he says, regarded the places situated to the east of them as higher than those that lay westward; and hence they took the former for heaven, and the latter for hell. According to this notion, they placed their hell either in Spain, the residence of Pluto, or in Italy, and lastly in Epirus, or rather in Thesprotia, all which countries were situated to the west of Greece. Now as the Titans, in the several conspiracies they formed, were obliged to enter into Italy and Spain, the poets fabled that they were precipitated into the gulf of Tartarus; but as their notion of Tartarus was taken from Tartessus, a river of Spain, on the banks of which Pluto resided, it is no wonder that the Titans, having been defeated near that river, were fabulously said to be plunged headlong into the Tartarian gulf.

The other two divisions of Aides, according to Virgil, are Erebus and Elysiun. The prince or judge who presides over Tartarus, is Rhadamanthus. The miserable inhabitants of this horrid region are of two sorts, *viz.* the souls of such as are tormented, and the infernal deities, called the Furies, who attend there either to inflict or aggravate their torments.

Virgil distinguished those that are tormented in Tartarus, into two general classes; the first, of such as have been ungrateful or impious towards the gods; and the second, of such as have been mischievous and hurtful among men: those of the latter, more particularly, who hated their brethren, used their parents ill, or cheated their dependents; who made no use of their riches; who committed incest, or disturbed the marriage union of others; those who were rebellious subjects, or knavish servants; who were despisers of justice, and betrayers of their country; and who made and unmade laws, not for the good of the public, but only to get money for themselves. All these, and the despisers of the gods, of whom the rebel giants occupied the chief class, Virgil places in Tartarus, and in that vast abyss, which was the most terrible part of this infernal region. The great road that passes through Erebus, is represented as divided into two; of which the right-hand road leads to Elysiun, or the place of the blest; and the left-hand road to Tartarus, or the place of the tormented. Virgil *Æn.* vi. v. 540—549. 566—580. 607—624. Spence's *Polymetis*, p. 259, &c.

TARTARS, or TATARS, in *Geography*, a comprehensive denomination, including all tribes beyond Persia and India, as far as the Eastern ocean, however differing from each other in regard to their origin, language, manners, customs, and religion. It is now known, however, that the Tartars compose a distinct nation, which originally belonged to the grand Turkish stock. The name, it is said, may originate either from a Turkish horde, which bore this denomination; and accordingly it is alleged, that the Yakutes have among their deities, a Tatar, who probably enjoys that honour as the patriarch of the nation; or from the Chinese, who call all their neighbours, without distinction, Tata or Ta-dse, in proof of which derivation it is intimated, that the Persians and Arabians know nothing of the Tartars under that appellation. It was first brought into general use in Europe after Baaty's incursion into Hungary, under king Frederic II. Whatever be the origin of the name, it seems to be clear, that the Tartars are of Turkish origin, and that their proper name was Turk or Turkman, and not Tatar. In this opinion, the learned men of their own nation concur: to which circumstance it may be added, that the Tartarian language is merely the old Turkish; and the modern Ottoman Turks speak the Tartarian tongue only in another dialect. And the Tartars pretend to derive their descent

R

from

from Turk, the eldest son of Japhet: and although from the time in which Jenghis Khan subdued all Tartary and a great part of Asia, and made irruptions even into Europe, they have been known by the name of Tartars, to which that of Monguls or Moguls, of whom he was properly the prince, appeared inferior; nevertheless the Tartars preserve among themselves the name of Turks. See MONGOLES.

The first known mother-country of the Turks or Tartars lies somewhere in the countries on the eastern and northern sides of the Caspian, where their descendants are still situated. In ancient times they were spread from the Oxus or Gihon into the Mongoley and the Orenburg territory; that is, in regions where they had constantly ambitious and domineering nations for their neighbours and enemies: on the E. the Chinese; on the S.W. the Persians, Macedonians, Romans, Partho-Persians, and Arabians; and towards the N.E. the Mongoles. Here they served from time immemorial as a mound against the incursions of the nations which could penetrate from the E. to the W., or contrariwise, till at length the Mongoles, like a rushing stream that has burst its banks, swept away all opposition.

The Tartars, says baron de Tott, in his "Memoirs," (vol. i.) have the best title to the highest antiquity. To this purpose he observes, that the flat high land of Tartary, which extends to the north, and the chain of the mountains of Caucasus and Thibet, continued almost as far as the peninsula of Corea, (if we may judge by the course of the water, which, from the centre of Asia, spreads to the S. and to the N. of that part of the globe,) present the highest portion of land which separates the Indian seas from those of Kamtschatka. This observation, it is alleged, seems to prove, that the country at present occupied by the Tartars, must have been the first land discovered in Asia, the first inhabited, the first source of population, and the origin of those emigrations, which, constantly repelled by the Chinese wall, and the defiles of Thibet and Caucasus, have passed from the north of Asia into Europe. (See HUNS.) However, the annals of the Tartars are involved in considerable uncertainty before the time of Jenghis Khan, who was elected grand cham (khan) by the chams of the different tribes, and was only chosen to be the king of kings, because he was the most powerful among them. It is well known, that Jenghis Khan conceived and executed projects of usurpation, by which he formed the most extensive empire known in history.

The Tartars began to acquire some importance in history, after the time of their subjugation by the Mongoles; but from the moment that their history excites attention, it ceases to be the history of a peculiar nation. Distributed under the banners and commanders of the Mongoles, these enjoy with posterity the glory of their conquests, while the Tartars are constrained to lend their name to the devastations with which both nations every where marked the bloody progress of their armies. (See MONGOLES.) Subjugated in their conquered countries, and even forced from a great part of their old habitations, some few of the Tartar hordes (few in reference to the whole Tartarian tribes,) have preserved their independence: *i. e.* those who inhabit the south-western part of the former Great Tartary, towards the Persian, Indian, and Soongarian borders. Here we find the great Kirghisian horde, the Bukharians, the Khivans or Khivines, the Karakalpaths, Truchmenes, Tashkantians, Turkestans, Arabians, and some other races, which still form distinct states, and retain a kind of national liberty; but they exist in so feeble a state, that they are obliged to seek protection sometimes from one power, and sometimes from another. The whole remnant of this nation, once so

great, subsists under foreign sovereignty. Many hordes belong, either as subjects or as dependent wards of the Russian empire; others are, in like manner, appanages to the Ottoman Turks, or subject to the Great Mogul, to China, and to Persia.

Mr. Strahlenburg, a Swedish officer, who resided some years in Siberia, places them in six classes: the first, containing seven different nations, all in the dominions of Russia, *viz.* the Mordvines, who dwell in the government of Nizgorod; the Tcheremisses, or Czeremisses, in the government of Kazan; the Permians, in the government of Perm; the Votiaks, in the government of Viatka; the Vogouls, who dwell on both sides of the mountains, which formed a separation between Russia and Siberia; the Ostiaks, who dwell on the coasts of the river Oby; and the Barabintzi, who inhabit the country between Tara and Tomsk. The second class of people, called Tartars, includes the Budziaks, which dwell on the coasts of the Black sea; the Crim Tartars, who inhabit the province of Taurida; the Kuban Tartars, on the borders of the Kuban river; and the Tartars of Daghestan; the Nogais, or Tartars of Astrachan, of Kazan, and Upha; the Baschkirs and the Tartars about the towns of Tiumen, Tara, Tobolsk, and Tomsk; the Usbeck Tartars, the Turcomans, the Kurguis, the Karakalpas, the Sayantzi, who dwell near the head of the Yenissey; the Kirghises, who occupy the mountains south of lake Baikal; the Burats; the Arintzi, who also inhabit near the same mountain; and the Yaktai, more to the north, on the sides of the Lena. The third class includes the Samoiedes, on the coast of the Frozen sea, from Archangel to the Lena. The fourth class includes the Kalmucks and Monguls, who were formerly but one people. The fifth class includes the Mantcheux and the Tunguses. The sixth class contains the savage nations on the north-east coast of Asia, as the Tschutki, &c. with the inhabitants of Kamtschatka, and the Kurile islands. Of these, the first, third, and sixth class are subject to Russia, except that a small part of the second is independent. The fourth is partly independent, and partly subject to China. The fifth class is wholly subject to China.

Abulgasi, in his account of the Turkish stems, mentions among them the Tartarian as one of the most ancient and famous, and derives its origin from a khan of the name of Tatar. This stem, which in process of time increased to 70,000 families, was at first governed by its own commander, and afterwards divided into various branches, dispersed into several and very distant regions, by which dispersion their power was weakened. The most considerable branch settled on the borders of Kitay (China), and fell under the sovereignty of that empire, against which it frequently rebelled, and thereby gave occasion to ruinous wars. At the time of Jenghis Khan, some Tartars dwelt on the Oxus or Amur, who were tributary to the emperor of Kin, reigning in Kitay.

The Tartars who belong to the Russian empire inhabit the northern coasts of the Euxine and the Caspian, the north side of the mountains of Caucasus, the extensive steppes from the river Ural to the Soongarey, the southern Ural, in Siberia the southern frontier mountains and steppes from the Tobol quite over the Yenissey, and the deserts in the middle region of the Lena; and some few Tartar colonies are dispersed among the Russian habitations, particularly in the governments of Upha, Kazan, and Tobolsk. Frequent memorials are found in various regions of their ancient grandeur, magnificence, and culture, some of which are demonstrably of 1000 years' antiquity. The branches of this nation which belong to Russia are the proper Tartars, or the

descendants of those two great states, which the successors of Jenghis erected on the Volga and in Siberia (see KAPTSCHIK, and the sequel of the article); the Nogayans, the Mefchtscheryaks, the Baschkirs, the Kirghises, the Bucharians, the Yakutes, the Teleutes, and in part the tribes of Caucasus. The Kaptschak Tartars are reduced to a small residue, intermixed among the Baschkirs and Kirghises. The Kazan Tartars are also a feeble remnant of what they formerly were, and are dispersed in the governments of Kazan, Simbirsk, Riefen, Viatka, Perm, and Upha. The Astrachan Tartars are for the most part Nogayans: they are distinguished into town, village, and tent Tartars. The first dwell in Astrachan, the second in six villages near Astrachan, and the third wander about the Caspian. In 1772, those of the two former classes were only 1200, and of the tent Tartars scarcely 2000 kettles, or families. For the state of the Krim Tartars, see CRIMEA. The stems of the Siberian Tartars, who are numerous, are the Turalinzes, one of the first colonies that became permanent in Siberia, when the Tartars subjugated the country in the 13th century; the Tobolskian Tartars, who dwell on the river Tobol; the Tomskian Tartars, who inhabit both sides of the river Tom, above and below the city of Tomsk; the Krasnoyarskian and Kufnetzian Tartars; the Tartars of the Oby; the Tschulymskian Tartars, inhabiting the territory along the river Tschulym; the Barabinzes, between the Oby and Irtysh; the Katschinzes, on the left shore of the Yenissey; the Kistim and Tulibert Tartars, on the left bank of the Tom; the Biriuffes; the Abintzes; the Sayane Tartars; the Beltirs, the Verchotomskian Tartars, and some other insignificant stems. For the other branches of the Tartars who inhabit Russia, we refer to the several articles, NOGAYANS, &c. &c.

The Tartars who are Mahometans bordering on Russia, but independent of that crown, take every opportunity of robbing their neighbours: the Kalmucks and Monguls are very different in their behaviour, living quietly on the produce of their soil, without doing injury to others. The Tartars of Asiatic Russia are likewise represented as a quiet, inoffensive people, living chiefly by the chase and fishing. See the following articles. See also MANDSHURS, MONGOLES, TUNGUSES, &c.

TARTARY, or TATARY, a vague name, as it relates to Asiatic Russia, which cannot be used with precision as descriptive of any particular country: instead of it might therefore be substituted names derived from the seats of the chief nations, as Tungusia or Mandshuria in the east, Mongolia in the centre, and Tataria in the west. In a general sense, however, whilst the name remains, it may include three distinct countries, *viz.* Chinese Tartary, Independent Tartary, and Russian Tartary.

TARTARY, *Chinese*, according to the abbé Grofier's description, is bounded on the north by Siberia, on the east by the gulf of Kamtschatka and the Eastern sea, on the south by China, and on the west by the country of the Kalmucks, who are established between the Caspian sea and Kashgar. The different tribes which at present inhabit it, were formerly comprehended under the general name of Mongul or Mogul Tartars, a warlike and formidable nation, who, on the one hand, conquered Hindooistan, under the famous Jenghis Khan, and on the other, subdued China. It was in the 13th century that the Monguls took possession of the latter empire; but after having reigned there for 100 years, they were expelled by the Chinese, in the year 1368. The fugitives took different routes; some went towards the Eastern sea, and established themselves between China and the river Saghalien; the rest returned westward to their former country, where, intermixing with the Monguls that remained,

they soon resumed their ancient manner of living; those who settled towards the east, having found the country almost a desert, and without inhabitants, retained the same customs which they had brought from China: hence these two Mongul nations differ at present in language, government, religion, and customs. Those of the east retain their ancient name of Mongul, or Mogul Tartars; the rest are known by the name of Mantchew, or Eastern Tartars. Chinese Tartary is therefore divided into two parts, the Eastern and Western. Eastern Chinese Tartary extends, north and south, from the 41st to the 55th degree of north latitude; and east and west, from about the 120th degree of longitude, as far as the Eastern sea. It is bounded on the north by Siberia, on the south by the gulf of Leao-tong and Corea, on the east by the Eastern sea, and on the west by the country of the Monguls. The Tartars who retired hither, after their expulsion from China, in the year 1368, immediately began to build cities, towns, and villages, and to cultivate the earth, after the manner of the Chinese, among whom they had lived: hence the greater part of them have remained fixed, and are much more civilized than the rest of the Mongul nation. They were at first governed by particular khans, each independent of the other; but since that of Ningouta (who was the most powerful among them) took possession of China, about the middle of the 17th century; the emperor, who is still one of his descendants, has reduced under his dominion all the other khans of this part of Tartary: this prince governs it immediately by himself, and sends thither governors and officers, as into all the other provinces of the empire. The country of the Mantchew Tartars is divided into three grand departments: *Chen-yang*, *Kirin*, and *Tütcicar*; which see respectively.

Ningouta, already mentioned, which is considered as the cradle of the present imperial family, is surrounded by a wooden wall, consisting of stakes, touching each other and twenty feet high, and also another palisado without this, a league in circumference, and having four gates, corresponding to the four cardinal points. The Mantchew Tartar, who resides in it as lieutenant-general, extends his jurisdiction over the adjacent country, and all the villages of Yupi-tafe, and some other petty nations that inhabit the banks of the rivers Oufouri and Saghalien, and along the sea-coast. The Tartars of Yupi-tafe are peaceful in their disposition, but stupid and clownish, without letters, and without any religious worship. They sow neither wheat nor rice, nor any thing else except tobacco, which they cultivate in some of the fields surrounding their villages. They are supplied with fish from the river Oufouri, and this is their only food: nor have they any clothes besides those which they make of their skins, dressed, dyed of three or four colours, and artfully sewn together with a thread cut from an exceedingly fine skin. The women suspend from the bottoms of their long cloaks pieces of money and little bells; and the tresses of their hair, which hang over their shoulders, are loaded with small mirrors, rings, and other toys. Of one part of their fish, which they employ the summer in taking with harpoons and small nets, they make oil for their lamps; another supplies them with food; and a third part is reserved for winter, when the ice prevents them from fishing. Beyond the Yupi-tafe Tartars are the Ketcheng-tafe Tartars, who inhabit both banks of the river *Saghalien-oula* (which see), and extend as far as the Eastern sea. These Tartars are less clownish than the preceding, and employ much of their time in hunting fables.

The Mantchews, dispersed throughout Eastern Chinese Tartary, have neither temples nor idols; they adore (as they express it) only the "emperor of heaven," to whom they

offer sacrifices: but since they have entered China, some of them worship the god "Fo," and other idols revered in the empire. When they became masters of China, they pretended to a celestial extraction, and placed a god at the head of their race. Since the Tartars have had possession of the throne of China (see CHINA), their language has become familiar at the court of Pe-king. This language they are very careful in preserving, and it is said that it may be much more easily acquired than that of China. Although the Tartars have only one kind of characters, they write them in four different ways, which they write with a pencil, or a kind of pen, formed of the bamboo reed, and which they can read with equal ease when reversed.

TARTARY, *Western Chinese*, is called also the country of the Mongoles, or Moguls; for an account of which, see the article MONGOLES. See also KALKAS, KALMUCKS, and KONONOR. We shall here add that the country of the Ortous, who inhabit N. of the great wall, and W. of the Moguls properly so called, is 110 leagues in extent from E. to W., and 70 from N. to S. These people are divided into six standards, which comprehend 166 companies, each composed of 150 heads of families. The Ortous are of a free disposition, very lively, and never subject to melancholy, and may be justly called the "French of Tartary."

Wild animals of various kinds are innumerable in the plains and forests of Tartary. The country abounds with game, and all the animals that are hunted in Europe, with large flocks of yellow goats, wild mules, wild camels, and horses; an animal resembling the elk, a species of lynx, whose skin is highly valued, tygers of prodigious size and agility, whose skins are used for ornament; a species of leopard, and stags. Some of their rivers wash down gold mixed with their sands; and they are acquainted with the method of applying it to use, and of forming it into vases and small statues, of which they often make offerings to their idols. It appears that the use of gold is very ancient among them.

The vulgar name of Tartary, or Tatar, says Mr. Pinkerton, was originally extended over the vast regions lying between Thibet, China, and the Arctic ocean; and from the Black sea in the west to the utmost bounds of north-eastern discovery in Asia. But as geographical knowledge has improved, the northern part has acquired the name of Siberia, while the southern is distinguished by the appellation of Western and Eastern Tartary. But in this part, which might more properly be named Central Asia, the Tartars, properly so denominated, are few, the most numerous tribes being Monguls in the west and Mandshurs in the east. See MONGOLES and MANDSHURS.

The wide and interesting portion of Asia, formerly known by the appellation of Eastern and Western Tartary, but now properly styled Central Asia, and comprehending the Middle Mongolia and the Eastern Mandshuria, which has repeatedly sent forth its swarms to deluge the arts and civilization of Europe, says the geographer above cited, extends from E. long. 72° to 145°, a space of not less than 73° of longitude, which, at the medial latitude of 45°, will yield about 3100 geographical miles. The breadth from the northern frontier of Thibet to the Russian confines, is about 18°, or 1080 geographical miles. The limit between Russia and Chinese Tartary is partly an ideal line, and partly the river Argoon, which joined with the Onon, constitute the great river Amur. From the treaty published by Du Halde it appears, that the river Kerbatchi, the nearest to the river Chorna or Ourouon, and which discharges itself into the great river Saghalien-oula, was the Chinese definition of the boundary between the two empires, to which was added the long

chain of mountains above the source of the river Kerbatchi and the river Argoon. The eastern boundary is the sea, while the southern extends along the great Chinese wall, and the northern limits of Thibet. The western boundary is supplied by the celebrated mountains of Belur-Tag, or the Cloudy Mountains, which divide the Chinese empire from Balk, and the greater Bucharia; while the range on the W. of the lake Palkati separates the Kalmucks, subject to China, from the Kirguses of Independent Tartary.

The original population of Central Asia appears to have been indigenous. The west was partly held by the ancient Scythæ, seemingly a Gothic race, who were subdued or expelled by the Tartars, or Huns, from the east, pressed on the other side by the Monguls, beyond whom were the Mantchews, who, in the 17th century, conquered China. Pinkerton's Geography, vol. ii. See MONGOLES and MANDSHURS.

TARTARY, *Independent*, an extensive, celebrated, and interesting region, considered as distinct from Mongolia and Mandshuria, or as these countries have been less properly called, Chinese Tartary, and independent of the great neighbouring powers, China, Russia, and Persia: this country was probably the seat of the most ancient Persian kingdom, the possession of the Greek monarchs of Bactriana, and after many revolutions, distinguished by the wide empire of Jenghis or Zingis, and Timur. Its extent may be measured from the Caspian sea to the mountains of Belur, a space of about 870 British miles. From the mountains of Gaur in the S., to the Russian boundaries in the N. of the desert of Issim, it may be near 1500 British miles, of which a great part is desert. The chief divisions are the wide steppes, or barren plains in the N., held by three hordes of Kirguses or Kirghises, the Great, Middle, and Lesser, besides some small Tataric tribes near the sea of Aral. This portion was anciently called Turkestan, and its capital was Taraz. (See both these articles.) Southwards of the mountains of Argun, the land begins to become fertile along the river Sirr or Jaxartes, called also the river of Shush from the chief territory, and also on the banks of its tributary streams. Ilak and Shush, the most northern provinces on the Sihon, are followed by Fergana, and a district called Ozrusna, round a town of the same name. Divided from these provinces by deserts and mountains is the kingdom of Kharism, or Kharafm, which see. South of the range of the Ak Tam is the fertile region of Sogd, or Sogdiana, with its capital Samarcand. On the S., the provinces of Balk, Kilan, Tokarestan, and Gaur, terminate the bounds of Independent Tartary, here separated by deserts on the W. from the Persian province of Chorasan or Khorassan. See these articles respectively. See also BELUR-TAG, BUCHARIA, IMAUS, KIRGHISES, MASSAGETÆ, SCYTHIA, and UZBECKS.

TARTARY, *Crim.* See CRIMEA.

TARTARY, *Russian.* See RUSSIA and TARTARS.

TARTARY, *Little*, a name that has been given by some writers to the country containing the peninsula of the Crimea, the Kuban, a part of Circassia, and all the lands which separate the empire of Russia from the Black sea. This circuit, continued from Moldavia almost to Taganrog, between the 44th and 46th degrees of latitude, is from 30 to 40 leagues wide, and nearly 200 long. From E. to W. it includes Yetitcheoolai, Dgamboylask, Yedefan, and Bessarabia. The latter province, at present called Boodjak, is inhabited by Tartars, who, as well as those of the peninsula, have fixed habitations in their villages; but the inhabitants of the three other provinces have only felt-tents, which they carry wherever they please. Those people, called Noguais, and supposed to be Nomades, are settled, however, in the vallies that traverse their plains from N. to S.,

and their tents, ranged in a single line, form thus a kind of villages of 30 and 35 leagues in length, which distinguish the different hordes. Tott's Memoirs, vol. i. See CRIMEA and RUSSIA.

TARTAS, a town of France, in the department of the Landes, and chief place of a canton, in the district of Saint-Séver, divided into two parts, the first containing 1556, and its canton 6154 inhabitants, and 8 communes; and the second part containing 1656, and its canton 7952 inhabitants, and 12 communes: its whole territorial extent being 540 kilometres; 15 miles W.S.W. of Mont-de-Marsan. N. lat. 43° 50'. W. long. 0° 44'.—Also, a river of Russia, which runs into the Om, near Tartaskoi.

TARTASKOI, a town of Russia, in the government of Tobolsk, at the union of the Om and the Tartas; 40 miles W.S.W. of Kainfk.

TARTESSUS, in *Ancient Geography*, a town of Spain, in the part called Bœtica, situated between the two arms by which the river Bœtis discharged itself into the sea. One of these arms has disappeared, and the other still subsists and passes into the sea at San Lucan de Barrameda. Some geographers have suggested that Gades was the ancient Tartessus. Strabo intimates that anciently the river Bœtis was called Tartessus, and that the town of this name was afterwards called Cartheia. M. d'Anville gives the name of Tartessus to the island formed by the two branches of the Bœtis at its mouth.—Also, a mountain of Spain, in Bœtica.

TARTESSUS, *Isle of*, was situated near Gades, and is supposed to have been the Tarshish of the Phœnicians, to whom it was known about 1000 years B. C.

TARTI LAPIS, a stone mentioned by Ludovicus Dulcis, and some other authors, and said to be very beautiful, having all the colours of the tail of a peacock, and to have many medicinal virtues. It was probably some species of agate; but the short account given of it will not enable us to guess what particular kind.

TARTINI, GIUSEPPE, of Padua, in *Biography*, the greatest performer on the violin and composer for that instrument of the last century. We shall here only consider him as a practical musician, though he has distinguished himself as a theorist in a way superior to all other contemporary professors. See SYSTEM, and STILLINGFLEET.

This admirable musician and worthy man was born at Pirano, in Istria, in 1692. His father, having been a great benefactor to the cathedral church at Parenzo, had been ennobled in reward for his piety. Giuseppe was intended for the law, but mixing music with his other studies during the course of his education, it soon grew too powerful for the rest, and tyrannized over the whole circle of sister sciences. This is not so surprising as another strong propensity, which during his youth occupied his attention very much, which was *fencing*, an art that was not likely to become necessary to the safety or honour of a man of so pious and pacific a disposition, in a civil employment; and yet he is said to have equalled in this art even the master from whom he received instructions. In 1710 he was sent to the university of Padua to pursue his studies as a civilian; but before he was twenty, having married without the consent of his parents, they wholly abandoned him, and obliged him to wander about in search of an asylum; which, after many hardships, he found in a convent at Assisi, where he was received by a monk his relation, who, commiserating his misfortunes, let him remain there till something better could be done for him. Here he practised the violin, to keep off melancholy reflections; but being discovered on a great festival in the orchestra of the church of the convent by the accident of a remarkable high wind, which forcing

open the doors of the church, blew aside the curtain of the orchestra, and exposed all the performers to the sight of the congregation; when, being recognized by a Paduan acquaintance, differences were accommodated, and he settled with his wife at Venice for some time. This lady, indeed, was of the Xantippe kind, and being himself very Socratic in wisdom, virtue, and patience, her reign was unmolested by any domestic war, or opposition to her supremacy.

While he was at Venice, the celebrated Veracini arrived in that city, whose performance awakened an extraordinary emulation in Tartini, who, though he had been thought to have a powerful hand, had never heard a great player before, or conceived it possible for the bow to have such varied powers of energy and expression. He, therefore, quitted Venice the next day, and went to Ancona, in order to study the use of the bow in more tranquillity, and with more convenience than at Venice, as he had a place assigned him in the opera orchestra of that city.

This happened in the year 1714, the year in which he discovered the phenomenon of the third sound. It was at Ancona, and in the carnival of the same year, that he heard and perceived the extraordinary effects of a piece of simple recitative, which he mentions in his "Trattato di Musica." (See RECITATIVE.) It was likewise during his residence at Ancona, that, by diligent study and practice, he acquired sufficient abilities and reputation to be invited, in 1721, to the place of first violin, and master of the band in the celebrated church of St. Anthony of Padua.

By this time his fame was so extended, that he had repeated invitations from Paris and London to visit those capitals; but by a singular devotion and attachment to his patron saint, to whom he consecrated himself and his instrument, he declined entering into any other service.

Before the year 1728, he had made many excellent scholars, and formed a school, or method of practice, for the students on the violin, that was celebrated all over Europe, and which increased in fame to the end of his life.

The author of the compendium of his life informs us that his first book of solos was engraved at Amsterdam, 1734; the second at Rome, 1745; and that he produced above two hundred of these compositions, which were handed about in manuscript by the curious; but does not seem to know that nine or ten books of Tartini's solos were printed at Paris, of which we are in possession of opera third, sixth, seventh, and ninth, besides the two books printed in England, amounting to upwards of fifty solos, exclusive of manuscripts.

Of his concertos, which likewise amount to two hundred, this author gives a very unsatisfactory account; he says, that a surreptitious copy of two sets having first appeared in Holland, he would never own them. The first six seem to have been composed in his first manner before he changed his style. But Walther tells us, in 1732, that eighteen of his concertos for five instruments, principal violin, two ripieno violins, tenor, and violoncello, were published at Amsterdam. But Le Cene, the publisher, confessed, that he collected them from different people who had obtained copies from the author, and there seems not the least doubt of their being genuine.

Though Tartini's compositions always afforded us great pleasure, and were never obliterated from our memory; yet as they are now as much laid aside as those of Bassani or Locatelli, we thought it right to give them a revision before we ventured our sentiments concerning their merit.

Tartini, on a recent examination of his works, seems, to our conception and feelings, to have had a larger portion of genius and knowledge of composition as a mere instrumental composer,

composer, than any other author who flourished during the first fifty or sixty years of the last century. Though he made Corelli his model in the purity of his harmony, and simplicity of his modulation, he greatly surpassed that composer in the fertility and originality of his invention; not only in the subjects of his melodies, but in the truly cantabile manner of treating them. Many of his adagios want nothing but words to be excellent pathetic opera songs. His allegros are sometimes difficult; but the passages fairly belong to the instrument for which they were composed, and were suggested by his consummate knowledge of the finger-board, and powers of the bow. He certainly repeats his passages, and adheres to his original *motivo*, or theme, too much, for the favourite desultory style of the present times; but it must be allowed that by his delicate selection and arrangement of notes, his passages are always good; play them quick, or play them slow, they never seem unmeaning or fortuitous.

Indeed, as a harmonist, he was perhaps more truly scientific than any other composer of his time, in the clearness, character, and precision of his bases; which were never casual, or the effect of habit or auricular prejudice and expectation, but learned, judicious, and certain. Yet, with all our partiality for his style, talents, and abilities, as well as veneration for his principles and character, we must, in justice to others, own, that though the adagio and solo playing in general of his scholars were exquisitely polished and expressive, yet it seems as if that energy, fire, and freedom of bow, which modern symphonists and orchestra-playing require, were wanting. Perhaps the refinement of a Nardini and force of a Viotti are incompatible.

Since the time of Tartini, the productions of Boccherini, Haydn, Vanhal, Mozart, Pleyel, and others, have occasioned such a revolution in violin-music and playing, by the fertility and boldness of their invention, that compositions which were then generally thought full of spirit and fire, appear now totally tame and insipid.

This admirable musician and worthy man died the 26th of February, 1770, to the great regret of the inhabitants of the city of Padua, where he had resided nearly fifty years, and where he was not only regarded as its chief and most attractive ornament, but philosopher, saint, and sage. He had no children.

M. de Lalande says, he had from his own mouth the following singular anecdote, which shews to what degree his imagination was inflamed by the genius of composition. "He dreamed one night, in 1713, that he had made a compact with the devil, who promised to be at his service on all occasions; and during this vision every thing succeeded according to his mind; his wishes were prevented, and his desires always surpassed by the assistance of his new servant. In short, he imagined he gave the devil his violin, in order to discover what kind of a musician he was; when, to his great astonishment, he heard him play a solo so singularly beautiful, and executed with such superior taste and precision, that it surpassed all he had ever heard or conceived in his life. So great was his surprise, and so exquisite his delight upon this occasion, that it deprived him of the power of breathing. He awoke with the violence of this sensation, and instantly seized his fiddle, in hopes of expressing what he had just heard, but in vain; he, however, then composed a piece, which is perhaps the best of all his works, (he called it the Devil's Sonata,) but it was so inferior to what his sleep had produced, that he declared he should have broken his instrument and abandoned music for ever, if he could have substituted by any other means."

He was one of the few composers of his time, who con-

stantly drew from his own source; his melody was full of fire and fancy, and his harmony, though learned, yet simple and pure; and as a performer, his slow movements evince his taste and expression, and his lively ones his great hand. He was the first who knew and taught the power of the bow; and his knowledge of the finger-board is proved by a thousand beautiful passages, to which that alone could give birth. His scholar, Nardini, who played to us many of his best solos, as we thought, very well, with respect to correctness and expression, assured us that his dear and honoured master, as he constantly called him, was as much superior to himself in the performance of the same solos, both in the pathetic and brilliant parts, as he was to any one of his scholars.

Of his theoretical writings, we have had occasion to speak frequently and freely in former articles, particularly in our analysis of his SYSTEM, and Stillingfleet's Commentary. See STILLINGFLEET.

His practical works or compositions, always for his own instrument, the violin, consist of twelve solos on Corelli's model, six with double stops and fugues, with six of a lighter kind, in single stops, op. 1^a, six solos, op. 2^a, published by Walsh, about the year 1746, in a more free and original style. The first of this set, in E \flat , which was Brown's "Cheval de Bataille," appeared more than ten years at every concert at which he performed a solo in London. Two sets of concertos, in a very florid and difficult style, collected in MS. by travellers, and published in Holland by Le Cene and Witvogel without the author's permission, he called in, and cancelled the plates. However, we procured a copy from Holland, that was printed after the plates were scratched. We scored several of them, and found more beautiful passages, more difficulties and knowledge of the finger-board, than in any other violin solo concertos which we had ever seen. Many sets of beautiful solos were printed at Paris of his composition, which are wholly unknown in England. More than 200 of his violin concertos and solos were dispersed over the continent in MS.; many of his unedited solos we procured from his favourite disciple Nardini, at Florence, after his decease. If the concertos which he composed for his own performance in the church of St. Antonio de Padua could be procured, they would probably be in a grave and ecclesiastical style, peculiarly suitable to the place and piety of the author.

TARTON RAIRE, in *Botany*, a name used by some authors for the heath-spurge, or that species of the thymelæa which is called *fannamunda* in the catalogues of the *Materia Medica*.

TARTOOR, in *Geography*, a town of Hindoostan, in the circar of Cicacole; 9 miles S. of Visianagram.

TARTRATES, or TARTRITES, in *Chemistry*, salts formed by the combination of any base with the tartareous acid. These salts are numerous; as with some the acid forms two salts, differing in the proportions of the acid and base, and also as it is liable to form triple salts in which two bases are united with their respective portion of acid into one uniform compound. All the soluble alkaline and earthy tartrites, the latter being less soluble than the former, are decomposed by the salts of lead, and the acid of all is destroyed by calcination, leaving the base in the state of carbonate.

TARTRATE, *Super, of Potash*, is a combination of potash and tartareous acid in excess (whence its name), and to which it is owing that it has an acid taste, and that it reddens blue vegetable colours. This is the *cream of tartar*, or *tartarum acidulum*, the nature and manufacture of which have been described under the article TARTAR. (See also *Super-tartrate of potash* under SALTS.) This salt is not soluble without great difficulty, requiring about 30 parts of boiling water,

water, and at least 120, or as others say 60 parts of cold water; and hence a hot saturated solution begins to deposit crystals almost immediately after it begins to cool. So great is the affinity between the tartareous acid and that proportion of potash which constitutes the super-tartrate, that the acid of tartar will, partially or wholly, decompose all the neutral salts of potash, even the sulphate. Nevertheless, the affinity between the super-tartrate and the additional quantity of potash necessary for the complete saturation of this acid is much weaker than that of most other acids for potash; and hence arises a great number of decompositions, when tartareous acid, potash, and any other acid are mixed in different ways. The property, which the tartareous acid possesses, of decomposing the neutral salts with the basis of potash, is very useful in analysis, as it serves to distinguish them at once from the corresponding salts of soda and ammonia, which are not decomposable in the same manner. By saturating the excess of acid in cream of tartar with the several bases (potash excepted) various triple salts are produced. Although some inconvenience attends the use of borax in adding the solution of *Cream of TARTAR* in water (see that article); yet simple boracic acid has the power of rendering soluble four times its weight of cream of tartar in only five or six parts of hot water, and, as it is suggested, without decomposing the tartar, since the affinity of the boracic acid for the several bases is remarkably weak.

If a solution of cream of tartar in water is exposed to the air for a length of time, it gradually becomes turbid, a number of mucous flocculi are deposited, and in the course of some months it ceases to be acidulous, after which it becomes sensibly alkaline to the taste and to chemical tests, and it is finally converted into a weak solution of carbonate of potash, the tartareous acid totally disappearing, and carbonic acid taking its place. Fire operates a more rapid destruction of the tartareous acid, for if cream of tartar is calcined in an open fire with a red heat, it first softens, blackens, becomes of a pasty consistence, the acid burns off with flame and smoke, and finally a white carbonate of potash is left. The alkali procured in this way is very pure, and is often obtained for the laboratory by moistening crude tartar or cream of tartar to the consistence of stiff paste, wrapping up small parcels of it in brown paper, and arranging them in a grate or furnace of any kind with charcoal, and kindling it. After the charcoal has burnt out, the tartar is converted into lumps of carbonate of potash, which still cohere, and may be readily picked out of the ashes of the charcoal. A very pure carbonate of potash may also be made by deflagrating in a red-hot crucible equal parts of nitre and cream of tartar.

This salt is composed, according to Thenard, of 57 per cent. of tartareous acid, and 33 of potash, the remaining 10 parts being chiefly water of crystallization. Of these 57 parts of acid, 20 are in excess, so that the composition of the salt may be stated, in a different manner, to be 70 per cent. of tartrate of potash, and 20 of tartareous acid.

Cream of tartar is decomposed by lime and barytes, and probably by strontian, and caustic potash is left in the solution.

TARTRITE of Potash. See *Soluble TARTAR*, and *Tartrate of Potash* under *SALTS*. This salt, consisting of tartareous acid and potash in mutual saturation, is most conveniently prepared by adding cream of tartar to a hot solution of carbonate of potash. During the effervescence, the addition of cream of tartar should be continued; when this ceases, the solution should be boiled down till a pellicle appears on the surface, and then left to crystallize by cooling. The tartrate of potash then separates, generally in the form of pa-

rallelopipeds, with dihedral summits. When the salt is prepared in a large way for medicinal purposes, the evaporation is continued nearly to dryness, with frequent stirring, by which the salt is obtained in a shapeless granular mass. This salt is partially decomposed by the stronger acids. Tartareous acid dropped into a moderately strong solution of tartrate of potash causes an immediate deposit of cream of tartar. For other particulars, see the articles above cited.

TARTRITE of Potash and Soda, a triple crystallizable salt, prepared by throwing into boiling water about a fifth of its weight of cream of tartar, and adding gradually a quantity of carbonate of soda, whilst any effervescence is excited; then evaporating the whole to the consistence of syrup. As it cools, the triple salt will be obtained in large beautiful transparent crystals, generally of the form of eight-sided prisms, and often divided longitudinally through the axis. This salt, which is perfectly neutral, dissolves in about five parts of water, and somewhat effloresces by being exposed to the air. Barytes and lime totally decompose it, and the supernatant liquor contains a mixture of potash and soda. According to Vauquelin, it is composed of about 54 per cent. of tartrate of potash and 46 of tartrate of soda. It is decomposed by the stronger acids, and yields cream of tartar. See *RUPELLENSIS Sal*, and *SODA*.

TARTRITE of Potash and Ammonia, a triple salt prepared, in the same general manner as the preceding, by saturating cream of tartar with carbonate of ammonia, evaporating and cooling. Exposed to the air it effloresces, loses its ammonia, and returns to the state of simple cream of tartar.

TARTRITE of Potash and Lime, Barytes, &c. Between tartrate of potash and lime there exists a certain affinity, which tends to the formation of a triple salt, though lime will completely decompose any alkaline tartrate. Thus though simple tartrate of lime is insoluble in cold water, no precipitate is produced by the addition of a small quantity of lime-water into a cold solution of tartrate of potash, which must therefore be owing to the tartrate of lime, then formed, being rendered soluble by the remaining tartrate or rather subtartrate of potash. Even when cream of tartar is as completely as possible decomposed by lime in substance, in the process of obtaining the acid, the caustic alkaline liquor, supernatant over the precipitated tartrate of lime, still holds a small quantity of the latter in solution, as has been remarked by Vauquelin, which may be considered as a triple salt of tartareous acid, lime, and potash, the latter being in very large excess.

The same applies to barytes and strontian, the solutions of which do not immediately give a precipitate with tartrate of potash; and even if tartrate of barytes or of strontian recently formed and still wet be put into a solution of tartrate of potash, it is soon dissolved; though the mere quantity of liquid present would be entirely unable to effect a solution. There is therefore such a strong affinity between tartrate of potash and these earthy tartrates, as may perhaps entitle us to consider these compound solutions as triple salts, though they have not been obtained in a crystallized form like the triple tartrate of potash and soda.

Alumina unites with still greater ease with tartrate of potash: for when this earth, recently precipitated from alum by a caustic or carbonated alkali, and still wet, is transferred to a solution of tartrate of potash, it readily dissolves therein, and forms an uncrystallizable compound, which is not rendered turbid by any addition of potash or its carbonate. The Rochelle salt has the same habitude with alumina as the simple tartrate of potash, which therefore forms a quadruple compound of tartareous acid, potash, soda and alumina. See *ALUMINE*.

TARTRITE of Soda, a salt produced in small needled crystals from a due evaporation of tartareous acid saturated with soda. This salt, formerly confounded with the Rochelle salt, or *sal Rupellenfis*, is not very soluble in water; however, when tartrate of potash is added to this salt, each in saturated solution, large crystals of the triple tartrate, or Rochelle salt, are immediately deposited.

A *super-tartrate of soda* is formed by partially saturating tartareous acid with soda, and also by adding a strong acid to the saturated tartrate, which, being less soluble than the saturated compound, precipitates. It is observed, however, that tartareous acid will not form (visibly) an acidulous tartrate, when added to the sulphate and other salts of soda, as it will do with the salts of potash.

TARTRITE of Ammonia, a salt formed by saturating the tartareous acid with ammonia or its carbonate. This salt crystallizes readily, and is decomposed by the fixed alkalies and alkaline earths.

A *super-tartrate of ammonia* is formed in a similar manner to the super-tartrate of soda, and with the same exception of the acid not visibly decomposing the other ammoniacal salts. See **AMMONIA**, and *Tartrate of Ammonia* under **SALTS**.

TARTRITES, Earthy. See *Earthy SALTS*. See also *Tartrate of Lime* under **LIME**.

The *tartrate of lime* is produced in a white precipitate, by adding tartareous acid to any soluble salt of lime, or lime to a soluble tartareous salt. Although this salt is insoluble in mere water in a common temperature, it dissolves readily in an excess of its own, or of any other acid that does not decompose it, such as the acetic or muriatic. It is also rendered soluble in water by the addition of potash. When it is heated strongly in an open fire the whole acid is consumed, and carbonate of lime remains.

TARTRITES of Barytes and Strontiam, are formed in the same manner as tartrate of lime; but they are not so insoluble in water as this salt; and the tartrate of strontian will even crystallize from its hot-saturated solution by cooling. With *magnesia* and *alumine* this acid forms very soluble compounds, which do not crystallize by evaporation, but dry up into a gummy mass. Aikin's Dict.

TARTSCHIN, in *Geography*, a town of the duchy of Warfaw; 20 miles S.W. of Warfaw.

TARTURA, a town of Palestine, near the coast; 10 miles S. of Acre.

TARVA, a district of Arabia, on the banks of the Julfa.

TARUD, a town of Arabia, in the province of Hedjaz; 10 miles from El Catif.

TARUD Esberif, a town of Egypt, on the left bank of the Nile; 6 miles S. of Melauî.

TARUDA, in *Ancient Geography*, a town of Africa, in Mauritania Cæsariensis, near Ægea. Ptol.

TARUDANT, or **TARODANT**, in *Geography*, a town of Africa, and capital of the province, formerly kingdom, of Sufe, situated at the extremity of Morocco. The town is ancient and extensive, and is said to contain 25,000 inhabitants. It has a noble palace, to which belong gardens abounding with the most delicious fruits. Its population has lately decreased, and it is now famous only for saltpetre of a superior quality, for the manufacture of leather and saddles, and for dyeing. The town is watered by the river Sufe, which passes through it; and it is reported that ships formerly took in their cargoes at this place. It has sustained several sieges, and in the last, the inhabitants were reduced to the necessity of eating rats and burning their doors for fuel; 110 miles S.S.W. of Morocco. N. lat. 30° 20'. W. long. 8° 35'.

TARVES, a village in the district of Ellon, and shire of Aberdeen, Scotland, is situated on the banks of the river Ythan; 15 miles N. from Aberdeen, and 139 miles N. by E. from Edinburgh. The parish is about nine miles in length and six in breadth. The general appearance is flat, interspersed with some small hills; the soil is in some parts deep, and in others shallow; but mostly fertile. About a hundred acres are covered with thriving plantations. A general post-office is established here; and two fairs are holden annually. The public roads are in good repair. The parish church is ancient and ruinous. Here is a respectable parochial school, of which the salary is 300 marks, with school-fees and perquisites, and a rood of land. In the population return of the year 1811, Tarves was stated to contain 454 houses, occupied by 1804 persons.—Carlisle's Topographical Dictionary of Scotland, vol. ii. Gazetteer of Scotland, 8vo.

TARVIDUM, TARUEDUM, or *Orcas*, in *Ancient Geography*, a promontory on the southern coast of the isle of Albion, near the mouth of the river Nabau.

TARVIN, or **TARVEN**, in *Geography*, a township and parish in the hundred of Edisbury, and county palatine of Cheiter, England, is situated on the London road, five miles N. by E. from Chester. It had for some time a weekly market, procured by sir John Savage, in the reign of queen Elizabeth; but this has been long discontinued. An annual fair was also held here till within the last thirty years, but was then abolished. Tarvin was one of the parliamentary garrisons during the civil wars: in August 1644, it was a short time in the possession of the royalists; but in the following month it was retaken for the parliament, and fortified with strong works. This and Nantwich were the only garrisons in Cheshire not abandoned on the reported approach of the king, in May 1645; and the parliament retained it till the end of the war. A grammar-school was founded here in the year 1600. John Thomafen, a celebrated penman, was master of this school thirty-six years in the early part of the last century. On the outside of the parish church is an inscription to his memory, stating that he "highly excelled in all the varieties of writing, and wonderfully so in the Greek character. Specimens of his ingenuity are treasured up in the cabinets of the curious and in the public libraries throughout the kingdom." The township of Tarvin was stated in the population return of the year 1811, to contain 180 houses, occupied by 921 persons. The parish is very extensive, and includes 11 townships, containing in the whole 2877 inhabitants, the number of houses being 525.—Lysons' *Magna Britannia*, vol. ii. part 2, Cheshire. Beauties of England and Wales, vol. ii. Cheshire, by J. Britton and E. W. Brayley.

TARVISIUM, or **TARVISO**, in *Ancient Geography*, a town of Italy, towards the N.W. of Venetia.

TARUM, in *Botany*, a name given by Pliny to the *agalochum sylvestre*, a species of aromatic plants.

TARURAW, in *Geography*, a town of the state of Georgia; 14 miles N. of Tugeloo.

TARUS, or **TARO**, in *Ancient Geography*, a river of Gallia Cispadana, which ran towards the N.E., and E. of Trebia.

TARUSA, in *Geography*, a town of Russia, in the government of Kaluga, on the Oka. N. lat. 54° 52'. E. long. 36° 34'.

TARUSATES, in *Ancient Geography*, a people of Gallia Aquitania, mentioned by Cæsar in the 3d book of his Commentaries, who were compelled to submit by Crassus, Cæsar's lieutenant. Their city was named Vicus Julii and also Aturas.

TARUSCO, a town of Gallia Narbonnensis, near Glenum.

TARUSCONIENSES, a people of Gallia Narbonnensis, mentioned by Pliny, who occupied part of the territory of Tarascon on the Rhone.

TARWAS, in *Geography*, a town of Bengal; 28 miles E. of Nattore.

TASAGORA, in *Ancient Geography*, a town of Africa, in Mauritania Cæfariensis, on the route from Cula to Rufurum. Anton. Itin.

TASAPAN, in *Geography*, a small island in the East Indian sea, near Junkscilon. N. lat. 8° 20'. E. long. 98° 14'.

TASCA, **LUIGI**, in *Biography*, an opera singer with a powerful base, or rather baritone voice, who arrived in England in 1782, was a good musician, and not only a useful performer at the opera, but at the oratorio, and in the performances at Westminster Abbey in commemoration of Handel. His voice, however, wanted mellowness and flexibility: for like an oaken plant, though strong, it was stiff.

TASCHENMUL, in *Ornithology*, a name given by authors to the *anas clypeata*, a species of duck, remarkable for the breadth of the end of its beak, and called in English the *broveller*. See *Broad-beaked Duck*.

TASCHIEN, in *Geography*, a river of Bavaria, which runs into the Regen, 2 miles W. of Cham.

TASCHOW, a town of Bohemia, in the circle of Leitmeritz; 5 miles N. of Leitmeritz.

TASCIO, or **TASCIA**, in *Coinage*, is a term, which either wholly or in part, appears on many ancient British coins, and which has puzzled our antiquaries, who have formed several different opinions concerning it. Mr. Camden, Mr. Baxter, Dr. Pettingal, and others, have thought that this word is derived from *Tasck* or *Tascu*, signifying in the original language of Britain any land-burthen or tribute imposed by the Tag, or prince, and that all the money which had Tascia or any of its abbreviations upon it, had been coined for no other purpose but to pay the tribute which had been imposed on the Britons by Julius Cæsar, and the portaria or duties upon merchandize, which had been exacted by Augustus and his successors. Against this opinion, however, others have urged strong objections. The derivation of Tascio from Tag, a prince, by the intervention of Tascu, a burthen or task, it has been said, is far from being clear. Money coined for the sole purpose of paying tribute, is a thing, say the objectors, unknown in the history of mankind; nor is it probable that Cunobeline, who was a free and independent prince, the friend but not the subject of the Roman emperors, would have admitted a word of such ignominious import as Tascio is in this sense of it, upon his coins.

A modern author (see Wise Differt. in Numm. Bodl. Catal. p. 227.), dissatisfied with the above interpretation of the word Tascio, has proposed another. He supposes that Tascio is an abbreviation of some nation or people to whom this money belonged, and of which Cunobeline was king; and finding in Pliny (lib. iii. c. 4.) a people of Gallia Narbonnensis, called "Tascodunitari Conorienfes," in the MSS. "Tascoduni Taruconienfes," he conjectures, that Cunobelin Tascio may mean Cunobelin Tascodunorum. But this meaning is far-fetched, and depends upon improbable conjecture.

Another modern writer (see Pegge's Ess. on Cunobeline's Coins, p. 55.) has conjectured, that Tascio was the name of Cunobeline's mint-master, who struck all these coins. Although this opinion is more probable than the former, it is nevertheless strange, that this word, if it was a proper name,

should have been spelled by the person to whom it belonged in so many different ways, as Tascio, Tascia, and Tascie.

TASCO, in *Geography*, a town of Mexico, in the province of Mechoacan; 90 miles S.E. of Mechoacan. N. lat. 19° 5'. W. long. 101° 36'.

TASCONI, in *Ancient Geography*, a people of Gallia Narbonnensis, mentioned by Pliny, who occupied part of the diocese of Montauban. Their city bore the same name, and was situated N. of Tolose.

TASGOM, in *Geography*, a town of Hindoostan, in Vifia-pour; 10 miles N. of Merritch.

TASHAM DAGHI, a mountain of Asiatic Turkey, between Amafreh and Samsoun.

TASHKUND, **TASCHKUND**, or *Al Shafsb*, a town of Turkestan, on the Sir. This town has been often destroyed and rebuilt; 210 miles N. of Samarcand. N. lat. 42° 40'. E. long. 64° 48'.

TASHKUPRI, a town of Natolia; 14 miles S.E. of Castamena.

TASIEVA, a river of Russia, which runs into the Tchiuma, about 20 miles N.W. of Tafievskoi.

TASIEVSKOI, a town of Russia, in the government of Tobolsk, on the Tafieva; 820 miles E. of Tobolsk. N. lat. 57°. E. long. 94° 14'.

TASIO, a river of Sweden, which joins the Angermann at Liden.

TASIS, τασίς, in *Rhetoric*, is used for the continuation of a period longer than the breath can bear. Voff. Rhet. lib. iv. p. 66.

TAS-KUJE, in *Geography*, a town of Persia, in the province of Laristan; 84 miles N.E. of Lar.

TASLUI, a town of Moldavia; 20 miles S. of Niemez.—Also, a river of Moldavia, which runs into the Siret, near Adzud.

TASMAN'S HEAD, a cape on the coast of Van Diemen's Land. N. lat. 43° 33'. E. long. 147° 28'.

TASMANIA. See *Van Diemen's Land*.

TASOPIUM, in *Ancient Geography*, a town of India, on this side of the Ganges, near Caricardama, assigned by Ptolemy to the Sabaræ.

TAS-POULSASON, in *Geography*, a town of Chinese Tartary, in the country of Hami. N. lat. 40° 22'. E. long. 95° 54'.

TASPOUR, a town of Hindoostan, in Bahar; 27 miles E. of Hajypour. N. lat. 25° 52'. E. long. 85° 51'.

TASSA POINT, a cape on the coast of Guinea. N. lat. 8°. W. long. 12° 10'.

TASSA-CORTA, or **TASSA-CRODA**, a town on the W. coast of Palma, one of the Canary islands, which is an inconsiderable loading-place for vessels. N. lat. 28° 37'. W. long. 17° 58'.

TASSASUDON, **TASSISUDON**, or *Tassay-Seddein*, a town of Asia, and capital of the Bootan country, situated in a valley, computed to be about three miles in length, and one in breadth, lying N. and S., through which runs the river Tehintchieu. This valley is in a high state of cultivation, bearing various kinds of grain, and diversified by clusters of houses. The castle, or palace of Tassifudon, stands near the centre of the valley, and is a building of stone, of a quadrangular form; the walls are upwards of 30 feet high, sloped a little from the foundation to the top; above the middle space is a row of projecting balconies, to each of which are curtains made of black hair; which are always drawn at night; the walls are pierced below with small windows, for the admission of air rather than light; and there are two entrances to the palace: the one facing the south by

a flight of wooden steps, edged with plates of iron, and the other, which is the grand entrance on the east front, ascended by a flight of stone steps. Even with these is a spacious gateway, with two massy doors, fortified with knobs of iron, and secured when shut by a large bar of timber that slides within the masonry. Within is the central square building, which may be denominated the citadel, and which is the residence of the supreme Lama. It contains also the chief of their idols, Mahomoonie, amidst a multitude of others of inferior note. To the right and the left are avenues that lead to spacious squares, paved with flat stones, and to the apartments of the Lama. The citadel is seven stories high, each from fifteen to eighteen feet, and covered with a roof of low pitch, composed of fir timber; from the centre arises a square piece of masonry, supporting a canopy of copper, richly gilt, which is supposed to be directly over the great idol, Mahomoonie. The raja lives upon the fourth floor from the ground; above that are two other stories; and the seventh ladder reaches to the temple of Mahomoonie. The east, west, and south angles of the building correspond with each other, and have apartments on the ground floor appropriated for depositing all kinds of stores. A covered gallery runs all round them, beneath which are subterraneous places serving for kitchens. A range of good rooms, with boarded floors, on the first story, accommodates all the officers of state attendant on the raja, and those towards the square are skirted by a varande, supported by a row of handsome pillars, whose capitals are ornamented with carved work and gilding, and their sides painted with vermilion. Over this story is a sort of terrace of cement, with rooms more roughly finished for the inferior officers, called Zeenkerbs. For further particulars we refer to Turner's Embassy, in which is an engraving of the palace, and of the residence of Lama Glasse too in its vicinity. The road from Bengal to Tassafudon lies chiefly over the summits of stupendous mountains, or along the borders of craggy precipices: and between this city and Peridroog is a chain of mountains still higher than the other. These are visible from the plains of Bengal, at the distance of 150 miles, and are commonly covered with snow. They are a continuation of the mountains Emodus and Paropamisus of the ancients; 206 miles S.W. of Lassa. N. lat. 27° 48'. E. long. 89° 12'.

TASSEL, a sort of pendent ornament, at the corners of a cushion, or the like thing.—Also, a small ribband of silk sewed to a book, to be put between the leaves.

TASSELS, in a *Building*, those pieces of board that lie under the ends of the mantle-trees.

TASSEL, or *Tiercelet*, is also used in *Falconry* for a male hawk.

TASSELS are also a kind of hard burrs used by cloth-workers in dressing of cloth; they are the heads of the manured teasel.

TASSES, or **TASSETS**, in *Ancient Armoury*, appendages to the corselet, consisting of skirts of iron that covered the thighs, and that were fastened to the cuirass with hooks.

TASSI, **AGOSTINO**, in *Biography*, the cognomen of an artist whose real name was Buonamici. He was born at Perugia in 1566, and studied at Rome under Paul Brill, and received some assistance in the school of the Carracci. His loose and irregular conduct procured a seat for him on the bench of a gallery at Leghorn; and there, though under confinement and disgrace, he occupied his leisure in painting views of the objects with which he was surrounded; and when he obtained his liberty, such subjects became the favourite occupation of his pencil. His sea-ports, calms, and storms, were faithful transcripts of nature, and touched with great spirit and effi-

cacy. His views of architectural subjects thrown into perspective, which are in the pontifical palace of Monte Cavallo, and in that of the Lancellotti family, are admirable in their kind. His greatest honour, however, is having been the instructor of Claude de Lorraine. He died in 1642, aged 76.

TASSING, in *Geography*. See **TASSINGE**.

TASSO, **BERNARDO**, in *Biography*, an eminent poet, born at Bergamo of an ancient and noble family in the year 1493, became an early proficient in the Greek and Latin classics. His uncle, the bishop of Recanati, who was his instructor and patron, and supplied the place of a parent when he lost his father, having been assassinated by robbers in 1520, Bernardo was under a necessity of quitting his native city, and in 1525 became secretary to count Guido Rangoni, general of the papal army. Having been for a short time occupied in a similar situation under the dukes of Ferrara, he afterwards pursued his studies at Padua and Venice. In 1531 he published at Venice a volume of poems, which induced Ferrante Sanseverino, prince of Salerno, to invite him to his court. Having accepted this invitation, he recommended himself to the prince, and obtained annual stipends, amounting to 900 ducats. He accompanied his patron in several expeditions, and accompanying him to Naples, he there married Porzia de' Rossi, a lady of noble family. At Sorrento, whither he removed, he for some time led a tranquil and studious life; until his patron, in 1547, incurred the displeasure of the imperial court by concurring in presenting a petition against the establishment of the inquisition at Naples. On this occasion the prince joined the French party, so that he was declared a rebel, and his property was confiscated. Influenced by respect for his patron, Bernardo accompanied him to France, where at first he obtained encouragement, but being in process of time deprived of all support, and having lost his wife, he requested the prince's permission to leave him; and complying with an invitation to the court of Guidobaldo II., duke of Urbino, a distinguished patron of literary persons, he was liberally compensated for his past sufferings, and made a member of the celebrated Venetian academy. In 1563 he became secretary at the court of Mantua, and in the service of this court he died in 1569, being then governor of Ostiglia. The duke of Mantua caused his remains to be honourably interred in that city, and a marble monument to be erected over his tomb, bearing the simple inscription, "Ossa Bernardi Tassi." Of his poems, belonging to the class of "Romanesque," there were two; viz. "Amadigi," consisting of 100 cantos, and "Il Floridante," left unfinished, but corrected and published by his son Torquato, at Bologna, in 1587. His other works are five books of "Rime," with various kinds of poems, such as eclogues, elegies, hymns, odes, &c. He was also the author of "A Discourse concerning Poetry," and "Letters," of which an edition has been given in three volumes.

TASSO, **TORQUATO**, pre-eminent as an Italian poet, was the son of Bernardo and Porzia de Rossi, born at Sorrento March 11, 1544, and sent at the age of five years to the Jesuits' school at Naples. Here his proficiency was so rapid, that in two years he recited, publicly, verses and orations of his own composition. At Bergamo, whither the circumstances of his family constrained him to remove, he prosecuted the study of Latin and Greek with such success, that at the age of twelve years, he was admitted into the university of Padua. Here his proficiency in various branches of literature was so signal, that in his seventeenth year he was honoured with degrees in the four branches of canon and civil law, theology, and philosophy. For law he had no predi-

predilection; but all the powers and affections of his mind were devoted to poetry. Thus distinguished, he was invited by the celebrated Cetti to Bologna, in the schools and academies of which city his talents were eminently displayed. During his residence in Bologna, he was charged with having written some defamatory verses, and deprived of his books; and though he avowed his innocence, he thought proper to withdraw from the city to a place called Castlevetro, where he was protected by the count Rangoni. Some time after this event he settled at Padua, and acquired distinction among the academicians denominated "Eterei." At the age of eighteen years he had published at Venice his poem of the Romanesque class, entitled "Il Rinaldo," which he dedicated to cardinal Luigi d'Este, in consequence of which he was invited, in 1566, to the court of Ferrara, where he was liberally accommodated, and where, it is said, he prosecuted the execution of his plan of the "Gerusalemme Liberata;" six cantos of which were composed in the 17th year of his life. In 1571 he accompanied the cardinal d'Este into France, where he was honourably received by Charles IX. and his court, and also by all the learned men of Paris. In the following year he returned to Italy, and caused to be represented his dramatic pastoral of "Aminta." Several cantos of his "Gerusalemme" were at this time dispersed in MS. throughout Italy, and in 1579 the fourth canto was printed in a collection of poems at Genoa. In the following year, fragments of 16 cantos were published at Venice, and we may naturally imagine that this mode of introducing to public notice a work on which he had bestowed much attention and labour, excited his displeasure. In 1581 three editions were printed, and of these, the third at Ferrara has been considered as that which first exhibited this celebrated work in its genuine form. It has occasioned some degree of surprise, that Tasso himself did not guard against these incorrect publications, by committing his work to the press in a more perfect state. His negligence in this respect has been attributed to some mental malady under which he laboured. Of the cause of this malady different accounts have been given. Tiraboschi has narrated a variety of circumstances, which operating on a mind like that of Tasso, might have contributed to produce, or at least to aggravate the mental disorder under which he laboured. His narration is recited in the General Biography; but within our limits we cannot do it full justice. His first provocation seems to have been excited by a courtier, who divulged the secret of his amours, in the presence-chamber of Alfonso, duke of Ferrara, and whom he publicly insulted, so that he was under a necessity of defending himself with his sword against the aggressor and his three brothers. The brothers were banished, and Tasso was confined to his apartment. Disturbed in his mind, and dreading worse consequences, he made his escape, wandered to Turin, Rome and Sorrento, and at length obtained permission to return to Ferrara. Suspecting some hostile design, he withdrew to the court of Urbino, and again returned to Ferrara. Here his disorder was so manifest, that Alfonso ordered him to be shut up in a hospital appropriated to lunatics. The evidence of his disorder is said by some to have been an indecorous liberty which he took in saluting the princess Leonora, the duke's sister; but others have thought this circumstance very improbable, and indeed it is hardly necessary to make an attempt for justifying the duke's conduct in the confinement of Tasso, after he had given so many incontestible proofs of mental derangement. At length, however, Tasso was restored to entire liberty. But his disposition to wander still continued; and it is lamentable to reflect, that, as one of his biographers observes, "the admired author of 'Jerusalem delivered,' the favourite of princes and the boast

of Italy, should have harboured in his mind something which defeated every plan to render his circumstances prosperous." His last retreat was with cardinal Cinzio Aldobrandini, at Rome, who obtained for him a pension from pope Clement VIII., and had intended, as a compensation for his sufferings, to procure for him the honour of a solemn poetical coronation in the Capitol; but the ceremony was delayed on account of the cardinal's illness, and Tasso manifested symptoms of approaching dissolution. As soon as he was apprized of his danger, he was removed to the convent of St. Onofrio, where, deriving every possible consolation from the kindness of the cardinal, and exhibiting every evidence of sincere piety, he closed his days in April 1595, at the age of 51. His remains were honourably interred, and after some time a monument was erected to his memory by cardinal Bonifacio Bevilacqua, in the church of St. Onofrio. Tasso, "in person, was tall, active, and well-proportioned, naturally of a firm temperament, and fit for all bodily exercises. He was sparing of words, sedate and grave in manner, and in conversation displayed little of the fire that animates his works. He was kind and affectionate in all his social relations, and conducted himself with great propriety in company."

His works are very numerous. Those in prose consist of a great number of treatises, dialogues, and letters, on moral, literary, and familiar topics. In poetry, his "Gerusalemme Liberata" is pre-eminent. "Its subject is singularly happy, its characters well-drawn and supported, its fictions strongly imagined, its style dignified, and its versification harmonious." His "Gerusalemme Conquistata," published in 1593, was a kind of recomposition of the former work, but less satisfactory to its readers. His "Aminta" has been already mentioned; his "Rime" consisted of occasional and miscellaneous pieces; his "Sella Giornata," or Works of the Seven Days, pieces on sacred topics, bear the impression of the gloomy state of his mind. Tiraboschi. Gen. Biog.

TASSO, in *Geography*, a small island on the W. coast of Africa, at the mouth of the river Sierra Leona.

TASSO, or *Thaso*, an island of the Grecian Archipelago, situated in the gulf of Contesa, towards the W. extremity of Macedonia, and two leagues from the continent. The channel which separates that island from the main land is also divided by a sterile inlet called "Little Tasso," and in Greek "Tasso-poulo," the vestige of an ancient continuity of lands, at present separated. A spacious road, where the ground is good for holding, lies between the two islands. Tasso is the most northern of the islands of the Archipelago, and its high mountains, covered with forests, are seen at a distance. This island was formerly one of the most famous for its rich gold mines. Herodotus speaks of them, and they were under the direction of Thucydides. These mines led the Greeks to denominate it Chryse, signifying gold or gilt; its riches had become proverbial, and the expression was a "Thasos of wealth." Its natural treasures also were opals, amethysts, and other precious stones; but though these are lost, Tasso still furnishes the beautiful marble, that forms the greater part of the mountains, which was anciently held in such estimation by the Romans; the whiteness of which vies with snow, and the fineness of its grain with that of Parian marble. The inhabitants of Paros are said to have peopled the island of Tasso, and to have there built the town of Thasos, which was its capital, and the vestiges of which are still to be seen. The island is near 30 leagues in circumference; it produces abundance of corn, oil, wax, &c.; but the fertility, extolled by the ancients, is turned to no account for want of encouragement and culture.

ture. Its wines, famous even in the time of the Lower empire, as Chrysolom exclaimed against the excesses to which they gave rise at Constantinople, have no longer the excellent qualities which caused them to fetch a high price. Its population has experienced the same fate as the productions of its soil; it is considerably diminished. Tasso, however, has still remaining a kind of wealth very important to a maritime and trading nation; this is capital wood for ship-building. N. lat. 40° 34'. E. long. 24° 46'.

TASSONI, ALESSANDRO, in *Biography*, an Italian poet and man of letters, was born of an ancient and noble family, at Modena, in the year 1565. Notwithstanding various disadvantages in early life, such as the loss of his parents, a feeble diseased frame, and the persecution of enemies, he successfully cultivated Greek and Latin literature, poetry, and eloquence. At the age of twenty he sought further improvement in the university of Bologna, and here, as well as at Ferrara, he directed his particular attention to jurisprudence. Being under a necessity of seeking employment, he went to Rome, where, being known by his writings, he was admitted into the service of cardinal Colonne, as secretary, and accompanied him to Spain in the year 1600. Being afterwards domesticated with cardinal Cesi, he became a member of the academies degli Umoristi and de' Lincci, and was held in high estimation among the literati of Rome. A specimen of his "Pensieri diversi" (Thoughts on various Subjects) was published in 1608, under the title of "Questi," and the whole in 1612. His "Considerations on Petrarch" were first printed in 1609, and were intended to restrain the prevalent idolatry of this author. In 1613 he entered into the service of Charles Emanuel, duke of Savoy, in which situation he was regarded as an enemy to the Spanish monarchy; and he was considered as the author of "Philippics" against the Spaniards, and of a book entitled "Essequie della Monarchia di Spagna." In 1623 he quitted the family of Savoy; and about this time he finished "A Compendium of the Annals of Baronius." In 1626 he was taken into the service of cardinal Lodovico, nephew of Gregory XV.; and upon his death, in 1632, he was invited to the court of Francis I., duke of Modena, who gave him a pension and some honorary titles. Of this situation death deprived him in 1635, at the age of 70. One of his biographers says of him, that "he had a prepossessing countenance, with a cheerful expression, was open in conversation, a good speaker, serious or pleasant, according to the occasion, of a lively imagination, and sound judgment." The work by which the memory of Tassoni is chiefly preserved is his mock heroic poem "La Secchia Rapita." Tiraboschi. Gen. Biog.

This penetrating and learned writer, in the tenth book of his "Pensieri diversi," treats of music, ancient and modern, but not with his usual acumen or severity. He only retails the old stories of its miraculous powers among the ancients, and tries to match them by wonders pretended to be performed by its inferior perfections in modern times, without any remarks or reflections which discover a knowledge of the art, or doubts of the authenticity of these relations.

After speaking of extraordinary dilettante composers of music in modern times, he says, "among these we may enumerate James I., king of Scotland, who not only composed sacred music, but invented a new species of plaintive melody, different from all others; in which he has been imitated by the prince of Venosa, who, in our times, has embellished music with many admirable inventions."

This passage has given birth to two capital mistakes, into which the readers and writers of musical history have been led, particularly in Scotland. In the first place, it in-

sinuates that James I. was the inventor of the national melodies of that country; and secondly, that these melodies had been imitated in Italy by the prince of Venosa, a voluminous and celebrated dilettante composer of madrigals in the sixteenth century.

Unluckily for the favourers of these opinions, the Scots' national melodies can be proved of much higher antiquity, not only than David Rizzio, but the time of James I. See RIZZIO, JAMES I. of Scotland, and OSSIAN.

And the prince of Venosa, who was not the great musician he was reported to be by learned men who were ignorant of music, has not in all his works, which we have carefully examined, a single passage of melody which reminds us of the national tunes of Scotland; the melodies of which resemble those of no other country with which we are acquainted, except those of China. See VENOSA, and CHINESE Music.

Another Alessandro Tassoni of Modena, born in 1488, made a compilation of the different annals of that city, published in Muratori's Collection of Italian historians.

TASSOV, in *Geography*, a town of Moravia, in the circle of Iglau; 30 miles S.E. of Iglau.

TASSU, a town of Persia, in the province of Adirbeitzan; 60 miles W. of Tauris.

TASTATURA, Ital., the whole range or set of keys, in an organ, harpsichord, virginal, spinet, clavichord, or piano-forte. The term is naturally formed from *taſto*, a touch, or key. The Italians, we believe, call the finger-board of the lute, guitar, viols, and all stringed instruments with a neck that is fretted, the *taſtatura*.

TASTE, SAVOUR, a sensation excited in the soul by means of the organ of taste, viz. the papillæ of the tongue, &c.

Dr. Grew, in a lecture on the diversity of tastes, before the Royal Society, distinguishes them into *simple* and *compound*. By *simple* tastes he understands such as are simple modes of taste, although mingled with others in the same thing: thus, the taste of a pippin is aci-dulcis; of rhubarb, amar-altringent, and therefore compounded, in both; but yet in the pippin the acid is one simple taste, and the sweet another, as distinct as the bitter and altringent are in the rhubarb.

Two faults, he observes, have here been committed: the first, a defective enumeration of simple tastes; the second, a reckoning of them indistinctly among such as are compounded.

Simple tastes, of which we usually only reckon six or seven sorts, are at least sixteen: 1. *Bitter*, as in wormwood; whose contrary is, 2. *Sweet*, as in sugar. 3. *Sour*, as in vinegar; whose contrary is, 4. *Salt*. 5. *Hot*, as in cloves; to which is opposed, 6. *Cold*, as in sal prunellæ; for we may as properly say a cold taste as an hot one, since there are some bodies which do manifestly impress the sense of cold upon the tongue, though not to the touch. 7. *Aromatic*; to which is contrary, 8. *Nauseous*, or malignant. 9. *Soft*, which are either vapid, as in water, starch, whites of eggs, &c. or unctuous, as in oils, fat, &c. 10. *Hard*, of which he reckons four kinds. 11. *Penetrant*, which worketh itself into the tongue without any pungency; as is found in the root and leaves of the wild cucumber. 12. *Stupefacient*, as in the root of black hellebore, which, being chewed, and for some time retained upon the tongue, affects that organ with a numbness, or paralytic stupor. 13. *Astringent*, as in galls. And, 14. *Pungent*, as in spirit of sal armoniac; which two last tastes he makes contrary to the unctuous, as penetrant and stupefacient are contrary to the vapid one.

TASTE.

The *compound* tastes are very numerous; but we have words to express but six of them: 1. *Austere*, which is astringent and bitter, as in the green and soft stones of grapes. 2. *Acerb*, properly so called, which is astringent and acid, as in the juice of unripe grapes. 3. *Acrid*, which is pungent and hot. 4. *Muriatic*, which is salt and pungent, as in common salt. *Lixivious*, which is saltness joined with some pungency and heat. 6. *Nitrous*, which is saltness joined with pungency and cold.

Taste constitutes one of the most obvious characters of bodies, and much is to be judged from it of the nature of many things. Dr. Abercromby, in a treatise partly written on this subject, has carried his observations so far, as to lay down a set of rules for the judging of any plant, or other body, without knowing what it is, merely from its taste, in regard to its virtues in medicine.

In order to judge of what he expressly means by the names of the several tastes, it is proper to add the list of them, with some of the things to which they are applied.

Plants, fruits, &c. are either four as the common sorrel, harsh as the medlar, austere or rough as the quince, sweet as the fresh juice of ripe grapes, fat and oily as the sesamum, bitter as gentian or the wild cucumber, salt as common sea-salt, tart as garlic, or, lastly, insipid as the gourd, or of some mixed tastes, made of two or more of these.

The harsh or acerb things are cold, repelling, and binding, hardly concocted, and they may all be known upon the tongue by their contracting or drying it. The austere or rough things differ from these only in degree, as being somewhat milder in taste, and weaker in virtues.

The four or acid things are always cooling; but this never to excess, by reason of their penetrating parts: this taste is known by a biting on the tongue, but without any heat. Sweet things are all nutritive; and taking the word in its proper sense, they only have this quality. Their sweetness arises from their neither being too hot nor too cold upon the tongue.

Fat things are moderately hot, and, on this account they all, in some degree, moisten and relax; but they also obstruct: they are known from the sweet things by filling, and, as it were, anointing the tongue, without giving that sense of pleasure that the others do.

Salt things are astringent and deterfive; the one quality they have from their earthy part, the other from their watery.

Bitter things may be very beneficial to the stomach; but, in improper cases, they may also do hurt. The pungent bitters, such as the elaterium, or wild cucumber, are all hurtful, unless rendered safe by other means.

Tart things are hot, and often bad for the head, but good in heavy and phlegmatic constitutions: they are known by their heat in the mouth.

Lastly: insipid things in general have no peculiar quality, but are cold and watery; they are generally hurtful to the stomach, unless mixed with hotter and spicy things. Abercromb. Nov. Medic. Clavis.

It is observed by sir John Floyer, that the taste is so good a judge for us, that all the chemical principles in plants may be discovered by it, before their distillation. All watery plants shew their phlegm, as well to the taste as by distilling; and in all dry woods, the taste discovers the earth they contain, as well as a chemical analysis; by the mucilaginous and gummy taste, and by the manifest oiliness in some plants, we distinguish their abounding in oil as well as by the retort. The smell also helps us greatly in an extemporary judging of plants, and we are able to declare upon the spot, that all the aromatic plants, and all the fetid ones, contain a large

quantity of a volatile oil and salt. By the acrimony and pungency, we are well assured that there is a volatile salt in plants; and by the burning taste of others, we find that there is a corrosive salt in them. By a crude rough acidity, we distinguish the tartar or essential salt of plants to be in large quantity; but if the acidity be of a vinous smell, we observe that it is of a middle state of digestion, and may be called a vinous tartar, and distinguished from the first; but if the tartar have a pungent smell, then it is evidently a volatile tartar, or an acid acid tartar.

The sweet tastes are more numerous in plants, and more varied among themselves than any other kind. These, in general, shew their oil by thin slimy smoothness, and their tartar is evident in their extracts, as is very plain in the common liquorice-juice.

The graft-sweets, as the common dogs-graft, and the like, have much essential salt, and a moderate portion of oil; and the rush, reed, horse-tail, and cats-tail, are all sweet and rough; some of these have more oil, and others more acid; and the most crude among them have more oil than tartar. The corn-sweets, as barley, rye, wheat, oats, millet, and rice, have much oil and essential salt, and a little volatile; so bread, prepared of any of these, yields, on analysis, oil and essential and volatile salt.

It is to be observed here, that fermentation and fire severally produce a volatile salt, where it was not before, by subtilizing and volatilizing the essential salt; and the slimy mealiness in corn supplies the oil. The goats-beard and scorzonera-kind have the same principles as the grasses, much oil and essential salt. The sub-acrid sweets, as rampions, campanulas, trachelia, and the like, contain much oil and essential salt; but the acrimony in these plants shews that they have also a volatile salt, and that in no small quantity; though Lemery, and the other chemical writers, have not observed this.

The ferns, polypodies, and all that class of plants, contain much oil and essential salt; but the chemists in general have omitted to mention an acrid principle in all these, which bespeaks a volatile salt; and fragrantcy is observed in some of the harts-tongues, which bespeaks a volatile salt also, and volatile oil, though hitherto unobserved.

All the leguminous slimy sweets have more oil than tartar; but all of them have a large quantity of both. Beans, peas, and lentils, have also a volatile salt, as has also that strange fruit, eaten in Russia, and some other places, and called *lenticula aquatica* by some; but by the botanical writers, *tribulus aquaticus*; the other name belonging to the common duck-weed. The aromatic legumens, such as melilot, have an exalted oil, and volatile salt. The honey-suckle is said by Lemery, and the other chemists, only to have an essential salt and oil; but as there is a highly aromatic flavour, and great acrimony, there must be also a volatile salt.

These are some few instances, out of a vast number recited by the author, for the rest of which we refer to the paper itself in N^o 280 of the Transactions. Philos. Trans. N^o 299, p. 1160. See TASTING.

TASTE is also used, in a figurative sense, for the judgment and discernment of the mind.

We talk, and we hear every day of taste, of good taste, and of bad taste, and yet without well understanding what we mean by the word: in effect, a good taste seems to be little else but right reason, which we otherwise express by the word judgment.

To have a taste, is to give things their real value, to be touched with the good, to be shocked with the ill; not to be dazzled with false appearances; but, in spite of all colours,

lours, and of every thing that might deceive or amuse, to judge soundly.

Taste and judgment then should be the same thing; and yet it is easy to discern a difference: the judgment forms its opinions from reflection; the reason, on this occasion, takes a kind of circuit to arrive at its end; it supposes principles, it draws consequences, and it judges; but not without a thorough knowledge of the case: so that after it has pronounced, it is ready to render a reason of its decrees. Taste observes none of these formalities; before it has time to consult, it has taken its resolution: as soon as ever an object is presented to it, the impression is made, and the sentiment formed; and we ask no more of it. As the ear is wounded with an harsh sound, as the smell is soothed with an agreeable odour, before ever the reason has meddled with those objects, to judge of them; so the taste is struck at once, and prevents all reflection.

Reflections may come afterwards to confirm this taste, and discover the secret reasonings of its conduct; but it was not in its power to wait for them. Frequently, it happens not to know them at all; and what pains soever we use, we cannot discover what it was that determined it to think as it did.

This conduct is very different from that which the judgment observes in its decisions; unless we choose to say, that good taste is, as it were, a first motion, or a kind of instinct of right reason, which hurries us on with rapidity, and conducts us more securely than all the reasonings we could use. It is a first glance of thought, which discovers to us the nature and relation of things, as it were, by intuition.

In effect, taste and judgment are one and the same thing, one and the same disposition and habitude of the soul, which we call by different names, according to the different manners in which it acts: when it acts by sensation, by the first impression of objects, we call it taste; and when by reasoning, after having examined the thing by all the rules of art, &c. we call it judgment: so that one may say, taste is the judgment of nature, and judgment is the taste of reason.

Good taste, as defined by Madem. Scudery and Madem. Dacier, in an express treatise "Of the Corruption of Taste," is an harmony between the mind and reason; and a person has more or less of this taste, as that harmony is more or less just.

One might, perhaps, improve on this hint, and say, that good taste is nothing else but a certain ratio or relation between the mind, and the objects presented to it. Right reason cannot but be moved and affected with things conformably to it, and wounded by those contrary: there is, then, a kind of sympathy, which unites them as soon as ever they meet; and at their union, their good understandings discover each other.—Make a fine discourse; use only the richest and noblest expressions; if they contain an unhappy thought, or an incoherent reasoning, that thought, this reasoning, will immediately be felt by a person of taste: and the antipathy will shew itself by a movement of aversion, as sudden, as lively, and as natural, as that which nature inspires us withal for toads or spiders.

The term *taste*, used generally, is equivocal, and is used in at least three distinct acceptations. It sometimes means that peculiar mode of sensation, which resides in the tongue and palate; sometimes, the power of discrimination in the fine arts, or the feeling associated with it; sometimes, in a sense derived from the latter, it means liking or opinion in general.

It has been a subject of much controversy, whether taste, in the second sense, as we use the term in this article, be a distinct faculty, or merely a mode of judgment. The fact

seems to be, says an anonymous writer, that pleasurable emotions are excited by certain objects or conceptions, and that, when we embody our feelings in words, we use expressions of comparison, and reference to a standard, as in other propositions. Feeling and judgment therefore concur; but to which the word *taste* should be peculiarly applied, it is not easy to determine. The primary sense of the word, and of its equivalents in modern languages, seems to imply the former, as the word *criticism* manifestly refers to the latter meaning.

Dr. Gerard, in his ingenious and elaborate "Essay on Taste," observes, that a fine taste is neither wholly the gift of nature, nor wholly the effect of art. It derives its origin from certain powers natural to the human mind, but these must be assisted by culture, in order to attain their full perfection. Taste, according to this writer, consists chiefly in the improvement of those principles, which are commonly called the powers of imagination, and are considered by modern philosophers as internal or reflex senses, supplying us with finer and more delicate perceptions, than any which can be properly referred to our external organs. The simple principles of taste are the senses of novelty, of sublimity, of beauty, of imitation, of harmony, of ridicule, and of virtue. Any one of the internal senses, existing in vigour and perfection, forms a particular branch of taste, and enables a man to judge in some one subject of art or genius; but all of them must at once be vigorous, in order to constitute taste in its just extent. Taste will also derive considerable assistance from another principle, distinct from all the internal senses; and this is such a sensibility of heart or delicacy of passion, as fits a man for being easily moved, and for readily catching, as by infection, any passion that a work is fitted to excite, to which we might add the influence of casual associations on taste. Moreover, the most complete union of the internal senses is not of itself sufficient to form good taste, even though they be attended with the greatest delicacy of passion. They must be aided with judgment, the faculty which distinguishes things different, separates truth from falsehood, and compares together objects and their qualities.—Good sense is an indispensable ingredient in true taste, which always implies a quick and accurate perception of things as they really are; and, as the poet observes,

"Is, though no science, fairly worth the seven."

Taste, like every other human excellence, is progressive and improveable: and goodness of taste lies in its maturity and perfection; consisting, as Dr. Gerard says, in certain excellencies of our original powers of judgment and imagination combined. These may be reduced to four, *viz.* sensibility, refinement, correctness, and the proportion or comparative adjustment of its separate principles. All these must be in a considerable degree united, in order to form true taste. And this excellence of taste supposes not only culture, but culture judiciously applied. Want of taste unavoidably springs from negligence; false taste from injudicious cultivation. Sensibility of taste, we are told, depends very much on the original construction of the mind, and is less improveable by use than any other of the qualities of good taste. Refinement or elegance of taste is chiefly owing to the acquisition of knowledge, and the improvement of judgment. Refinement of taste exists only, where to an original delicacy of imagination, and natural acuteness of judgment, is superadded a long and intimate acquaintance with the best performances of every kind. And as sensibility of taste disposes us to be strongly affected with whatever beauties or faults we perceive; and refinement of taste

makes

TASTE.

makes us capable of discovering both, even when they are not obvious; so correctness of taste prevents our being imposed upon by false appearances, and either approving shining faults, or condemning chaste virtues, and enables us to assign to every quality its due proportion of merit or demerit: thus distinguishing the various kinds, and measuring the different degrees of excellence and faultiness. The last finishing and complete improvement of taste, result from the due proportion of its several principles, and the regular adjustment of all its sentiments, according to their genuine value, so that none of them may engross our minds, and render us insensible to the rest. This due proportion of the principles of taste pre-supposes the correctness of each, and includes, besides, an enlargement and comprehension of mind. Dr. Gerard has also considered, how far taste depends on the imagination, evinced the connection of taste with genius, and the influence of taste on criticism, illustrated the objects and the pleasures of taste, and traced the effects of taste on the character and passions.

“ Ingenuas didicisse fideliter artes,
Emollit mores, nec finit esse feros.”

Nothing is so improving, says Hume on the subject of delicacy of taste, to the temper, as the study of the beauties either of poetry, eloquence, music, or painting. They give a certain elegance of sentiment to which the rest of mankind are utter strangers. The emotions which they excite are soft and tender. They draw off the mind from the hurry of business and interest; cherish reflection; dispose to tranquillity; and produce an agreeable melancholy, which, of all dispositions of the mind, is the best suited to love and friendship. Besides, a delicacy of taste is favourable to love and friendship, by confining our choice to few people, and making us indifferent to the company and conversation of the greater part of mankind.

Taste, says Gerard, may be conceived as employing itself about nature, art, and science. With regard to nature, which is the common subject of the other two, taste and reason are employed in conjunction: as reason investigates the laws of nature, taste alone discovers its beauties. In art, taste is the ultimate judge, and reason but its minister. Scarcely any art is so mean, or so entirely mechanical, as not to afford subjects of taste. But the finer arts, which imitate the excellencies of nature, supply it with more proper materials; and thence derive their merit. Music, painting, statuary, architecture, poetry, and eloquence, (to which may be added gardening, including the art of improving grounds, and the stage,) constitute its peculiar and domestic territory, in which its authority is absolutely supreme. In science, reason is supreme, but may sometimes reap advantage from using taste as an auxiliary which serves to judge, not only of the manner in which science is communicated, but also of the subject-matter itself.

To this essay of Dr. Gerard are annexed three dissertations on the same subject; one by Voltaire; another by M. D'Alembert, read before the French academy in 1757, and intended to shew the great advantages of philosophy in its application to matters of taste, and to justify it from the accusations that have been brought against it by ignorance and envy; and the third is a fragment of Montesquieu.

We observe, that the arts above enumerated, are distinguished from those that are merely mechanical, as well as from the speculative sciences, by this circumstance; that their main end is neither utility, in the common sense of the word, nor instruction; but to minister to the pleasures of the imagination, by means of words, or of sensible images, or of

both of these combined. But their most eminent characteristic, perhaps, which runs through all of them, is, that many of their principles, though in one sense founded upon nature, since their only object is to delight the imagination of men, are not derived from ordinary nature; but require a good deal of attention, and the formation of habits, before they can be relished or understood. When we say, that these eight arts are the proper objects of taste, we do not intimate that their principles are altogether in common; or that he who is thoroughly acquainted, e. g. with the theory of painting, will be necessarily a good judge of poetry or architecture; since all of them have many rules originally arbitrary, the accurate knowledge of which has become indispensable to the man of taste; and which, in many cases, suggest pleasures to the imagination, not inferior to those which appear more directly natural. Nevertheless, a man who has applied the accuracy of discrimination, delicacy of feeling, and habitual reference to an original standard, in which the exercise of taste consists, to any one of those arts, can hardly fail, by sufficient attention and experience, to become a judge of all the rest. This observation, however, is liable to some exceptions, particularly in reference to music, which no one whose ear is naturally imperfect, will ever be able to understand. After all it must be allowed by those who maintain the necessity of admitting principles and a standard of taste, that a prodigious difference will be found to remain in the sentiments of mankind, with regard to matters of taste; and this diversity of sentiment in judging concerning the productions of art, may be ascribed to three causes; viz. want of feeling, or inability to enjoy, in any great degree, the pleasures of the imagination, as in the instance to which we have above alluded; want of knowledge, because, as the principles of the fine arts are founded partly on general nature, and partly on arbitrary rules, no just judgment can be formed of their general nature without much attention and experience; and the arbitrary rules pertaining to all the arts are numerous and complicated, and easily confounded by unskilful judges; and further, hastiness or precipitance of decision, by which men are often misled. Having already remarked, that the laws of taste are partly natural, and partly arbitrary, we here suggest, that under the former fall, in poetry and eloquence, whatever suggests associations generally delightful and interesting, or awakens sympathies, which the constitution of mankind leads them to feel; in painting, truth of imitation, and forcibleness of expression; in music, gratification of the ear and power over the affections. Under the latter may be reckoned, what is called, style in writing, and the observance of those rules with which critics are conversant, in the other arts. Besides, independently of principles of approbation and disapprobation which exist in the objects of taste, all men are more or less influenced by circumstances peculiar to themselves; and to this class belongs a variety of accidental associations.

A late excellent writer has defined taste to be the power of receiving pleasure from the beauties of nature and of art. Though taste, says this writer, be ultimately founded on a certain natural and instinctive sensibility to beauty, yet reason assists taste in many of its operations, and serves to enlarge its power. In this sense, it is a faculty common in some degree to all men. Quintilian, however, (Instit. lib. vi. c. 3.) seems to include taste under what he calls *judicium*. The characters of taste, when brought to its most perfect state, are all reducible to two, delicacy, which principally respects the perfection of that natural sensibility on which taste is founded; and correctness, which chiefly respects the improvement that faculty receives through its connection with

the

the understanding: the former of these qualities is more the gift of nature; the latter more the product of culture and art. Among the ancient critics, Longinus possessed most delicacy; Aristotle most correctness. Among the moderns, Mr. Addison is a high example of delicate taste; and dean Swift, if he had written on the subject of criticism, would perhaps have afforded the example of a correct one. In determining the standard of taste, those who say that nature is this standard, lay down a principle very true and just, as far as it can be applied: nevertheless, conformity to nature is an expression very often used, without any distinct or determinate meaning: in a more clear and precise sense, nothing can be considered as the standard of taste, but the taste, as far as it can be known, of human nature. That which men concur the most in admiring, must be held to be beautiful. His taste must be esteemed just and true, which coincides with the general sentiments of men. In this standard we must rest. To the sense of mankind the ultimate appeal must ever lie, in all works of taste. But this sense is founded on those principles of reason and sound judgment, which are applicable to matters of taste: and yet the ultimate conclusions to which our reasonings lead, refer at last to sense and perception. Accordingly it is observed, that the difference between the authors who found the standard of taste upon the common feelings of human nature, ascertained by general approbation, and those who found it upon established principles, which can be ascertained by reason, is more an apparent than a real difference. For they who lay the greatest stress on sentiment and feeling, make no scruple of applying argument and reason to matters of taste; they appeal to established principles, and plainly shew that the general approbation to which they ultimately recur, is an approbation resulting from discussion as well as from sentiment. And they, on the other hand, who, in order to vindicate taste from any suspicion of being arbitrary, maintain that it is ascertainable by the standard of reason, admit, nevertheless, that what pleases universally, must on that account be held to be truly beautiful: and that no rules or conclusions concerning objects of taste, can have any just authority, if they be found to contradict the general sentiments of men.

However, it is not pretended, that there is any standard of taste, to which, in every particular instance, we can resort for clear and immediate determination. But it is sufficient to conclude, that taste is far from being an arbitrary principle, which is subject to the fancy of every individual, and which admits of no criterion for determining whether it be false or true. Its foundation is the same in all human minds. It is built upon sentiments and perceptions, which belong to our nature; and which, in general, operate with the same uniformity as our other intellectual principles. When they are perverted by ignorance or prejudice, they are capable of being rectified by reason. Their sound and natural state is ultimately determined by comparing them with the general taste of mankind.

The ingenious writer to whom we are indebted for the preceding observations, has distinguished between taste and genius. See GENIUS.

Mr. Alison has treated the subject of this article with so much ingenuity and elegance, in his "Essay on the Nature and Principles of Taste," that it would be almost sufficient, without further enlargement, to refer to his excellent performance.

According to this much approved writer, the perception of the qualities that are denominated *beautiful* and *sublime* in the works of nature and art, is attended with an emotion of pleasure, very distinguishable from every other pleasure of

our nature, and to which is appropriated the name of the "emotion of taste." Accordingly, the distinction of the objects of taste into the *sublime* and *beautiful*, has produced a similar division of this emotion into the "emotion of sublimity" and the "emotion of beauty." The qualities that produce these emotions occur amid every variety of *external scenery*, and among many diversities of disposition and affection in the mind of man. The most pleasing arts of human invention are altogether directed to their pursuit, and even the necessary arts are exalted into dignity by the genius that can unite beauty with use.

Our author, in his prosecution of this subject, first investigates the nature of those qualities that produce the emotions of taste, and then the nature of the faculty by which these emotions are received. He observes, that the theories which have been formed in relation to this subject have uniformly taken for granted the *simplicity* of this emotion, and have referred it to some *one* principle or law of the human mind; and have therefore concluded, that the discovery of that *one* principle was the essential key by which all the pleasures of taste were to be resolved. These theories are arranged, in consequence of the assumption of this fundamental principle, into two classes of supposition: *one*, which reduces the "emotion of taste" directly into an original law of our nature, which supposes a sense, or senses, by which the qualities of beauty and sublimity are perceived and felt, as their appropriate objects; and hence concludes, that the genuine object of the arts of taste is to discover and to imitate those qualities in every subject, which the prescription of nature has thus made essentially either beautiful or sublime. To this first class of hypotheses belong almost all the theories of music, architecture, and sculpture, the theory of Mr. Hogarth, of the abbé Winkelman, and, perhaps, in its last resort, also the theory of sir Joshua Reynolds; and of all those who attend more to the causes of these emotions, than to their nature. The *second* class of hypotheses refutes the idea of any new or peculiar sense, distinct from the common principles of our nature; which supposes some *one* known and acknowledged principle or affection of mind to be the foundation of all the emotions we receive from the objects of taste; and, therefore, resolves all the various phenomena into some more general law of our intellectual or moral constitution. Of this kind are the hypotheses of M. Diderot, who attributes all our emotions of this kind to the perception of relation; of Mr. Hume, who resolves them into our sense of utility; of the venerable St. Austin, who, with nobler views, one thousand years ago, resolved them into the pleasure which belongs to the perception of order and design, &c. This hypothesis has been adopted by rational and philosophic minds: by those who have been led by their habits to attend more to the nature of the emotions they felt than to the causes which produced them. Mr. Alison, pursuing an analysis of the effect which is produced upon the mind, when the emotions of beauty or sublimity are felt, concludes that it is very different from the determination of a "sense;" that it is not a simple but a complex emotion; that it involves, in all cases, the production of some simple emotion, or the exercise of some moral affection, and the consequent excitement of a peculiar exercise of the imagination; that these concomitant effects are distinguishable, and very often distinguished in our experience; and that the *peculiar* pleasure of the beautiful and sublime is only felt when these two effects are conjoined, and the complex emotion produced.

Our author having investigated the causes which produce this effect, or, in other words, the sources of the beautiful and sublime in nature and art, and having shewn that there is

no single emotion into which these varied effects can be resolved; but, on the contrary, that every simple emotion, and therefore every object capable of producing any simple emotion, *may be* the foundation of the complex emotion of beauty or sublimity; and that this complex emotion is never produced, unless, besides the excitement of some simple emotion, the imagination also is excited, and the exercise of the two faculties combined in the general effect;—proceeds to shew what is that “law of mind,” according to which, in actual life, this exercise of imagination is excited, and what are the means by which, in the different fine arts, the artist is able to awaken this important exercise of imagination, and to exalt objects of simple and common pleasure into objects of beauty and simplicity. In the last place, he investigates the nature of that faculty by which the emotions described by him are perceived and felt. This he shews has no resemblance to a sense; wherever it is employed, two distinct and independent powers of mind are engaged, so that it is not to be considered as a separate and peculiar faculty, but to be finally resolved into some general principles of our constitution. These speculations further lead to the important enquiry, whether there is any standard by which our sentiments on these subjects may be determined; to an explanation of the means by which taste may be corrected or improved; and to an illustration of the purposes which this peculiar constitution of our nature serves; in the increase of human happiness, and the exaltation of human character. Our limits will not allow any further abstract or abridgment of this valuable work; and we must refer those readers who wish to pursue disquisitions of this kind to the work itself, in 2 vols. edit. 4, 1815.

We cannot forbear citing some pertinent remarks, that are presented to our notice by a living writer of distinguished celebrity, professor Dugald Stewart. Taste, says this author, is not a simple and original faculty, but a power gradually formed by experience and observation. It implies, as its ground-work, a certain degree of natural sensibility; but it implies also the exercise of the judgment, and is the slow result of an attentive examination and comparison of the agreeable and disagreeable effects produced on the mind by external objects. In tracing the progress of taste from rudeness to refinement, we find an analogy to the progress of physical knowledge from the superstitions of a savage tribe to the investigation of the laws of nature, founded on the supposition, that, as in the material world there are general facts beyond which philosophy is unable to proceed, so, in the constitution of man, there is an inexplicable adaptation of the mind to the objects with which his faculties are conversant, in consequence of which, these objects are fitted to produce agreeable or disagreeable emotions. In both cases, reasoning may be employed with propriety to refer particular phenomena to general principles; but in both cases, we must at last arrive at principles of which no account can be given, but that such is the will of our Maker. In matters of taste it should be considered, that the tendency to casual association is much stronger than it commonly is, with respect to physical events; and when such associations are formed, they are not so likely to be corrected by mere experience, unassisted by study. Hence some have erroneously supposed, that association is sufficient to account for the origin of the notions we form concerning matters of taste; and that there is no such thing as a standard of taste founded on the principles of the human constitution. Whenever, says our author, association produces a change in our judgments on matters of taste, it does so by co-operating with some natural principle of the mind, and implies the existence of certain original sources of pleasure and unplea-

ness. The circumstances which please, in the objects of taste, are of two kinds: 1st. Those which are fitted to please by nature, or by associations, which all mankind are led to form by their common condition; and, 2dly. Those which please in consequence of associations arising from local and accidental circumstances. Hence we derive two kinds of taste; the one enabling us to judge of those beauties which have a foundation in the human constitution; the other, of such objects as owe their principal recommendation to the influence of fashion. These two kinds of taste are not always, indeed rarely, united in the same person. The perfection of the one depends upon the degree in which we are able to free the mind from the influence of casual associations: that of the other, on the contrary, depends on a facility of association, which enables us to fall in, at once, with all the turns of the fashion, and (as Shakspeare expresses it) “to catch the tune of the times.” For the author’s application of his principles and remarks to the subject of language, which affords numberless instances to exemplify the influence which the association of ideas has on our judgments in matters of taste, we must refer to his own valuable work. See Dr. Blair’s Lectures on Rhetoric, and Belles Lettres, vol. i. lect. ii. and iii. See also Hume’s Essay of the standard of taste, in his Essays, &c. vol. i. eff. xxiii. p. 253, edit. 1764. Stewart’s Elements of the Philosophy of the Human Mind, part ii. ch. v. § 2. Knight’s Analyt. Enq. into the Principles of Taste, 8vo. 1805. Alison on Taste, 2 vols. 8vo. 1815. Edin. Rev. N° XIV.

TASTE, in *Music*, is often confounded with *graces*, or change of passages; but a movement composed in good taste, is often injured by what are called graces. We rather suppose taste to depend on feeling and expression, than in flourishes, or, as the Italians call them, *riffioramenti*; in sorrow, pathos; in joy, brilliancy and fire. Yet when changes and embellishments are necessary, good taste is likewise requisite in their choice and application. The composer discovers his taste by his melodies, as much as the performer by expressing his thoughts.

Taste, says Rousseau, is of all Nature’s gifts the most easily felt, and the most difficult to explain; it would not be what it is, if it could be defined: for it judges of objects beyond the reach of judgment, and serves, in a manner, as a magnifying glass to reason.

There are some melodies more agreeable than others, though equally well phrased and modulated; there are combinations in harmony of great effect, and others that excite no attention, all equally regular as to composition; there is in the texture of the parts, an exquisite art of arranging and setting off one passage by another, which depends on something more subtle than the laws of contrast.

Genius creates, but taste selects. Genius is often lavish and redundant, and in want of a severe critic to prevent him from the abuse of his riches. Many great things may be achieved without taste; but it is taste that renders them interesting. It is taste which enables a vocal composer to seize and express the ideas of the poet; it is taste which guides the performer to the true expression of the composer’s ideas; it is taste which furnishes both with whatever can embellish and enrich the subject; and it is taste which enables the hearer to feel all these perfections. Taste is, however, not mere sensibility. A cold heart may have much taste; and a man transported with things truly spirited and impassioned, is little touched by grace and elegance. It seems as if taste attached itself to minute refinements, and sensibility to grand and sublime effects.

TASTE in *singing and playing*; *Gout du Chant*, Fr. According to Rousseau, there was, in his time, in France, a person

person distinct from the music-master, to teach the necessary *agrémens* or graces thought necessary to cover, in some degree, the insipidity of French melody. Most of the young students in music used therefore to have two masters, one for music and one for taste, called *Maitre de Gout-de-chant*.

Gout-de-chant likewise consisted in imitating or *taking-off* the voice and manner of a particular singer; which is always done by exaggeration. The face of a man with a mole or wart upon it, is of great use to a portrait painter in fixing a likeness: so a singer, with a little tendency to nasalty, to coarseness, to singing through the throat, or of quivering upon one note in attempting to shake, which the Italians have well denominated *tosse di capra*, a goat's cough, are easily taken off.

TASTINA, in *Ancient Geography*, a town of Asia, in the Greater Armenia, between Surta and Cozala. Ptol.

TASTING, the sense by which we distinguish favours; or the perception which the soul has of external objects, by means of the organs of taste.

Authors differ much as to the organ of tasting. Bauhin, Bartholin, Veltingius, &c. place it in the laxer fleshy parts of the tongue; Dr. Wharton, in the glands at the root of the tongue; Laurentius, in the thin tunic covering the tongue; others in the palate, &c. But the great Malpighi, and after him all the latest writers, place it in the papillæ chiefly lying about the tip and sides of the tongue. See TONGUE.

These papillæ arise from the corpus nervosum, which covers the muscular flesh of the tongue; whence, passing through the corpus reticulare, they stand up under the external membrane of the tongue, erect, and covered with vaginæ, or sheaths of the said membrane, to defend them from objects too violent. These vaginæ are porous, and stick out so far, that when the aliment is squeezed, they enter with the same to receive the object, or the matter of taste.

These papillæ Boerhaave conjectures to arise from the ninth pair of nerves; and these, he asserts, are the only organ of taste: the others, whether of the tongue, palate, or jaws, &c. he observes, contribute nothing to them; though probably those of the cheeks next the dentes molares may.

The object of tasting, is any thing, either in animals, vegetables, or minerals, from which salt or oils may be extracted.

Tasting, then, is performed by the objects being attenuated and mixed with saliva, warmed in the mouth, and applied to the tongue; where, insinuating into the pores of the membranous vaginæ of the nervous papillæ, and penetrating to the surface of the papillæ themselves, it affects and moves them: by which means a motion is communicated along the capillaments of the nerve to the common sensory, and an idea excited in the mind, of salt, acid, sweet, bitter, hot, aromatic, austere, or the like; according to the figure of the particles that strike the papillæ, or the disposition of the papillæ to receive the impulse.

The taste, considered in a medical view, may be diminished by crusts, filth, mucus, aphthæ, pellicles, warts, &c. covering the tongue: it may be depraved by a fault of the saliva, which, being discharged into the mouth, gives the same sensation as if the food which the person takes had really a bad taste; or it may be entirely destroyed by injuries done to the nerves of the tongue and palate. Few things prove more hurtful, either to the sense of tasting or smelling, than obstinate colds, especially those which affect the head. When the taste is diminished by filth, mucus, &c. the tongue ought to be scraped, and frequently washed

with a mixture of water, vinegar, and honey, or some other detergent. When the saliva is vitiated, which seldom happens, unless in fevers or other diseases, the curing of the disorder is the cure of this symptom. To relieve it, however, in the mean time, the following things may be of use: if there be a bitter taste, it may be taken away by vomits, purges, and other things, which evacuate bile: what is called a nidorous taste, arising from putrid humours, is corrected by the juice of citrons, oranges, and other acids: a salt taste is cured by plentiful dilution with watery liquors: an acid taste is destroyed by absorbents, and alkaline salts, as powder of oyster-shells, salt of wormwood, &c. When the sensibility of the nerves, which supply the organs of taste, is diminished, the chewing of horse-radish, or other stimulating substances, will help to recover it.

TASTNESS, in *Geography*, a cape on the N. of the island of Sanday. N. lat. 59° 10'. W. long. 2° 20'.

TASTO, in *Italian Music*, the touch or part of any instrument, whereon, or by means of which its notes are made to sound, be it on the neck, as lutes, viols, &c. which are called fixed and immoveable; or the front of organs, spinets, or harpsichords, where the keys are disposed to raise the jacks, called moveable touches; and is properly no more than the finger-board of each.

TASTO Solo. These two Italian words, written over or under a base to solos that are figured, generally at a pause, or preceding a close, imply that the accompanier on a keyed-instrument ought to play no chords with the right hand; but only to strike the base note with the left hand, which is implied by the word *tasto solo*, a single key; or at most to double that sound with the right hand in the octave: as it is hardly possible to divine or figure the harmony of an *ad libitum* or cadence, either written or played extempore, which the composer or the performer is allowed to write or play on these occasions. Solos are now no longer in fashion; but the violin solos of the early part of the last century, by Corelli, Geminiani, Somis, and Tartini, have all closes of this kind, to which the base is confined to a single note, or *tasto solo*.

TATA, or DOTIS, in *Geography*, a town of Hungary, built in the midst of water and swamps, with a castle; 20 miles W. of Gran.

TATA Youba, in *Botany*, a name used by some for the tree which yields what the dyers call the fustic, or yellow wood used in dyeing.

TATACUL, in *Geography*, a town of Hindoostan, in Mysore; 11 miles N. of Vencatighery.

TATALISGA, a town of Africa, in Galam, on the Senegal; 60 miles W. of Galam.

TATAPARY, a town of Hindoostan, in the province of Tinevelly; 15 miles N.E. of Palamcotta.

TATAPATNAM, a town of Hindoostan, in Bara-maul; 22 miles S.S.E. of Darempoury.

TATAR BASSARDDSCHII, a town of European Turkey, in Romania, on the Mariza; 16 miles N.N.W. of Filipopoli.

TATAR Bunar, a town of European Turkey, in Bessarabia; 32 miles S.W. of Akerman.

TATARSKOI, a fort of Russia, in the government of Kolivan, on the E. side of the Irtsch. N. lat. 53° 44'. E. long. 85° 34'.

TATENAGUR, a town of Hindoostan, in the Carnatic; 6 miles S.W. of Devicotta.

TATENAY, the chief town of the island *Gilolo*; which see.

TATH, in *Old Laws*, a privilege which some lords of manors enjoyed, of having their tenants' sheep folded at

right on their demefne lands, for the improvement of the ground.

TATH, in *Agriculture*, a term applied by flock-farmers, in fome fituations, to all fuch graffes as are particularly rank and luxuriant, and which have a tendency to induce the rot in fheep.

They commonly diftinguifh two kinds of it; namely, the *water-tath*, which arifes and proceeds from an excefs of moifture; and the *nolt-tath*, which is the produce of dung. The latter, it is faid, is darker coloured than the former; but that their foftnefs, luxuriancy, and tendency to produce the rot in the animals, are nearly the fame. The water-tath is noticed to be the produce of either lands naturally too moift, or of wet feafons, of accidental or artificial floodings of them, or of fome other fuch caufes. Nothing is fo apt, it is fupposed, to produce the rot in thefe animals, as the grafs which grows in low marfhy grounds, in what is called *awald* lands, and that around the heads of fprings, efpecially on the north fide of hills, infomuch fo, indeed, that fuch paftures were formerly confidered as naturally rotten, and of courfe rejected by all intelligent fheep-farmers.

In fhort, wherever a very foft and tender tath fuddenly rushes up in fheep-pafture lands, there is always much danger of its effects; and as dung greatly promotes the growth of very rank tath, the pernicious confequences of fuch nolt-tath are to be remedied, by not allowing horfes or neat cattle to pafture among the fheep.

TATHAA, in *Geography*, a river of Africa, which runs into the Indian fea, S. lat. 28° 20'.

TATHILBA, in *Ancient Geography*, a town of India, on this fide of the Ganges, which belonged to the Bidamæi. Ptolemy.

TATIAMBETTY, in *Geography*, a town of Hindooftan, in Myfore; 5 miles N. of Wombinellore.

TATIAN, in *Biography*, a native of Affyria, from which circumftance he is fometimes called "the Affyrian," and an ecclefiaftical writer, who, according to Cave, flourifhed about the year 172. He was originally a heathen, and by profefion a fophift, and teacher of rhetoric. His reading appears to have been extenfive, and he is allowed to have been well acquainted with Grecian literature and philofophy. After his converfion to Chriftianity, he became a difciple of Juftin Martyr, to whom he was attached, and of whom he fpeaks with great refpect. He accompanied this father to Rome, and travelled through different countries with a view to his improvement. But fome time after Juftin's death, which happened about the year 165, he adopted a number of abfurd opinions. Accordingly he is charged, and probably not without reafon, with being the founder of the feét of the Encratites; he condemned the ufe of wine, and denied the lawfulness of marriage, the reality of Chrift's fufferings, and the falvation of Adam. He alfo embraced the Æons of Valentinus, and asserted with Marcion, that there are two gods. Eufebius dates his herefy about the twelfth year of the emperor Marcus Antoninus, or the year 172. But however erroneous were his principles in the latter part of his life, his works afford us fatisfactory evidence of the antiquity and high efteem of the gospels in his time. After propagating his doctrines for fome time at Rome, he opened a fchool in Mefopotamia, about the year 172: and he is faid to have preached at Antioch, and in fome other places. The place and time of his death are not known. He appears to have written a confiderable number of books, one of which, ftill extant in Greek, and entitled "Oratio ad Græcos," or Oration againft the Gentiles, was either an apology for Chriftianity, or an attack on Heathenifm. This was firft printed at Zurich in 1546, with the Latin verfion of Conrad Gefner. It is an-

nexed to the edition of Juftin Martyr's works, and thofe of other fathers: but the beft edition is that of Worth, Greek and Latin, Oxon. 1700, 8vo. His defign in this work, which difplays great learning, was to prove that the Greeks were not the inventors of any of the fciences, but that they were indebted for their acquaintance with them to thofe whom neverthelefs they denominated Barbarians. This work, according to Brucker, every where breathes the fpirit of the Oriental philofophy, the leading tenets of which he details; and he feems to have adopted feveral of the opinions of Plato, and of the Alexandrian Platonifts, concerning the creation of the world by the Logos, and its animation by a fubordinate fpirit; concerning the exiftence of demons in material vehicles, who occupy the aerial regions, and that of æons, who refide above the ftars. He alfo held with Plato the imperfection of matter as the caufe of evil, and thence he inferred the meritorioufnefs of rifing above corporeal appetites and paffions. Another work of Tatian, cited by St. Clement, was entitled "Perfection according to the Saviour," in which he argued againft marriage. Eufebius cites another work compofed by Tatian, which was a "Book of difficult queftions, for the explication of feveral obfcure places of Scripture." We have alfo in Latin a work afcribed to Tatian, called "Harmony" or "Dia-Teffaron" of the Four. But fome approved writers have doubted whether we have one copy of Tatian's Harmony now extant. Dr. Lardner has investigated this fubject with his ufual judgment and impartiality: and he inclines to the opinion, that we are in poffeffion of this work: and he thinks that the commentaries written upon it by Ephrem, the Syrian, afford reafon for concluding that it was not fo contemptible or fo heretical as fome have thought. This Harmony is fhorter than that attributed to Ammonius, and contains a compendious hiftory of our Lord and Saviour Jefus Chrift, taken out of the four Gospels. It confifts of four parts; the firft is a kind of introduction, containing the hiftory of our Lord's nativity, and the former part of his life; the other three parts are the three years of our Lord's miniftry. Brucker by Enfield. Lardner's Works, vol. ii.

TATIANITES, **TATIANITÆ**, in *Ecclefiaftical Hiftory*, a feét of ancient heretics; thus called from Tatian, a difciple of Juftin Martyr.

This Tatian, who has the character of one of the moft learned men of all antiquity, was perfectly orthodox during the life of his mafter. He was, like him, a Samaritan, by nation, not by religion, as Epiphanius feems to infinuate. They both belonged to the Greek colonies which were fpread throughout the country of the Samaritans.

Juftin being dead, Tatian is faid by fome to have inclined to many of the errors of the Valentinians; but Moſheim fays, that his doctrine approached nearer to that of the oriental philofophy concerning the two principles. He adds, that it appears from the testimony of credible writers, that Tatian looked upon matter as the foundation of all evil, and therefore recommended, in a particular manner, the mortification of the body; that he diftinguifhed the creator of the world from the Supreme Being: denied the reality of Chrift's body; and corrupted the Chriftian religion with feveral other tenets of the oriental philofophy. (See the preceding article.) He had a great number of followers, who were, after him, called *Tatianifts*; but were neverthelefs more frequently diftinguifhed from other feéts, by names relative to the austerities of their manners. For as they rejected, with a fort of horror, all the comforts and conveniences of life, and abftained from wine with fuch a rigorous obftinacy, as to ufe nothing but water, even at the celebration of the Lord's fupper; as they macerated their bodies by continual fafting, and lived a fevere life of

celibacy and abstinence; so they were called Eueratitæ, or temperate; Hydroparastatæ, or drinkers of water; and Apotactitæ, or renouncers. Mosh. Eccl. Hist. vol. i.

TATIANSKAIA, in *Geography*, a fort of Russia, in the government of Saratov, on the Volga; 12 miles S.E. of Tzaritzin.

TATIEN, a town of Chinese Tartary; 55 miles N.E. of Tam-fan.

TATILLUM, in *Ancient Geography*, a town of Africa, in Mauritania Cæsariensis, on the route from Carthage to Cæsarea, between Aræ and Aufa. Anton. Itin.

TATISCHEVA, in *Geography*, a fortress of Russia, in the government of Upha, on the Ural; 28 miles W. of Orenburg.

TATISM KÖH, a mountain of Persia, in the province of Irak; 12 miles N. of Com.

TATIUS, ACHILLES, in *Biography*, a Greek writer of Alexandria, is supposed to have lived in the latter part of the third century. He is known to us as the author of a work on the Sphere, of which there remains a fragment, being an introduction to a commentary on the Phenomena of Aratus. A copy of this from a MS. in the Florentine library, by Peter Victorius, was printed. It was afterwards translated into Latin by Petau, under the title of "Ifagoga in Phænomena Arati." We learn from Suidas, that Tattius also wrote "Erotics," in which he includes "the Loves of Leucippe and Clitophon." This work is preserved, and affords one of the examples of Greek romance. The Latin version of it was made by Annibal Cruceius, and published at Basil in 1554. The latest edition of this piece is that of Bodem, Greek and Latin, Lips. 1776, 8vo. It is elegantly written, but of a licentious cast; and hence it has been inferred that the author was a heathen, when he composed it; but Suidas affirms, that he afterwards became a Christian, and attained to episcopacy.

TATNALL, in *Geography*, a county of the State of Georgia.

TATOBIT, a town of Bohemia, in the circle of Bolef-lau; 5 miles E. of Turnau.

TA-TOU-CHE, a town on the W. coast of the island of Formosa. N. lat. 24° 8'. E. long. 119° 58'.

TA-TSIN, a river of China, which runs into the sea, N. lat. 37° 46'. E. long. 118° 19'.

TATTA, supposed to be at or near the ancient *Pattala*, a town of Asia, which, before the building of Hyderabad, was considered as the chief city of Scind, was founded, according to the tradition of the natives, in the 906th year of the Hegira, and stands on a rising ground, four miles W. of the Indus. It has still a population of 18,000 souls, and is about four miles and a half in circumference. Its wall, constructed for its defence, is now in ruins. The houses of the higher rank are built of bricks, but those of the lower class of wood, plastered with mud. The remains of the mosques, and other handsome edifices of this city, are evidences of its former prosperity; and although on the decline, it enjoys a considerable trade. Its trade is much diminished, on account of the bad government of Scind or Sindy, and the hostile or rapacious disposition of the Seiks, the present possessors of the countries of Moultan and Lahore. The country in the vicinity is a fine rich soil, being watered by canals drawn from the river. Agriculture, however, is much neglected, and the inhabitants of Tatta indicate extreme poverty and wretchedness. To the north of the city is a range of hills, extending several miles in a northerly direction; and to the south is also a range of Table land, reaching almost to the banks of the Indus. Boats trading to Tatta come no farther than Begemah, a village at the distance of about five miles. The

river at this place is about a mile in breadth, and four fathoms in depth in the deepest parts. N. lat. 24° 44'. E. long. 68° 17', as stated in Kinneir's account of Persia; but according to major Rennell, N. lat. 24° 50'. E. long. 67° 37'.

TATTAH, a town of Africa, on the frontiers of Drali and Morocco, in the route from Morocco and Sufe to Tombuctoo; 170 miles S.S.E. from Morocco. N. lat. 28° 25'. W. long. 6° 15'. Tattah and its territory contain 10,000 inhabitants. Jackson's Morocco.

TATTAHAR, a town of Bengal; 13 miles N. of Toree.

TATTAMUNGALUM, a town of Hindoostan, in Calicut; 5 miles S. of Palicandery.

TATTAR. See Yool.

TATTARAN, a small island in the Sooloo Archipelago. N. lat. 6° 10'. E. long. 121° 58'.

TATTERSHALL, a small market-town in the wapentake of Gartree, Lindsey division of the county of Lincoln, England, is situated on the river Bain, near its junction with the Witham, 9 miles S.S.W. from Horncastle, and 130 miles N. from London. The manor was granted by William the Conqueror to Eudo, one of his Norman followers, whose descendants assumed the name of Tattershall, from this place. Robert Fitz-Eudo obtained a grant from king John, for the inhabitants of the town to hold a weekly market; and another of the family, in the time of Edward III., received the royal licence to erect a castle within his manor of Tattershall. But the present fortress was built by sir Ralph, afterwards lord Cromwell, treasurer of the Exchequer to Henry VI. The castle and manor were granted by Henry VII. to Margaret, countess of Richmond, and entailed on the duke of Richmond; who dying without issue, they were granted by Henry VIII. to the duke of Suffolk; and in the next reign passed to Edward, lord Clinton, afterwards earl of Lincoln. By marriage with an heiress of the Clintons, they are now in the possession of lord Fortescue. The castle stands on a level moor, and is surrounded by two great fosses, the outer one formed of earth, and the inner faced with brick, ten feet deep. It was originally intended as a place of defence, and was progressively raised to great height and extent. In the civil wars it was, however, dilapidated. Till very lately the principal gateway was remaining: the part at present left standing, is a square tower of brick, flanked by four octangular embattled turrets, which are crowned with spires covered with lead. It was divided into four stories. The main walls were carried to the top of the fourth story, where a capacious machicolation surrounded the tower, on which there is a parapet wall of great thickness. This was to protect the persons employed at the machicolations. The tower is constructed upon ponderous groined arches, which support the ground-floor. Near the outer moat stands the parish church, a beautiful and spacious edifice, built in form of a cross. Few churches, perhaps, have suffered more dilapidations than this. It consisted of a nave, having five large arches on a side, and eight clerestory windows, placed in pairs; on each side is a transept, and a magnificent choir. The windows of the latter were glazed with stained glass, which was removed, by a late earl of Exeter, to the chapel of Burleigh, on condition that he replaced it with plain glass, which could have been done for the sum of forty pounds; but this being neglected, the inside has suffered greatly from the weather; although the walls, roof, and pavement remain almost entire. The ruined screen and stalls of wood, richly carved, are almost rotten: behind it is a stone screen, in the arches of which are painted figures. The body of the church and transepts had their windows richly adorned with the legendary histories

lives of Romish saints. Before the altar lay two rich brass figures of Ralph, lord Cromwell, who died in 1455, and of Margaret his wife, who died in 1453. This nobleman, in the seventeenth year of Henry VI., obtained a licence to make the church of Tattershall collegiate, for a master or warden, six priests, six secular clerks, and six choristers. He also founded, near the church-yard, an hospital or almshouse, for thirteen poor men and women. At the dissolution, the collegiate revenues were granted to Charles, duke of Suffolk. The hospital still remains, with a small endowment. The population report of the year 1811, stated that Tattershall contained 506 inhabitants, occupying 105 houses. The market is held on Tuesdays, and there are three fairs annually.—*Beauties of England and Wales*, vol. ix. Lincolnshire, by J. Britton, F.S.A. *History, &c. of Tattershall*, with plates, 8vo. 1801.

TATTICOMBA, a town of Hindoostan, in Mysore; 4 miles N. of Dindigul.

TATTO, Ital. from *Tactus*, Lat. in *Musick*, implies a measure, or bar, the period when the hand or foot is beaten down in marking the time. See TACTUS, and BATTUTA.

TAT-TOO, *q. d. Tap-to*, a beat of a drum, at night, to advertise the soldiers to retreat, or repair to their quarters in a garrison, or to their tents in a camp. See RETREAT.

TATTOOING, in *Modern History*, a name given at Otaheite, and other islands of the South sea, to the operation of staining the body. For this purpose they prick the skin, so as just not to fetch blood, with a small instrument, somewhat in the form of a hoe, or blade of a saw: that part which answers to the blade is made of a bone or shell scraped very thin, and from a quarter of an inch to an inch and a half wide: the edge is cut into sharp teeth or points, from the number of three to twenty, according to its size. When this is to be used, they dip the teeth into a mixture of a kind of lamp-lack, formed of the smoke that rises from an oily nut which they burn instead of candles, and water, or charcoal-dust diluted with water; the teeth, thus prepared, are placed upon the skin, and the handle to which they are fastened, being struck by quick smart blows, with a stick fitted for the purpose, they pierce it, and at the same time carry into the puncture the black composition, which leaves an indelible stain. This operation is performed upon the youth of both sexes, when they are about twelve or fourteen years of age, in several parts of the body, and in various figures, according to the fancy of the parent, or perhaps the rank of the party. The women are generally marked with this stain in the form of a Z, in every joint of their fingers and toes, and frequently on the outside of their feet: the men are also marked with the same figure; and both men and women have squares, circles, crescents, and ill-designed representations of men, birds, or dogs, and various other unintelligible devices, impressed upon their legs and arms. But the part on which these ornaments are lavished with the greatest profusion is the breech; this, in both sexes, is covered with a deep black; above which, arches are drawn over one another, as high as the short ribs. These are often a quarter of an inch broad, and the edges are indented. These arches are exhibited, both by the men and the women, with singular ostentation. The face in general is left unmarked. Some old men had the greatest part of their bodies covered with large patches of black, deeply indented at the edges, like a rude imitation of flame. It is only at New Zealand, and in the Sandwich islands, that they tattoo the face. There is also this difference between the two last, that, in the former, it is done in elegant spiral volutes, and in the latter, in straight lines, crossing each other at right angles. The hands and arms of the women are very neatly marked, and they have

among them a singular custom, the meaning of which could not be learned, that of tattooing the tip of the tongues of the females. This custom of tattooing, it is apprehended, is frequently designed as a sign of mourning on the death of a chief, or any other calamitous event. Persons of the lowest class are often tattooed with a mark, that distinguishes them as the property of the several chiefs to whom they belong. Hawkesworth's *Voyages*, vol. ii. p. 189. Marchand's *Voyage*, vol. i. p. 99. Cook's *Third Voyage*, vol. iii. p. 155.

TATTUBT, anciently TADUTTI, in *Geography*, a town of Algiers, formerly a considerable city, now almost completely in ruins: some beautiful granite pillars were dug up some years ago, and placed in a mosque at Constantina; 25 miles S. of Constantina.

TATU, in *Ancient Geography*, an island situated in the Nile, in the vicinity of the town of Meroc. Pliny.

TATU, in *Zoology*, the Brazilian name for the armadillo, or shell-hedge-hog, or *dasyfus* of Linnæus. See DASYPUS.

TATU-Apara, the name of a creature of the armadillo kind, being the three-banded or *tricinctus dasyfus* of Linnæus. See DASYPUS.

This animal burrows under ground, keeps its hole in the day, and rambles out at night: when it would sleep, or when it is afraid of being taken up, it contracts its crust into a round figure; and hiding its whole body within, it might sooner be taken for a sea-shell than a land-animal. It is hunted with little dogs, feeds on potatoes, &c. drinks much; grows very fat, and is reckoned delicious eating when young, but when old, has a musky disagreeable taste; breeds every month, and brings four at a time. Ray and Pennant.

TATU-*Mustelinus*, the *Weasel-banded Armadillo*, the name of a small animal of the armadillo kind. This is the *dasyfus uncinatus* of Linnæus, and banded armadillo of Pennant: it has a very slender head, small erect ears, the crust on the shoulders and rump consisting of square pieces; eighteen bands on the sides; five toes on each foot; length from nose to tail about fifteen inches; the tail five and a half. It inhabits South America. Ray, Pennant, and Grew's *Mus. Reg. Soc.* p. 19.

TATU-*Paba* of Brasil, is the six-banded *dasyfus* of Linnæus, having the crust of the head, shoulders, and rump, formed of angular pieces, and between the bands, and also on the neck and belly, a few scattered hairs; the tail thick at the base, tapering to a point, and not so long as the body, and five toes on each foot. It inhabits Brasil and Guiana. Pennant.

TATU-*Porcinus*, the name of the pig-headed armadillo, or nine-banded *dasyfus* of Linnæus, with long ears, crust on the head, shoulders, and rump, marked with hexangular figures; the nine bands on the sides distinguished by transverse cuneiform marks; breast and belly covered with long hairs; four toes on the fore-feet, and five on the hind; the tail taper, and a little longer than the body; and length of the whole animal three feet. This animal inhabits South America: and one, that was brought into England a few years ago from the Mosquito shore, was fed with raw beef and milk, but refused our grains and fruit. Pennant.

TATUETE, the name of a species of tatu, or armadillo, being the nine-banded *dasyfus* of Linnæus, though Buffon and Pennant ascribe to it only eight bands; it has upright ears, two inches long; small black eyes; four toes on the fore-feet, and five on the hinder ones; the length from nose to tail about ten inches, the tail nine: it is of an iron colour on the back, and whitish at the sides; its belly also is whitish and naked, except for a few hairs. It inhabits Brasil.

The flesh of this is accounted more delicious than that of any other creature of this kind, though they may all be eaten. Ray and Pennant.

TATULA, in *Botany*, a name used by Clusius, and some other authors, for the stramonium, or thorn-apple.

TATZO, in *Geography*, a town of Hungary; 40 miles E. of Munkacz.

TAU, in our *Ancient Customs*, signifies a cross.

"Tradendo dicto comiti Thau eboreum." So Mr. Selden, in his notes upon Eadmerus, p. 159. "Ego Eadgisa prædicti regis ava hoc opus egregium crucis Taumate consolidavi." See Mon. tom. iii. p. 121.

TAU, in *Entomology*, a species of beetle. See SCARABÆUS.—Also, a species of *Phalena bombyx*.—Also, a species of *Musca*.

TAU, or *Taw*, in *Heraldry*, an ordinary, in figure of a T, supposed to represent St. Andrew's cross, or a cross potent, the top part cut off.

It is thus called from the name of the Greek T, *tau*.

TAU, in *Ichthyology*, a species of *Gadus*; which see.

TAUA, in *Ancient Geography*, a town of Egypt, and the metropolis of the nome Phthempthus. Ptol. and Steph. Byz.—Also, a town of Asia, between Namaris and Augara. Ptol.—Also, a gulf of the isle of Albion, on the south-eastern coast. This estuary is the firth of Tay.

TAUA, in *Geography*, a town of Egypt; 12 miles S. of Denutar.

TAVACCARÆ, in the *Materia Medica*, the name by which many authors call the *coccus Maldivia*, or Maldive nut.

TAUAG, in *Geography*, a town of Persia, in Farsistan; 39 miles S.E. of Bender-Rigk.

TAVAI, an island in the Indian sea, near the coast of Siam, about 20 miles long and 3 broad. N. lat. 13°. E. long. 97° 52'.

TAVAI, a town of Asia, in Lower Siam; 148 miles S. of Martaban. N. lat. 14° 10'. E. long. 98° 12'.

TAVAI Point, the extreme point of a tract of land on the coast of Lower Siam. N. lat. 13° 40'. E. long. 98°.

TAVAI or *Tovy Poenamoo*, the southernmost of the two islands into which New Zealand is divided by Cook's strait, which is for the most part mountainous and apparently barren, and in this respect of a less favourable aspect than the other island, or *Eabeinomauwe*; which see. The straits, which are about four or five leagues broad, were discovered by Capt. Cook at the close of the year 1769. The islands are situated between the latitudes of 34° and 48° S., and between the longitudes of 181° and 194° W. Tavai-Poenamoo is said to be 500 miles long from S.W. to N.E., and from 55 to 140 broad. See *NEW ZEALAND*.

TAVANAGUROY, a town of Hindoostan, in Myfore; 13 miles W. of Colar.

TAVARADO, a town of Portugal, in the province of Beira; 7 miles W.S.W. of Montemor o Velho.

TAVARES, a town of Portugal, in the province of Beira; 13 miles E. of Viseu.

TAVASTLAND, a province of Sweden, bounded on the N. by East Bothnia, on the E. by Savolax or the government of Kuopio, and the Russian government of Viborg, on the S. by Nyland, and on the W. by the government of Abo, or Finland Proper; about 150 miles in length from N. to S., and from 35 to 100 in breadth from E. to W. The country is very fertile, and consists of fine plains, watered by a great number of rivers and lakes, which abound in fish. It is diversified with arable and meadow lands; so that with respect to these natural advantages, it may not only be looked upon as the best part of Finland,

but is indeed scarcely surpassed in those particulars by any province in Sweden. It is likewise stored with cattle, fish, and all sorts of game. But notwithstanding this country is so fertile, it is far from being well cultivated; and, consequently, the peasants are generally very poor. Sometimes, indeed, the corn is much damaged by keen and unexpected frosty nights. The northern part of Tavastland is more mountainous and woody than the southern. In the morasses and uncultivated sandy wilds, a ferruginous earth is dug up, from which the Eisenfand ertz, or iron sandy ore, as it is called, is prepared. The inhabitants subsist by agriculture, grazing, and breeding of cattle, and some of them are employed in the fisheries. They also traffic in corn, peas, beans, flax, hemp, dried fish, cattle, leather, tallow, butter, lime, the bark of trees, &c.

TAVASTHUS, or KRONEBERG, a town of Sweden, and principal place in the province of Tavastland, built in the year 1650, on a pleasant spot, by count Pehr Brahe, and endowed with considerable privileges. In 1713, this town was taken by the Russians; and in the last war between them and the Swedes, it was laid in ashes. The castle, which, exclusive of the town, is properly called "Tavastheus," or "Tavasteborg," is well fortified, and serves for an arsenal and royal magazine; 80 miles N.N.E. of Abo. N. lat. 61° 1'. E. long. 24° 15'.

TAVAVIS, or THAOUAOUIS, a town of Asia, in Grand Bucharía; 15 miles N.E. of Bucharía.

TAUBATE, a town of Brasil; 130 miles W. of Rio Janeiro.

TAUBE, FREDERICK WILLIAM Von, LL.D., in *Bio-graphy*, was the son of Dr. Taube, physician to queen Caroline, consort of George II., and born in London in the year 1728. After the queen's death, the father settled at Zelle, where he died in 1742; and in the following year his son was entered at the university of Gottingen. Here he assiduously applied to the study of jurisprudence; and before he left the university, being in his 19th year, he published a dissertation "De Differentiis Juris civilis a jure Naturæ," intended to prove that the principles of the Roman, Canon, and German law were contrary to the law of nature, and inconsistent with the rights of man. When he quitted the university, in the year 1747, he travelled into foreign countries, and particularly through some parts of Africa and America. On his return he practised the law at Gottingen, but finding, in consequence of some displeasure which he had excited by the freedom with which he censured the tediousness of law-suits, that he had no prospect of advancement, he removed to Vienna in 1756, where he obtained some preferment in the army. Soon after an engagement in which he was wounded during the seven years' war, he abandoned Lutheranism, and embraced the tenets of the church of Rome, hoping thus to rise in the Imperial service. Having given proof of his talents and fidelity in an honourable office, which he occupied, and being acquainted with the English language, he was appointed secretary to the Imperial ambassador at the court of London, and repaired thither in October, 1763. Here he married a niece of the celebrated Dean Tucker, with whom he lived in habits of intimacy and friendship. In 1766 he returned to Vienna, and was appointed secretary to the council of trade, which was an office of great fatigue, on account of the journeys which it obliged him to take to distant places. When this college was dissolved, in 1776, he retired to Brussels. Having fulfilled another confidential commission with which he was entrusted, he returned from Belgrade to Vienna in 1777, and was ennobled by the emperor, and appointed a member of the government of Lower Austria. His health being

being much impaired, required an attention which it did not suit his inclination or occupation to give it: his disorder, which was an inflammation of the lungs, increased, and terminated his life in June, 1778, in the 50th year of his age. He was justly honoured for his integrity, his zeal to serve his friends, and his liberality. His literary labours evince the extent of his learning and researches. His principal works are the tract already mentioned; "Thoughts on the present State of our Colonies in America, on their Behaviour to the Mother-Country, and on the true Interest of the Nation in regard of the Colonies," London, 1766; "Historical and Political Sketch of the present State of the English Manufactures, Trade, Navigation, and Colonies, &c." 1774, 8vo.; "History of the English Trade, &c. from the earliest Periods till the Year 1776, with an authentic Account of the true Causes of the present War with North America," 1776, 8vo.; "J. J. Schetzen's Elements of Geography, improved and enlarged," 1786, 8vo.; "Historical and Geographical Description of the Kingdom of Sclavonia and Duchy of Symria, &c. in three parts," 1777, 1778; "An Account of various New Discoveries, made in 1776 and 1777, in Sclavonia, &c. &c." Leipzig, 1777, 4to. He contributed also, between the years 1773 and 1778, to Buching's periodical publications. He also communicated to the Royal Society of London "A short Account of a particular Kind of Torpedo found in the River Danube, with several Experiments on that Fish," published in the Phil. Trans. for 1775. Gen. Biog.

TAUBE, in *Geography*, a river of Westphalia, which runs into the Aland, near Seehausen.

TAUBER, a river of Germany, which rises about eight miles S. of Rotenburg, in Franconia, and runs into the Maine at Wertheim.

TAUBER See, a lake of Bavaria; 6 miles W. of Berchtesgaden.

TAUCAEL, or TUCHEL, a town of Prussia Pomerania. This town was taken and burned, in the year 1320, by the Teutonic knights, and afterwards rebuilt; 44 miles S.S.W. of Dantzic.

TAUCHA, a town of Saxony, in the circle of Leipzig. This town was built in the year 1221, by Albert, archbishop of Magdeburg, afterwards rebuilt, and in the year 1431 destroyed by the Bohemians and Hussites, when most of the inhabitants removed to Leipzig; 6 miles N.E. of Leipzig. N. lat. 51° 22'. E. long. 12° 30'.

TAUCHIRÆ, in *Ancient Geography*, a town of Africa, in Libya, belonging to the territory of Barcé, according to Herodotus, afterwards called Arsinoe. M. D'Anville supposes that it is the present Teukéra.

TAVDA, in *Geography*, a river of Russia, which rises in Pelim lake, and runs into the Tobol, 40 miles S. of Tobolsk.

TAUDECONDA, a town of Hindoostan, in Golconda; 25 miles S.W. of Warangole.—Also, a town of Hindoostan, in Dindigul; 7 miles N. of Dindigul.

TAUDENNY, or TUDENNY, a Moorish and Negro town or village, on the borders of the Desert in Africa; at which place are large ponds or beds of salt, which both the Moors and Negroes purchase, as well as dates and fig-trees of a large size. The salt-beds are about 5 or 6 feet deep, and from 20 to 30 yards in circumference. The salt comes up in red lumps mixed with earth, and part of it is red; 270 miles N.N.W. of Tombuctoo. N. lat. 21° 15'. W. long. 1° 25'.

TAUDOON, a town of Hindoostan, in Lahore; 34 miles S.S.E. of Nagercote.

TAVE, a river of France, which runs into the Rhone, about 6 miles below Loudon.

TAVE, or Taff, a river of Wales, which runs into the sea, near Llaugharn.—Also, a river, which rises in two streams in the southern part of Brecknockshire, and runs into the Severn below Cardiff.

TAVERA, a town of Corfica, 18 miles N.N.E. of Ajazzo.

TAVERA di Orta, a town of Naples, in Capitanata; 14 miles S.S.W. of Ascoli.

TAVERNA, a town of Naples, in Calabria Ultra, formerly the see of a bishop, transferred to Catanzaro; 15 miles N. of Squillace.

TAVERNER, JOHN, in *Biography*, an eminent musician, who flourished in the early part of the 16th century. He is often mentioned by Morley among our early contrapuntists, and by Anthony Wood, as having begun his career by being organist of Boston, in Lincolnshire. At the establishment of Cardinal college, now Christ-church, Oxford, by cardinal Wolsey, he was appointed organist there; but narrowly escaped martyrdom for heresy, having held frequent conversations with some Lutherans on the abuses of religion. They were all imprisoned in a deep cave under the college, used for the keeping of salt-fish, of which the stench occasioned the death of some of them, and some were burnt in Smithfield.

Taverner had not gone such lengths as many of the fraternity; the suspicions against him were founded merely on his having hidden some heretical books under the boards of the school where he taught, for which reason, and on account of his professional eminence, the cardinal excused him, saying "he was but a musician," and so he escaped.

A set of books containing masses and motets to Latin words, some of which were composed in the time of Henry VII., and all before the Reformation, is preserved in the music-school at Oxford. These volumes contain compositions by John Taverner, Dr. Fayrfax, Avery Burton, John Marbec, William Kafar, Hugh Ashton, John Norman, John Sheppard, and Dr. Tye. The pieces by the three or four last are entered in a more modern hand, with different characters, and paler ink. The chief parts of the compositions are transcribed in a large, distinct, and fine hand and character; but bars not having been yet introduced, and being all *ad longam, alla breve*, or in *tempo di Capella*, the ligatures, prolations, and moods, render these books extremely difficult to read, or transcribe in score. However, by dint of meditation and perseverance, we arranged the parts under each other, of several movements by all these founders of our church music, particularly John Taverner, Dr. Fayrfax, and Dr. Tye; having scored an entire mass by each of them: as they are the most ancient and eminent of these old masters, in whose compositions the style is grave, and harmony, in general, unexceptionable, if tried by such rules as were established during their time; but with respect to invention, air, and accent, the two first are totally deficient.

The compositions, however, of these early English masters, have an appearance of national originality, free from all imitation of the choral productions of the continent. Few of the arts of canon, inversion, augmentation, or diminution, were as yet practised by them: short points of imitation are sometimes discoverable, but they seem more the effects of chance than design: and to characterise the chief of these composers in the order they have been named; Taverner and Fayrfax have but little design and no melody in their compositions; and it seems as if they should not

have

have been ranked, as they are by Morley, with those of a much higher class, at a later period.

We can venture to give a character of Taverner, from an actual survey of his principal works which have been preserved, and which we have taken the pains to score. This author is in general very fond of slow notes, so that all his pieces which we have seen, are *ad longam*, or, at quickest, *alla breve*. Long notes in vocal music, unless they are to display a very fine voice, have little meaning, and are wholly destructive of poetry and accent; but our old composers have no scruples of that kind; and being as great enemies to *short* syllables, as to *short* notes, exercised the lungs of a singer as frequently upon one as the other.

As the first essays at harmony were made in extemporary discant, upon a plain-song, so in written counterpoint, it was long a favourite and useful exercise, to build the several parts of a movement upon some favourite chant, making it the ground-work of the composition. And this custom answered several purposes: it excited ingenuity in the construction of the parts; it regulated and restrained the modulation within the ecclesiastical limits; and as the plain-song had been long used in the church, by the priests and people, it was still easy for the musical members of the congregation, to join the chorus in singing this simple and essential part, while the choristers and choirmen by profession, performed the new and more difficult melodies, which had been superadded to it by the composer. The first reformers, or at least their followers, who were perhaps no great musicians, wished to banish every species of art from the church; and either retaining small portions of ancient chants, or making melodies, in the same plain and simple style, for their hymns and psalms, threw aside all figurative harmony and florid counterpoint; and sung in notes of equal duration, and generally in mere unison, those tunes which are still retained by the Calvinists, and in most of the reformed churches of Christendom. At the latter end of the fifteenth, and during the whole of the sixteenth century, as some chant or tune was the foundation upon which the harmony of almost every movement of a mass or motet was built, the additional parts were the superior, medius, counter-tenor, tenor, to which was given the plain-song in square black notes, of equal lengths to semibreves in *alla breve* time, and basses. The close or final movement of one of these masses is inserted in Burney's General History of Music, vol. ii. p. 557.

TAVERNES, in *Geography*, a town of France, and chief place of a canton, in the department of the Var, and district of Brignolles. The place contains 1536, and the canton 4529 inhabitants, on a territory of 280 kilometres, and 9 communes; 3 miles N. of Barjols.

TAVERNIER, JOHN BAPTIST, in *Biography*, a distinguished traveller, was the son of a native of Antwerp, and born at Paris in the year 1605. The frequent inspection of the maps and charts sold by his father, inspired him with a passion for travelling; so that at the age of twenty-two he had made tours through France, England, the Low Countries, Germany, Switzerland, Poland, Hungary, and Italy. In his business as a jeweller he was eminently skillful; and he employed 40 years in six journeys in Turkey, Persia, and the East Indies, by all the practicable routes. Having acquired great wealth, on his return from his sixth journey in 1668, he determined as a Protestant to live under a free government; and, with this view, purchased the barony of Aubonne, near the lake of Geneva. But having suffered very considerable loss of property by the misconduct of a nephew, he sold his barony in 1687, and commenced a se-

venth journey, which terminated his life at Moscow in 1689, at the age of 84. Destitute of talents for writing, he employed Sam. Chappuzeau of Geneva to arrange his memoirs, which is said to have been no easy task. The fruit of this labour was given to the public in two volumes, describing his six journeys, in 1679; and another was added in 1681, by La Chapelle, containing an account of Japan and Tonquin, with a history of the colony of the Dutch in the East Indies. These memoirs of Tavernier, notwithstanding reflections on his veracity, and charges of plagiarism, have been often cited as authority by later writers. Gibbon represents him as "the jeweller who saw so much and so well." Bayle. Moreri. Gen. Biog.

TAVERNIER Key, in *Geography*, a small island on the north coast of Cuba, near Tortuga.

TAVERNY, a town of France, in the department of the Seine and Oise; 6 miles E. of Pontoise.

TAVETCH, a community which, with that of Dientis, forms one of the high jurisdictions of the Grey League in Switzerland. These two communities occupy the western extremity of the valley of Sopra Selva, stretching as far as the confines of Uri. Tavetch is a pleasant valley, lying at the foot of the Alps, which separate the Grisons from the canton of Uri. The villages are numerous, consisting of scattered cottages chiefly constructed of wood. This valley produces pasture, hemp, and flax, and a small quantity of rye and barley. The trees are chiefly firs and pines, and their number gradually diminishes towards the extremity of the vale.

TAVETSCH, a town of the country of the Grisons; 13 miles from Ilantz, the capital.—Also, a mountain of the same country; 5 miles S.W. of Ilantz.

TAUFFERS, a town of the county of Tyrol; 6 miles S.S.W. of Glurentz.

TAUGHT, or TAUT, *Tight*, in the *Sea Language*, denotes the state of being extended or stretched out. Thus they say, *set taught* the shrouds, the stays, or any other ropes, when they are too slack and loose.

TAVI, in *Geography*, a town of Sicily, in the valley of Noto; 7 miles N.E. of Castro Giovanni.

TAVIANO, a town of Naples, in the province of Otranto; 11 miles W.N.W. of Alesano.

TAUJEPUR, a town of Bengal; 60 miles S.S.W. of Calcutta. N. lat. 21° 52'. E. long. 87° 45'.—Also, a town of Bengal; 32 miles E. of Purneah. N. lat. 25° 48'. E. long. 88° 11'.—Also, a town of Hindoostan, in Bahar; 15 miles N. of Chuprah. N. lat. 26° 2'. E. long. 84° 50'.

TAVIGNANO, a river of Corsica, which runs into the sea, 15 miles S. of Cervione.

TAULLA, a town of Arabia, in the province of Yemen; 24 miles W. of Tana.

TAUILE, a town of Egypt, on the Nile; 2 miles N. of Mansora.

TAVIRA, or TAVILA, a sea-port town of Portugal, in the province of Algarve, surrounded with walls, and defended by a castle; the harbour is protected by two forts. It contains two churches, an hospital, five convents, and about 5000 inhabitants; 111 miles S.S.E. of Lisbon. N. lat. 37° 7'. W. long. 7° 35'.

TAVISTOCK, an ancient borough and market-town, in a hundred of the same name, in the county of Devon, England, is situated on the banks of the river Tavy, 34 miles W.S.W. from Exeter, and 206 miles in the same bearing from London. Its origin and growth seem to have arisen from the foundation and establishment of a magnificent abbey in the tenth century, by Ordgar, earl of Devon, and his

his son Ordulph. Within thirty years after its foundation, this abbey was burnt by the Danes, but was soon afterwards rebuilt, and became more flourishing than before. By a charter granted by Henry I., it appears that he bestowed "the jurisdiction, and the whole hundred of Tavistock," upon the abbey, together with the privilege of a weekly market, and a three-days' fair. This charter is recited and confirmed by one granted 21 Edw. III. The riches of the abbey progressively increased; and Richard Barham, the thirty-fifth abbot, obtained from Henry VIII. the privilege of sitting in the house of peers, or, in other words, was mitred. His patent was dated January 23d, 1513; but the honour continued only till the year 1539, when John Peryn, the thirty-sixth abbot, surrendered the abbey to the crown, and had a pension of 100*l.* per annum. The possessions of the abbey, with the borough and town of Tavistock, were given by the king to John, lord Russell, whose descendant, the present duke of Bedford, is now proprietor. Various fragments of the abbey still remain, but are, for the most part, incorporated with other buildings. The abbey church is described by Leland as 126 yards in length; the cloisters as extensive; and the chapter-house as a most magnificent structure: but all these have long since been completely demolished. Several buildings, that seem to have belonged to the abbey, are now used for warehouses; and adjoining to the principal inn is a large, handsome, arched gateway, ornamented with lofty pinnacles, apparently of the time of Henry VI. The town of Tavistock is large and populous; but the streets are narrow, and indifferently paved; and many of the houses have an appearance of age. The river is here crossed by two bridges, and after storms of rain, by flowing over various ledges and masses of rock, presents a very tumultuous spectacle. The church is a spacious edifice, consisting of four aisles, a chancel, and a tower at the west end, raised on arches. Within the church are preserved some human bones of a gigantic size, which were found in a stone coffin, dug out of the ruins of the abbey, and are said by tradition to be those of Ordulph, whom William of Malmesbury represents of such immense stature, that he could stride over rivers ten feet wide! Tavistock is a borough by prescription, and has sent two members to parliament from the 23d year of Edward I. The right of election is in the freeholders resident in the borough. The town is one of the stannaries of Devonshire, but does not appear to have been incorporated. It is governed by a portreeve, who is elected annually at the court of the lord of the manor. The population of the parish, according to the return of the year 1811, amounted to 4723; the number of houses to 514. Many of the inhabitants are employed in the manufacture of serges for the East India Company. Five fairs are held annually, and a weekly market on Saturdays. An institution for the study of Saxon literature existed in Tavistock at a very early period, and lectures were read in that language in a building purposely appropriated, and called the Saxon school. These lectures were discontinued about the time of the reformation. Several of the abbots were learned men; and the encouragement they gave to literature is evident, by the establishment of a printing-press in the abbey within a few years of the time when the art was brought into England. Among the books that issued from this press was Walton's translation of "Boethius de Consolatione," "emprinted in the exempte Monastery of Tavestoke in Denshyre, by me Dan Thomas Rychard, monke of the said Monastery," 1525, 4to.; and the "Confirmation of the Tynners Charter," 26th of Henry VIII., 16 leaves, 4to. Bishop Gibson also mentions a Saxon Grammar as having been printed here about the commence-

ment of the civil wars; but this assertion is supposed by other antiquaries to be unfounded.

Among the more eminent natives of Tavistock was Sir Francis Drake, one of the most distinguished seamen that Britain ever produced, and the first Englishman that circum-navigated the globe.

Morwell-house, about three miles from Tavistock, was the hunting-seat of the abbots of Tavistock; and from its situation near Morvel-down, and the woods on the banks of the Tamar, was well adapted for this purpose. Its form is quadrangular, with a large arched gateway in front, ornamented in a similar manner to those of the abbey. The vaulted ceiling of this entrance has several coats of arms sculptured in moor-stone. At a little distance is Morwell-rock, which rises almost perpendicularly to an immense height from the bed of the Tamar.

About four miles north of Tavistock is Bren-Tor, a vast mass of craggy rock, which shoots up from the road between Tavistock and Lydford, and becomes a very conspicuous sea-mark to mariners in the British Channel, though more than 20 miles distant. The summit is frequently enveloped in clouds; but in fair weather commands an extensive prospect, and the ships in Plymouth harbour may be distinctly seen from its summit. Near the top is the parish church of the little village of Brent, which, like most of the churches in similar situations, is dedicated to St. Michael. On Dartmoor, about three miles east of Tavistock, are several masses of rock, and also the remains of Druidical circles and avenues.—*Beauties of England and Wales*, vol. iv. Devonshire, by J. Britton and E. W. Brayley.

TAVIUM, or TAVIA, in *Ancient Geography*, a town of Asia, in Galatia, and capital of the Trocmi, according to Ptolemy, Strabo, and Pliny.

TAULACUM, in *Natural History*, a name given by the people of the East Indies to a species of orpiment, which is very common with them.

It is of a dirty yellow colour, and is composed partly of an irregular mass, partly of fine flakes, like scales of fishes. These are of the best colour. The whole mass, on being exposed to the fire, burns, and emits copious fumes; but it does not melt readily. After it has been several times calcined, the Indians give it internally in intermittent fevers, with safety and success. Woodw. *Catal. Foss.* vol. i. p. 24.

TAULE', in *Geography*, a town of France, in the department of the Finisterre; 3 miles N.W. of Morlaix.

TAULE, a town of Hindoostan, in Mysore; 47 miles E. of Seringapatam.

TAULIGNAN, a town of France, in the department of the Drôme; 12 miles S.E. of Montelimart.

TAUMACO, a town of Greece, in the province of Theffaly; 18 miles N.W. of Zeiton.

TAUMAGO, an island in the Pacific ocean, discovered by Quiros, in 1606; about 24 or 25 miles in circumference. The island abounded with bananas, cocoa-trees, and palms: it produces also sugar-canes, and many kinds of nutritious roots. The fleet here obtained, without difficulty, refreshments, water, and wood, of which it stood in great need. The Spaniards lived on good terms with the natives, who were eager to procure them all the assistance that their island afforded; nor was peace infringed till the very moment of their departure. Thinking that it would be of service in the remainder of their voyage, to have some Indians on board, who might act as guides or interpreters, the Spaniards seized four whom they carried on board by force. Their chief was soon informed of it, and came to demand them in the most earnest manner; but they were refused,

and war was instantly declared. A fleet of canoes came out to attack the Spanish ships, which their fire-arms quickly dispersed, and would totally have destroyed, had not these brave islanders, with all their courage, been sensible of their inferiority. S. lat. 10°. E. long. 169° 25'.

TAUME, a river of England, which rises in the county of York, and runs into the Mersey, in Lancashire, opposite Stockport.

TAUNA, a town of Egypt, on the Bahir Joseph, or Canal of Joseph, which forms a communication between the Nile and the Birket el Kerum; 5 miles S.W. of Alh-munein.

TAUNDA, a town of Hindooostan, in Oude; 50 miles S.E. of Fyzabad. N. lat. 26° 32'. E. long. 82° 53'.

TAUNNA, a town of Hindooostan, in Oude; 30 miles W. of Lucknow.

TAUNT, a sea-term, signifying high or tall. When the masts of a ship are too tall for her, the sailors say, she is *taunt-masted*.

TAUNTON, in *Geography*, a considerable market-town and borough, in the hundred of Taunton-Dean, county of Somerset, England, is situated on the high road between Bath and Exeter, 52 miles S.W. from the former city, 32 miles N.E. from the latter, and 144 W. by S. from London. It was anciently called Thonodunum, or the Town of the Tone, by which river it is watered. Taunton is unquestionably a place of remote antiquity: from the discovery of coins and other relics, there is reason to suppose it was not unknown to the Romans; but it is certain it was of great note in the time of the Saxons. For Ina, a West-Saxon monarch, built a castle here for his residence in the year 700, which was destroyed in 722 by his queen Ethelburga, who prevailed on him to resign the crown, and retire to a monastery. A new castle, on the site of the former, was erected by William Giffard, bishop of Winchester in the time of Henry I. By various documents of the bishops of that see, dated Taunton castle, it seems to have been a place of their frequent residence. In 1495 the whole building was repaired, and an embattled gateway built by bishop Thomas Langton. Though the building has been much modernized, this gateway still remains. Considerable improvements were made in 1577, by bishop Robert Horn, who likewise built the great hall as it now stands, in which the assizes, county sessions, and bishop's courts are held: it is 110 feet in length, 30 in width, and 20 in height. The other apartments are applied to various public uses. The whole castle occupied a front of 195 feet, with a circular tower at each end, of which only one is now remaining. Taunton had a distinguished share in the various civil commotions of this kingdom: in the contests of the Saxon kings; in the civil wars between the houses of York and Lancaster; and in the insurrection in favour of Perkin Warbeck, in Henry VII.'s reign. In the civil wars of Charles I., it became an object of vigorous struggle between the royal and parliamentary forces which should possess its fortrefs, it being considered as the key to the west of England. It was also deeply involved in the rebellion of the duke of Monmouth, who here assumed the title of king, and was publicly proclaimed.

The town of Taunton, in point of size, buildings, and respectability of inhabitants, may vie with most cities. It contains two parishes, extends nearly a mile from east to west, and consists of four principal streets, which are well built, and of commodious width. Though ancient and populous, it was not incorporated till the reign of Charles I., 1627. It did not long enjoy this privilege; for Charles II., on his restoration, out of resentment for the town's adherence

to the parliament against his father, deprived it of its charter. It continued disfranchised 17 years, when the king granted it a new charter. The corporation consists of a mayor, recorder, a justice of the peace, two aldermen, ten capital, and ten inferior burgesses. The justice is always the last mayor, who, with the two aldermen, are annually elected out of the capital burgesses; and the vacancies occasioned by this election are filled up from the inferior members of the corporation. The officers are a town-clerk, two sergeants at mace, a bell-man, and a beadle. There are acting under the mayor, and sworn in by him, two constables and six tything-men or petty constables, who, with two port-reves and two bailiffs, are annually chosen by a jury, and are, properly speaking, the officers of the bishop of Winchester, in whose court they are elected. The mayor's officers cannot arrest within the borough; and there being no prison, except a kind of town-bridewell called the Nook, debtors are sent to the county gaol at Ilchester. Though the town has for ages been flourishing, and of great importance in the county, yet the corporation has neither land, houses, nor joint stock in money; their charter excluding them from such possessions.

Taunton is an ancient borough by prescription, and has returned two members to parliament from the year 1294, 23 Edward I. The right of election is vested in a description of people called pot-wablers, or pot-wabloners. These are all such inhabitants as reside within the borough, and boil their own pots, provided they are not paupers, and have not received relief from the fund of any charity within a year. The number of voters is estimated at about 500. The bounds of the borough, to which the right of election is limited, are small in proportion to the town, comprehending only a part of the parish of St. Mary Magdalen. The principal article of trade in Taunton is the woollen manufacture, which has flourished to a great extent almost ever since its introduction into England by the famous John Kempe, the first manufactory being established so early as the year 1336. Upwards of one thousand looms are said to have been employed at one time; but the trade is now greatly reduced, and the population decreased: houses in the suburbs have fallen to ruin, and have been destroyed. A large silk manufactory was established in the year 1780. Two large markets are held on Wednesday and Saturday, and here are two annual fairs. By the population report of the year 1811, Taunton was stated to contain 1371 houses, and 6997 inhabitants.

The edifices for religious worship in this town are two parish churches, and five dissenting meeting-houses. The church of St. Mary Magdalen is a spacious beautiful structure, with a lofty and strong tower of excellent workmanship, of the florid style, having four stately pinnacles thirty-two feet high, making the whole height 153 feet. This tower has thirteen handsome windows, with a variety of curious prominent ornaments, that give the whole an air of magnificence, united to a delicate elegance, not to be equalled in the county, nor perhaps in the kingdom. It was probably erected by Henry VII., who, when he came to the crown, rebuilt many of the churches in Somersetshire, as a reward of the attachment of the county to the Lancastrian party. The inside of the church is answerable to the exterior, and makes a grand appearance. Its curious roof is supported by twenty-four pillars, in four rows, dividing it into five aisles and a chancel. There are forty-four windows, some of which have painted glass. The other church, St. James's, though every way inferior to the former, is a strong, plain, ancient structure, supposed to have been built in the 13th century. The meeting-houses are St. Paul's, and the new meet-

ing,

ing, for Protestant dissenters; one for Baptists, one for Quakers, and one for Wesleyan Methodists. The buildings for charitable purposes are, a free grammar-school, founded by Richard Fox, bishop of Winchester, about the year 1500; two large and well endowed alms-houses, founded in the 17th century, by Mr. Robert Graye and Mr. Richard Huish; two other alms-houses, on a smaller scale; two work-houses; and an hospital, the most capital of its kind in the county: it is a square structure, 90 feet on a side; contrived to admit through every part a free circulation of fresh air; and forming on the whole a commodious receptacle for the diseased. The first corner-stone was laid by lord North in 1772, and the building was completed in 1774. In the centre of the town is a spacious building, erected in 1772, under the sanction of an act of parliament; the lower part is the market-house, over which is the town-hall, where the borough sessions are held.

On the east part of the town was a priory for Black canons, founded in 1127, by bishop Giffard: at the dissolution, it was granted to Matthew Colehurst. A leper-house was also founded about the year 1280, by Thomas Lambritz; and a house of White or Carmelite friars, in 1322, by Walter de Meryet. Both these houses are supposed to have been private property previous to the dissolution.—Collinson's History of Somersetshire, vol. iii. Toulmin's History of the Town of Taunton; 4to. 1791. Maton's Observations on the Western Counties of England, vol. ii. 3vo. 1797.

TAUNTON, a river of Massachusetts, which runs into the sea at Rhode island, N. lat. $41^{\circ} 24'$. W. long. $71^{\circ} 10'$.—Also, a town of Massachusetts; 29 miles S. of Boston. N. lat. $41^{\circ} 48'$. W. long. $71^{\circ} 2'$.—Also, a river of America, in the province of Maine, which runs into the sea near New Bristol.

TAUNTON-DEAN, a valley of England, extending about thirty miles in length, in the county of Somerset, of fertility and produce equal to almost any in the kingdom. It takes its name from Taunton, the principal town.

TAVOLADOTO, a small island near the east coast of Sardinia. N. lat. $40^{\circ} 54'$. E. long. $9^{\circ} 5'$.

TAVOLARA, a small island near the east coast of Sardinia. N. lat. $40^{\circ} 52'$. E. long. $10^{\circ} 5'$.

TAVORA, a river of Portugal, which runs into the Duero, 5 miles N.E. of Lamego.—Also, a town of Portugal, in the province of Beira; 6 miles E. of Lamego.

TAVOYVOVEL, a small island near the east coast of Lewis. N. lat. $58^{\circ} 6'$. W. long. $6^{\circ} 29'$.

TAURAGUR, a town of Hindoostan, in Lahore; 24 miles W.N.W. of Nogaroot.

TAURASI, a town of Naples, in Principato Ultra; 12 miles S.E. of Benevento.

TAURASIA, in *Ancient Geography*, a town of Italy, in Gallia Transpadana.

TAURAT, in *Geography*, a town of the island of Cuba; 38 miles N.N.E. of St. Jago.

TAUREA, among the Romans, a punishment inflicted by whipping with scourges made of bulls' hides.

TAUREAU, in *Geography*, an island on the French coast, with a fort to defend the harbour of Morlaix.

TAUREE, a town of Bengal; 35 miles S.S.E. of Ghidore.

TAURESIIUM, in *Ancient Geography*, a town of European Dardania, on the other side of the territory of Duras; the birth-place of Justinian, who founded here a magnificent town, called after his own name.

TAURI *liberi libertas*.—In some ancient charters, *taurus liber* signifies a common bull kept for all tenants within such

a manor, or liberty.—“Cum libertate faldiz, liberi tauri, et liberi apri, &c.” See *Free BULL*.

TAURI, in *Ancient Geography*, a people of Sarmatia, in the vicinity of Scythia. According to Herodotus, these people had a custom of sacrificing to Iphigenia, the daughter of Agamemnon, the strangers whom chance threw on their coats, and also the Greeks who fell into their hands.

TAURIA, *Ταυρία*, in *Antiquity*, a festival in honour of Neptune. Pot. Archæol. tom. i. p. 432.

TAURIA, in *Ancient Geography*, an island of the Mediterranean sea, between New Carthage and Cæsarea of Mauritania. Anton. Itin.

TAURIANA, a town of Italy, in Brutium.

TAURICA CHERSONESUS. See *CHERSONESUS Taurica* and *CRIMEA*.

TAURIDA, TAURICHESKAIA, or *province of Tauris*, in *Geography*, a province of Russia, being part of the government of Catherinenslaf or Ecaterrinenslaf or Ekaterinofslav, bounded on the N. by the rivers Dnieper and the Konksija, on the W. and S. by the Black sea, and on the E. by the sea of Azoph. This fertile peninsula, which is the great mart of commerce in the Black sea, was colonized for the purposes of trade by the Greeks, Romans, Genoese, occupied by the Turks under Mahomet II., and governed by the khan of the Tartars, a vassal to the Porte. On the peace of Kniardi, in 1774, it was declared an independent sovereignty, taken possession of by Catharine II. on the abdication of the khan Sahin Gerai, in 1783, and confirmed to Russia by the Porte in the same year by the treaty of Constantinople. The empress revived several of the ancient Greek names. M. Pallas has exhibited an animated and delightful picture of this province in his account of a journey made in 1794, for which we refer to Tooke's Russia, vol. i. For a farther account of it, see *CRIMEA*. See also *RUSSIA*.

TAURIDA, *Mountains of*, are extended and lofty, forming the southern side of the province, and the shore of the Euxine sea. The range extends from Theodosia in a straight line westwards, quite up to Balbeck. At Karafobafar two towering pinnacles shoot up, and at Akmelchat a very elevated one, called Aktau. The smaller mountains stand distinct and scattered. It is very probable that this range is partly a continuation of the Caucasian, and partly of the Carpathian mountains; and that these two principal chains are connected by it: which also seems apparent from the nature and qualities of the mountains opposite to those of Taurida, which extend beyond the Danube, through Bulgaria, and are called Pulkanian. The greater part of these mountains of Taurida consists of chalk-masses with petrifications, and many beds of sand and marle, and chalk-hills with flints. Hence it is presumed that they are not to be classed with the original, but only with the alluvial or deposited mountains. A part of them is thought to owe its origin even to the subterranean fires. Whether this be the case or not, it is said that lead, copper, and iron ores are found in them, as well as jasper, agate, and mountain crystal. They are very rich in lime-stone, marble, slate, sand-stone, coals, naphtha, and common salt. The isle of Taman consists merely of beds of sand and marle, without lime-stone. The height of the Taurida mountains is moderate; and they are in a great degree destitute of forests. The trees that grow upon them are those of the richest foliage, such as oak, beech, chestnut, &c. But what they want in wood is made up very amply by the rich and beautiful herbs of the vallies. The rivers that take their rise from these mountains are the Alma, Katsha, Kabarda, Salgyr, Karuffu, and many lesser streams, that form pleasing natural cascades.

TAURILIA, among the Romans, games in honour of the infernal gods. They were otherwise called *ludi taurii*.

TAURINIA, in *Ancient Geography*, a town of European Sarmatia, in the peninsula called "Curfus Achillis." Steph. Byz.

TAURIS, in *Geography*. See **TABREEZ**.

TAURISCI, in *Ancient Geography*, a Celtic people, who were established along the Danube. They were separated from the Scordisci by a mountain called by Pliny Mons Claudius.

TAURO, a town of European Sarmatia, in the peninsula of "Curfus Achillis." Suidas.

TAUROBOLIUM, or **TAUROBOLION**, among the *Ancients*, sacrifices of bulls, which were offered to Cybele, the mother of the gods, to render thanks to the goddess of the earth, for her teaching men the art to tame those animals, and fit them for labour.

The Taurobolium was a kind of sacrifice of expiation and purification; of which no trace occurs before the reign of Antonine, and which seems to have terminated under Honorius and Theodosius the younger. It was principally employed in the consecration of the priests of Cybele.

TAVRO-CASTRO, in *Geography*, a town of Greece, in Livadia; 20 miles N.N.E. of Athens.

TAUROCINIUM, in *Ancient Geography*, a river of Italy, in Magna Græcia; and the people who lived upon its banks in the vicinity of the town of Rhegium, were called Taurocini.

TAUROCOLLA, *Bull-Glue*, a sort of glue much used among the ancients in work that required strength, being accounted far stronger than any other kind. It was made by boiling down the ears and genital parts of a bull in water.

TAUROENTUM, in *Ancient Geography*, a colony founded by the ancient Marfeilloise on the sea-shore, to the right of the entrance into the bay of Ciotat.

TAUROGEN, in *Geography*, a town of Samogitia; 30 miles S.W. of Roshenne.

TAUROMENIUM, in *Ancient Geography*, a town of Sicily. See **TAORMINA**.

TAUROPOLIA, in *Antiquity*, feasts celebrated in honour of Diana and Apollo, in the Icarian isles, viz. those of the Archipelago and of the Ægean sea.

TAUROPOLIAN, in *Ancient Geography*, the name of a temple situated in the isle of Samos; dedicated to Artemis, or Diana.—Also, a temple dedicated to Diana, in the isle of Icaria. Strabo.

TAUROPOLIS, a town of Asia Minor, in Caria.

TAURUS, in *Astronomy*, the *Bull*, one of the twelve signs of the zodiac, and the second in order.

The stars in the constellation Taurus, in Ptolemy's catalogue are 44; in Tycho's catalogue, 43; in Hevelius's catalogue, 51; in the Britannic catalogue, 141. See **CONSTELLATION**.

TAURUS, in *Ancient Geography*, a name given by the ancients to a chain of mountains, which commenced in Asia Minor, occupied the northern part of Cilicia, and proceeded to join, towards the north of Syria, mount Amanus; but afterwards the name has comprehended the mountains which reach from the Taurus of the ancients to the south of the Caspian sea.—Also, the name of a promontory on the eastern coast of Sicily. Ptolemy.—Also, a mountain of Scythia. It is a branch of mount Taurus that extends to the environs of the Palus Mæotides and the Caspian sea. Jornandes.—Also, a mountain of Germany, and a mountain of Æthiopia.—Also, a place of Palestine, at the entrance of the town of Jericho.—Also, a river of Greece, in the Peloponnesus.—Also, a river of Asia, in the vicinity of Pamphylia.—Also, the

name of one of the three canals by which the town of Alexandria, in Egypt, communicates with the sea.—Also, a place of Sicily, 60 stadia from the town of Syracuse.—Also, a marsh of Gallia Narbonnensis.

TAURUS, in *Geography*, was a general name given by the ancients to any thing of a gigantic nature, and hence it has been applied to a celebrated range of mountains, which is said to extend from the Grecian Archipelago to the extremities of Asia. By Strabo it is thought to originate in Caria and Pamphylia; and by some modern geographers, on the coast of Cilicia, not far from Scanderoon. However this be, it intersects Asia Minor from E. to W., and advancing in a N.E. direction, intercepts the course of the Euphrates, and spreads itself over the kingdom of Armenia, where it unites with mount Caucasus. It then detaches a variety of branches into Persia, of which the most conspicuous is that named Mont Zagros by the ancients. This long and lofty range formerly divided Media from Assyria, and now forms the boundary of the Persian and Turkish empires. It runs parallel with the river Tigris and Persian gulf, and almost disappearing in the vicinity of Gombroon, seems once more to rise in the northern districts of Kerman, and following an easterly course through the centre of Meckraun and Balouchistan, is entirely lost in the deserts of Sinde.

TAURUS, in some *Ancient Customs*, signifies a husband.

Leg. H. I. cap. 7. "Videtur autem matris ejus, cujus-cunque taurus alluserit."

TAURUS, in *Entomology*, a species of *Scarabeus*.—Also, a species of *Cicada*, found in Coromandel.—Also, a species of *Cimex*.

TAURUS, in *Ornithology*, a name given by the ancients to the bittern or butter-bump, from its imitating the roaring of a bull in its noise.

TAURUS, in *Zoology*. See **Bos** and **BULL**.

TAURUS Æthiopicus, the *Æthiopian Bull*, an animal described in a very remarkable manner by Pliny; but so contrary to the course of nature, that we may very justly rank it among the other extraordinary animals, such as the mantichora and the vermis cæruleus, of sixty or seventy feet in length.

TAUSA, in *Geography*, a town of Saxony, in the circle of Neustadt; 2 miles N. of Ziegenbruck.

TAUSCHELIN, a town of Bohemia, in the circle of Schlan; 10 miles W.N.W. of Schlan.

TAUSCHIN, a town of Bohemia, in the circle of Kaurzim; 7 miles S.E. of Kosteletz.

TAUSEN, JOHN, in *Biography*, called the "Danish Luther," because he was one of the first promoters of the reformation in Denmark, was born of parents who were peasants in the isle of Fyen, in the year 1499. Having finished his course of education, he became a monk in the convent of the order of St. John of Jerusalem, at Antoorzkow, and here he ingratiated himself so much with the prior, that he obtained a pension for travelling into foreign countries, on condition that he should avoid Wittenberg, which was at that time the focus of heresy. In his progress he visited Louvain and Cologne, where he had an opportunity of perusing some of the works of Luther, with which he was so captivated, that he could not resist the inclination of proceeding to Wittenberg, notwithstanding the prior's interdiction. In this place he pursued his studies under the instruction of Melancthon with such success, that he was appointed to give public lectures on theology in the university of Copenhagen. In his convent, to which he was soon recalled, he frequently preached; and at length, viz. in 1524, publicly avowed himself a disciple of Luther. The consequence

quence was his expulsion from the convent at Antoorfchow, and his retirement to another at Wiborg. As he here propagated his doctrine, he was imprisoned by the prior; but by this act of severity he was emboldened to proceed, and preached to the populace from a window. Being liberated in 1526, he was in the same year appointed chaplain to the king, and permitted to preach openly at Wiborg. He soon acquired a number of followers, who went to church armed, in order to protect him from the violence of the Papists. In 1529 he was invited to officiate in the church of St. Nicholas, at Copenhagen; and in the following year he attended, as director, at a conference which took place in that city between the Lutherans and the Roman Catholics. On the death of Frederic I. he was banished from Zealand, but being after a few days invited to return, he was appointed clergyman and lecturer in theology at Roschkind. In 1542 he was advanced to the episcopal chair of Ribe, and died in the year 1561. *Tausen*, besides an improved Danish translation of the Psalms, printed in 1544, and at Copenhagen in 1557, was the author of several works, consisting of Danish hymns, and treatises on the doctrine of Luther. A full account of his meritorious services may be found in Professor Munter's History of the Reformation in Denmark, &c. Gen. Biog.

TAUSS, or **DOMAZLITZ**, in *Geography*, a town of Bohemia, in the circle of Pilsen; 26 miles S.S.W. of Pilsen. N. lat. $49^{\circ} 25'$. E. long. $12^{\circ} 52'$.

TAUSTE, a town of Spain, in Aragon; 25 miles N.W. of Saragossa.

TAUTENBURG, a town and citadel of Saxony, in Thuringia; 3 miles S. of Camburg.

TAUTICA, in *Ancient Geography*, a town of Asia, in Media.

TAUTOLOGICAL ECHOES, are such echoes as repeat the same sound or syllable many times. See **ECHO**.

TAUTOLOGY, in *Grammar*, a needless repetition of the same sense in different words; or, a representation of any thing as the cause, condition, or consequence of itself. Of the first kind is that of Virgil:

“———*Si fata virum servant, si vespicitur aura
Ætherea, neque adhuc crudelibus occubat umbris.*”

Such also is this of Addison:

“The dawn is overcast:—the morning lours;
And heavily in clouds brings on the day.” Cato.

Here the same thought is repeated thrice in different words.

It is also considered as of the nature of tautology, to lengthen a sentence by coupling words altogether or nearly synonymous, whether they be substantives or adjectives, verbs or adverbs. This is a very common fault, and to be found even in our best writers. It should ever be remembered, as an invariable maxim, that words which add nothing to the sense or to the clearness, must diminish the force of the expression. There are two occasions, however, on which synonymous words may be properly used. One is, when an obscurer term, which we cannot avoid employing, on account of some connection with what either precedes or follows, needs to be explained by one that is clearer: the other is, when the language of the passions is exhibited. Passion dwells on its object; the impassioned speaker always attempts to rise in expression; but when that is impracticable, he recurs to repetition and synonymy, and thus produces in a degree the same effect. An adjective and its substantive will sometimes include a tautology. Moreover, in some single words, there is so much the appearance of tauto-

logy, that they ought, in prose at least, to be avoided; such are worse for worse, lesser for less, chiefest for chief, extreme for extreme; Most Highest, as in the liturgy, for Most High. Campbell's *Philosophy of Rhetoric*, vol. ii.

TAUVES, in *Geography*, a town of France, in the department of the Puy de Dôme; 15 miles W. of Besse.

TAUVO, a small island on the E. side of the gulf of Bothnia. N. lat. $64^{\circ} 50'$. E. long. $24^{\circ} 31'$.

TAVY, a river of England, which rises in Devonshire, passes by Tavistock, &c. and joins the Tamar, two miles below Saltafh.

TAUZIM. See **TEUSING**.

TAW, a river of England, which rises about three miles S.E. from Oakhampton, and runs into the Bristol channel below Appledore, forming a large bay at its mouth, called Barnstaple bay.

TAW, a town of Prussia; 23 miles W.S.W. of Tilsit.

TAWALLY, one of the Molucca islands, 25 miles long from north to south, and from 5 to 9 broad. S. lat. $0^{\circ} 21'$. E. long. $127^{\circ} 14'$.

TAWANDEE CREEK, a river of Pennsylvania, which runs into the E. branch of the Susquehanna, N. lat. $41^{\circ} 45'$. W. long. $76^{\circ} 30'$.

TAWARRAN, a town on the N.W. coast of the island of Borneo. N. lat. $6^{\circ} 9'$. E. long. $116^{\circ} 15'$.

TAWAS, Indians in the Ohio, on the river Miami of the Lake.

TAWEE-TAWEE, an island in the Sooloo Archipelago, 30 miles long, and from 3 to 10 broad. N. lat. $5^{\circ} 15'$. E. long. 120° .

TAWING, **SKINNING**, the art or manner of preparing or dressing skins in white, to fit them for use in divers manufactures, particularly for gloves, &c.

All kinds of skins may be tawed; but it is chiefly those of sheep, lambs, kids, and goats, that are used to be dressed this way, as being those fittest for gloves.

Method of tawing or dressing skins in white.—The wool or hair being well got off the skins by means of lime, &c. (as described under the article **SHAMMY**,) they are laid in a large vat of wood or stone, set in the ground, full of water, in which quick-lime has been slaked; in this they continue a month or six weeks, as the weather is more or less hot, or as the skins are required to be more or less soft and pliant.

While in the vat, the water and lime are changed twice, and they are taken out and put in again every day. When taken out for the last time, they are laid all night to soak in a running water, to get out the greatest part of the lime; and in the morning they are laid six together on the wooden leg, to get off the flesh by scraping them stoutly, one after another, on the flesh-side with a cutting two-handed instrument, called a knife; and while this is in hand, they cut off the legs, and other superfluous parts about the extremes.

This done, they are laid in a vat or pit with a little water; where, being well filled with wooden pestles for a quarter of an hour, the vat is filled up with water, and the skins are rinsed in it. They are next thrown on a clean pavement to drain; which done, they are cast into a fresh pit of water, where being well rinsed they are taken out, and laid on the wooden leg six at once, with the hair-side outermost, over which they rub a kind of whetstone very briskly, to soften and fit them to receive four or five more preparations given them on the leg, both on the flesh-side and the hair-side, with the knife, after the manner above-mentioned.

They are then put into a pit with water and wheat-bran, and stirred about in it with wooden poles, till the bran is perceived

perceived to stick to them, and then are left. After this, as they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom, and, at the same time, fire is set to the liquor, which takes as easily as if it were brandy, but goes out the moment the skins are all covered.

This operation is repeated as often as the skins rise above water; and when they rise no more, they are taken out, laid on the wooden leg, the flesh-side outermost, and the knife is passed over it to scrape off the bran. The bran thus cleared, the skins are laid in a large basket, where they are loaded with huge stones to promote their draining; and when sufficiently drained their feeding is given them, which is performed after the following manner: For 100 large sheep-skins, and for smaller in proportion, they take eight pounds of alum and three of sea-salt, melt the whole with water in a vessel over the fire, pouring the solution out, while yet lukewarm, into a kind of trough, in which are 20 pounds of the finest wheat-flour, with eight dozen yolks of eggs; of all this together is formed a kind of paste, a little thicker than children's pap, which, when done, is put into another vessel, to be used in manner following.

A quantity of hot water being poured into the trough in which the paste was prepared, two spoonfuls of the paste are mixed with it; in order to which they use a wooden spoon, which contains just what is required for a dozen skins; and when the whole is well diluted, two dozen of the skins are plunged into it, care being taken by the way, that the water be not too hot, which would spoil both the paste and hurt the skins. Having staid some time in the trough, they are taken out one after another with the hand, and stretched out; this is repeated twice; when they have all had their paste, they are put into tubs, where they are filled afresh with wooden pestles:

Then they are put into a vat, where they remain five or six days or more, and are at last taken out in fair weather, and hung out to dry on cords or racks; the quicker they dry the better, for if they be too long in drying, the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are put up into bundles, and just dipt in fair water; from which being taken out and drained, they are thrown into an empty tub, and, after some time, are taken out, and well trampled under foot.

They are then drawn over a flat iron instrument, the top of which is round, like a battledore, and the bottom fixed into a wooden block, to stretch and open them: when opened, they are hung in the air upon cords to dry; and when dry they are opened a second time, repassing them over the same instrument.

Lastly, they are laid on a table, pulled out and laid smooth, and are thus in a condition for sale and use.

After the same manner are dressed horses', cows', calves' skins, &c. for the saddlers, harness-makers, &c., as also dogs', wolves', bears' skins, &c. excepting that in these the use of paste is omitted, salt and alum-water being sufficient. See TANNING.

By stat. 9 Ann. c. 11. and 10 Ann. c. 26. the following duties are imposed on hides or skins tawed or dressed in Great Britain. For horse-hides dressed in alum and salt, or meal, or otherwise tawed, 1*s.* 6*d.* a hide; hides of steers, cows, and all other (except horse-hides) dressed in alum and salt or meal, or otherwise tawed, 3*s.* a hide; calve-skins and kips, dressed in alum and salt or meal, or otherwise tawed, 1½*d.* a pound; skins so dressed or tawed with the hair on, 3*s.* a dozen, and without hair, 1*s.* a dozen; dog-skins so

dressed or tawed, 1*s.* a dozen; buck and doe-skins (except what paid the duty on importation) dressed in alum and salt or meal, or otherwise tawed, 6*d.* a pound; kid-skins so dressed or tawed, except as before, 1*s.* a dozen; goat-skins so dressed or tawed, 2*s.* a dozen; beaver-skins so tawed, 2*s.* a dozen; sheep-skins and lamb-skins so dressed or tawed, 1½*d.* a pound; and all other tawed skins, not before charged, 30*s.* for every 100*l.* value. All these duties are to be paid by the tawers or makers.

For hides and skins dressed in oil, 6*d.* a pound; deer, goat, and beaver-skins dressed in oil, 6*d.* a pound; calve-skins dressed in oil, 8*d.* a pound; sheep and lamb-skins dressed in oil, 3*d.* a pound; all skins dressed in oil, not before charged, 15*s.* in the 100*l.* according to the real value; all which are to be paid by the oil leather-dressers.

For other regulations, see LEATHER and TANNER.

TAX, formed from τὰξίς, *order*, denotes a certain aid, subsidy, or supply, granted by the commons of Great Britain in parliament assembled, constituting the king's extraordinary revenue; and paid yearly towards the expences of the government. See MONEY-BILLS, PARLIAMENT, and SUPPLY.

Anciently, the tax seems to have been imposed by the king at his pleasure; but Edward I. bound himself, and his successors, from that time forward, not to levy it, but by consent of the realm.

To this purpose the celebrated Mr. Locke, in his "Essay on Government," (ch. xi. § 140.) lays down the following proposition as fundamental. "Tis true, government cannot be supported without great charge; and 'tis fit every one who enjoys his share of protection, should pay out of his estate his proportion for the maintenance of it. But still it must be with his own consent, *i. e.* the consent of the majority, giving it either by themselves, or their representatives chosen by them: for if any one shall claim a power to lay and levy taxes on the people by his own authority, and without such consent of the people, he thereby invades the fundamental law of property, and subverts the end of government. For what property have I in that, which another may by right take when he pleases to himself?"

Dr. Adam Smith, the ingenious author of "An Enquiry into the Nature and Causes of the Wealth of Nations," to whose work we have had occasion to refer, lays down (vol. ii. p. 2.) the four following maxims with regard to taxes in general. "1. The subjects of every state ought to contribute towards the support of the government, as nearly as possible, in proportion to their respective abilities, that is, in proportion to the revenue which they respectively enjoy under the protection of the state. 2. The tax, which each individual is bound to pay, ought to be certain, and not arbitrary. The time of payment, the manner of payment, the quantity to be paid, ought all to be clear and plain to the contributor, and to every other person. When it is otherwise, every person subject to the tax is put more or less in the power of the tax-gatherer, who can either aggravate the tax upon any obnoxious contributor, or extort, by the licence of such aggravation, some present or perquisite to himself. 3. Every tax ought to be levied at the time, or in the manner, in which it is most likely to be convenient for the contributor to pay it. 4. Every tax ought to be so contrived, as both to take out and to keep out of the pockets

TAX.

pockets of the people as little as possible, over and above what it brings into the public treasury of the state." This maxim may be counteracted by requiring for the levying of the tax a great number of officers, whose salaries may consume the greater part of the produce of the tax, and whose perquisites may impose another tax upon the people;—by obstructing their industry, and discouraging them from applying to certain branches of business, which might give maintenance and employment to great multitudes;—by the forfeitures and other penalties which those unfortunate individuals incur, who attempt unsuccessfully to evade the tax, which may ruin them, and thus put an end to the benefit the community might have received from the employment of their capitals; the penalties of smuggling being so ordered as to rise in proportion to the temptation; and by subjecting the people to the frequent visits and the odious examination of the tax-gatherers, which occasion much trouble, vexation, and oppression.

As the private revenue of individuals arises ultimately from the three different sources of rent, profit, and wages, every tax must finally be paid from one or other of these three different sorts of revenue, or from all of them indifferently. The first kind of taxes comprehends those upon the rent of land. (See LAND-TAX.) Taxes upon the produce of the land are in reality taxes upon the rent. (See TITHES.) Taxes upon the rent of houses include that which may be called the Building rent, and that which is commonly called the Ground rent; and so far as these fall upon the inhabitants, they must be drawn from the same source as the rent itself, and must be paid from their revenue, whether derived from the wages of labour, the profits of stock, or the rent of land; and it is in every respect of the same nature as a tax upon any other sort of consumable commodities. Houses not inhabited ought to pay no tax; houses inhabited by the proprietor ought to be rated, not according to the expence which they might have cost in building, but according to the rent which an equitable arbitration might judge them likely to bring, if leased to a tenant. Ground rents are still a more proper subject of taxation than the rent of houses, or even the rent of land. The principal objection to all taxes upon houses and windows is their inequality, and therefore they are directly contrary to the first of Dr. Smith's maxims above stated. Their natural tendency is to lower rents.

Taxes upon profit, or upon the revenue arising from stock, comprehend the tax upon stock, such as is imposed by the land-tax in England, by which it was intended that the stock should be taxed in the same proportion as the land, and taxes upon the profit of particular employments. Taxes upon the wages of labour must finally fall upon the consumer. Besides the taxes already enumerated, there are others, such as capitation taxes, and taxes upon consumable commodities, which must be paid indifferently from whatever revenue the contributors may possess; from the rent of their land, from the profits of their stock, or from the wages of their labour. The impossibility of taxing the people, in proportion to their revenue, by any capitation, seems to have given occasion to the invention of taxes upon consumable commodities; and these are either necessaries or luxuries. A tax upon the necessaries of life operates exactly in the same manner as a direct tax upon the wages of labour, and will fall, if the labourer be employed by a manufacturer, on the consumer; or if he be employed by a farmer, it will fall upon the rent of the landlord. But it is otherwise with respect to taxes upon luxuries. The rise in the price of the taxed commodities, will not necessarily occasion any rise in the wages of labour. Any rise in the average

price of necessaries, unless it is compensated by a proportionable rise in the wages of labour, must necessarily diminish more or less the ability of the poor to bring up numerous families, and consequently to supply the demand for useful labour; whatever may be the state of that demand, whether increasing, stationary, or declining; or such as requires an increasing, stationary, or declining population.

Taxes upon luxuries have no tendency to raise the price of any other commodities except that of the commodities taxed. Taxes upon necessaries, by raising the wages of labour, necessarily tend to raise the price of all manufactures, and consequently to diminish the extent of their sale and consumption. Taxes upon luxuries are finally paid by the consumers of the commodities taxed, without any retribution. They fall indifferently upon every species of revenue, the wages of labour, the profits of stock, and the rent of land. Taxes upon necessaries, so far as they affect the labouring poor, are finally paid, partly by landlords in the diminished rent of their lands, and partly by rich consumers, whether landlords or others, in the advanced price of manufactured goods; and always with a considerable over-charge.

In Great Britain, the principal taxes upon the necessaries of life are those upon salt, leather, soap, and candles. Heavy taxes upon these commodities must somewhat increase the expence of the sober and industrious poor, and must, consequently, more or less raise the wages of their labour. Such taxes, notwithstanding their immediate effect, afford a considerable revenue to government, and accordingly they are continued and multiplied.

Consumable commodities, whether necessaries or luxuries, may be taxed in two different ways. The consumer may either pay an annual sum on account of his using or consuming goods of a certain kind; or the goods may be taxed while they remain in the hands of the dealer, and before they are delivered to the consumer. The consumable goods which last a considerable time before they are consumed altogether, are most properly taxed in the one way. Those of which the consumption is either immediate or more speedy, in the other.

Of the latter kind is the greater part of the duties of excise and customs. Those of excise are imposed chiefly upon goods of home produce destined for home consumption; and they are imposed only upon a few sorts of goods of the most general use. The duties of customs are much more ancient than those of excise. (See CUSTOMS and EXCISE.) It is observed that high taxes, sometimes by diminishing the consumption of the taxed commodities, and sometimes by encouraging smuggling, frequently afford a smaller revenue to government than what might be drawn from more moderate taxes.

When the diminution of revenue is the effect of the diminution of consumption, there can be but one remedy, and that is the lowering of the tax.

When the diminution of the revenue is the effect of the encouragement given to smuggling, it may perhaps be remedied in two ways; either by diminishing the temptation to smuggle, or by increasing the difficulty of smuggling. The temptation to smuggle can be diminished only by the lowering of the tax; and the difficulty of smuggling can be increased only by establishing that system of administration which is most proper for preventing it.

The duties upon foreign luxuries imported for home consumption, though they sometimes fall upon the poor, fall principally upon people of middling or more than middling fortune. Such are, for example, the duties upon foreign wines, upon coffee, chocolate, tea, sugar, &c.

TAX.

The duties upon the cheaper luxuries of home produce destined for home consumption, fall pretty equally upon people of all ranks in proportion to their respective expence. The poor pay the duties upon malt, hops, beer, and ale, upon their own consumption: the rich, upon both their own consumption and that of their servants.

The whole consumption of the inferior ranks of people, or of those below the middling rank, it must be observed, is in every country much greater, not only in quantity, but in value, than that of the middling and of those above the middling rank. The whole expence of the inferior is much greater than that of the superior ranks. Although the expence of people of inferior ranks, taking them individually, is very small, yet the whole mass of it, taking them collectively, amounts always to by much the largest portion of the whole expence of the society; what remains, of the annual produce of the land and labour of the country for the consumption of the superior ranks, being always much less, not only in quantity but in value. The taxes upon expence, therefore, which fall chiefly upon that of the superior ranks of people, upon the smaller portion of the annual produce, are likely to be much less productive than either those which fall indifferently upon the expence of all ranks, or even those which fall chiefly upon that of the inferior ranks; than either those which fall indifferently upon the whole annual produce, or those which fall chiefly upon the larger portion of it.

The best taxes, says Mr. Hume, (vol. i. Ess. 8.) are such as are levied upon consumptions, especially those of luxury; because such taxes are least felt by the people. They seem, in some measure, voluntary: since a man may chuse how far he will use the commodity which is taxed. They are paid gradually and insensibly; they naturally produce sobriety and frugality, if judiciously imposed; and being compounded with the natural price of the commodity, they are scarcely perceived by the consumers. Their only disadvantage is, that they are expensive in levying. Taxes upon possessions are levied without expence; but they have every other disadvantage. Most states, however, are obliged to have recourse to them, in order to supply the deficiencies of the other. When a tax is laid upon commodities which are consumed by the common people, the necessary consequence may seem to be, either that the poor must retrench something from their way of living, or raise their wages, so as to make the burden of the tax fall upon the rich; but there is a third consequence, which often follows upon taxes, namely, that the poor increase their industry, perform more work, and live as well as before, without demanding more for their labour. Where taxes are moderate, are laid on gradually, and do not affect the necessaries of life, this consequence naturally follows; and it is certain, that such difficulties often serve to excite the industry of a people, and render them more opulent and laborious than others, who enjoy the greatest advantages. The most pernicious of all taxes are the arbitrary: they are commonly converted, by their management, into punishments on industry; and, also, by their unavoidable inequality, are more grievous than the real burden which they impose. Poll-taxes are commonly arbitrary. A duty upon commodities checks itself; and a prince will find, that an increase of the impost is no increase of his revenue.

After all the proper subjects of taxation have been exhausted, if the exigencies of the state still continue to require new taxes, they must be imposed upon improper ones. It has been well observed, "that oppressive taxation is a monster, which, after devouring every other thing, devours itself at last."

The taxes which are raised on the British subject are either annual or perpetual. The usual annual taxes are those upon land and malt.

The first of these is the land-tax, for an account of which see *LAND-TAX*.

See also *HIDAGE, SCUTAGE, TALLIAGE, TENTH, FIFTEENTH, and SUBSIDY*.

The other annual tax is the malt-tax, which is a sum raised every year by parliament ever since 1697. See *MALT*.

The perpetual taxes are the customs, which are a tax immediately paid by the merchant, although ultimately by the consumer (see *CUSTOMS*); the excise-duty, which is an inland imposition, paid sometimes upon the consumption of the commodity, or frequently upon the retail sale, which is the last stage before the consumption (see *EXCISE*); the duty upon *salt*: that for the carriage of letters or *post*; the *stamp-duties*; the duty upon houses and *windows*; the duty arising from licences to hackney-coaches and chairs in London, and the parts adjacent; and the duty upon offices and pensions. See *LAND-TAX, &c. &c.*

The assessed taxes comprehend those on windows, houses, servants, carriages, horses and mules, dogs, horse-dealers, hair-powder, armorial bearings, and game licences. For those on windows, see the following schedule.

Schedule (A.) 48 G. III. c. 55.

Number of windows according to which the duties shall be charged.	Duties. £ s. d.
Not more than 6 windows or lights (except in such houses which shall be worth the rent of 5 <i>l.</i> by the year, and shall be charged to the duty mentioned in Schedule (B.), according to the rent thereof)	0 6 6
Not more than 6 windows or lights, if of the value before-mentioned, and charged to the said duty accordingly	0 8 0

7 - do.	- - - - -	4	16	0
8 - do.	- - - - -	5	3	0
9 - do.	- - - - -	5	12	0
10 - do.	- - - - -	6	3	0
11 - do. and upwards	- - - - -	7	1	0

For every such servant retained or employed by any male persons, never having been married, over and above the before-mentioned duties, the further sum of - - - - - 1 14 0

Schedule (C.) N° 2. Duties payable annually for male servants retained or employed in the several capacities herein mentioned.

For every gardener or person employed to work in any garden under any person chargeable to the duties mentioned in Schedule (C.), N° 1; and for every gardener employed in any garden wherein the constant labour of one person shall not be necessary, the sum of - 0 6 0

To be paid by each person in whose garden such person shall be employed.

Exemptions from the Duties as set forth in Schedule (C.) N° 1. and 2.

Any person employed by the day or week to work as a day labourer, at the usual rate of wages for day labourers in agriculture, in any garden belonging to a dwelling-house, being a farm-house, and exempted as such from the duties mentioned in Schedule (B.), or in any garden belonging to a dwelling-house not chargeable to the duties mentioned in the said schedule, such garden not requiring the constant labour of one such labourer.

Schedule (C.) N° 3. Duties payable annually for every male person or servant retained or employed in the several capacities herein mentioned.

For every male person employed by any merchant or trader as a traveller or rider, the duties following; viz.

Where one such traveller or rider and no more shall be so employed, the sum of - - - 2 8 0

And where more than one such traveller or rider shall be so employed, for each the sum of - 3 10 0

For every male person employed by any person in trade, or exercising any profession whatever, as a clerk or book-keeper, or office-keeper, except apprentices, where no premium, or a premium less in value than the sum of 20l. has been paid or contracted for with such apprentice, the duties following; viz.

Where one such clerk, book-keeper, or office-keeper, and no more shall be so employed, the sum of - - - - - 1 4 0

And where more than one such clerk, book-keeper, or office-keeper shall be so employed, for each the sum of - - - - - 2 8 0

For every male person employed by any person in trade as a shopman, for the purpose of exposing to sale or selling goods, wares, or merchandise, in such shop or warehouse, whether by wholesale or retail; and every male person employed as a warehouseman, porter, or cellarman, in such shop or warehouse, except apprentices as aforefaid, the sum of - - - 1 4 0

The said duties to be paid by the employer or employers of such persons, and to extend to every body politic or corporate, whether aggregate or sole, and to every society, fraternity, or partnership, although not corporate; and to every manufacture or concern (except husbandry) whereby the employer shall seek a profit.

TAX.

For every male servant employed as a waiter (except occasional waiters, over and above the ordinary number usually kept) in any taverns, coffee-houses, inns, ale-houses, or other licensed houses, or in eating or victualling houses, or in hotels or lodging-houses, being eating or victualling houses, the sum of -

£ s. d. Schedule (D.) N^o 1. Duties payable on all carriages of any of the descriptions mentioned herein.

		Number of Carriages.	Amount of Duty for each Carriage.	
			£ s. d.	
2	5	0	For 1 such carriage, the annual sum of -	11 5 0
			2 - do. - - - - -	12 7 0

			1	4

For every male servant retained by any stable-keeper to take care of any horse, mare, or gelding, of any other person or persons, kept for the purpose of racing or running for any plate, prize, sum of money, or other thing, or any horse, mare, or gelding, in training for any of the said purposes, whereby such stable-keeper shall gain a livelihood or profit, the sum of - - - - -

For every male servant *bonâ fide* retained for the purposes of husbandry, manufacture, or trade, by which the master or mistress shall gain a livelihood or profit, and at any time employed in any domestic employment in any of the capacities in Schedule (C.), N^o 1, and not chargeable to the duties in the said schedule, the sum of - - - - -

Schedule (D.) N^o 2.

For carriages with less than four wheels:

For every such carriage (except taxed carts, constructed, kept, and used, under the regulations of this act) drawn by one horse, mare, or gelding, and no more - - - - -

And for every such carriage, drawn by two or more horses, mares, or geldings - - - - -

And for every additional body of the description herein-after mentioned, successively used on the same carriage or number of wheels, the further sum of - - - - -

0	6	0	5 18 0
			8 5 0
			2 16 0

For every male servant *bonâ fide* retained for the purposes of husbandry, or any manufacture or trade, by which the master or mistress shall gain a livelihood or profit, and at any time employed in the capacity of a groom, stable-boy, or helper in the stables, where the master or mistress shall be chargeable for one horse, and no more, to the duty on horses kept for the purposes of riding, or drawing a taxed cart, or to the duty on such taxed cart, and not on any other carriage chargeable with duty by this act, the sum of - - - - -

The said last-mentioned duties to be paid by the employer, or master or mistress of such persons or servants.

Schedule (C.) N^o 4. Duties payable on servants let to hire.

For every coachman, groom, postilion, or helper, kept for the purpose of being let to hire for any period of time less than one year, and in such manner that the stamp-office duty payable by law on horses let to hire shall not be payable on every such letting by any post-master, inn-keeper, or other person, duly licensed to let post-horses by the commissioners for managing the duties on stamped vellum, parchment, and paper, or by any coach-maker or maker of such carriages, or other person, the annual sum of - - - - -

Schedule (D.) N^o 3.

For carriages hired for any period of time less than one year, or kept to be let to hire, or to carry passengers:

For every such carriage kept for the purpose of being let to hire, with horses to be used therewith, for any period of time not exceeding twenty-eight days, so that the stamp-office duty, payable by law on horses let to hire shall be duly paid and satisfied on every such letting by any post-master, inn-keeper, or other person duly licensed to let post-horses, by the commissioners for managing the duties on stamped vellum, parchment, and paper, and whereon the name or names and place of abode of the person or persons so licensed shall be marked or painted, according to the directions of the act in that case made and provided; if such carriage shall have four wheels, the sum of - - - - -

And if such carriage shall have less than four wheels, the respective sums mentioned in Schedule (D.) N^o 2, according to the number of horses used therewith, as therein mentioned.

And for every coach, diligence, caravan, or chaise with four wheels or more, or other carriage with four wheels or more, by whatever name the same shall be called or known, which shall be kept and employed as a public stage-coach or carriage for the purpose of conveying passengers for hire to and from different places, and which shall be duly entered as such with the said commissioners, of stamp duties, the like sum of - - - - -

The said duty to be paid by the person or persons letting the same to hire.

These several duties are subject to certain exemptions. The provisions of 43 Geo. III. c. 161. relating to the assessments of servants, are as follow. Persons liable to these duties are to return lists of their servants, and are chargeable accordingly from the year commencing from the days stated in their returns; and they are subject to the powers of surcharge. Persons beginning or ceasing to keep servants are to give notice in writing to the assessor of the district in which they reside.

			All

TAX.

All which last-mentioned duties shall respectively be paid by the person or persons keeping the same, for the purposes aforesaid. £ s. d.

For every carriage kept for the purpose of being let to hire for any period of time less than one year, and in such manner that the said stamp-office duty shall not by law be payable on such letting by any person so licensed as aforesaid, or by any coach-maker or maker of such carriages, or other person, if such carriage shall have four wheels, the annual sum of - - - - - 11 5 0

The said last-mentioned duty to be paid by the person or persons keeping the same for the purposes aforesaid.

Provided, if a due return thereof shall not be made by the hirer or hirers according to the directions of the acts herein mentioned, the progressive duty, as set forth in Schedule (D.) N^o 1, shall be chargeable in respect of every such carriage on the person or persons hiring the same, and making such default as aforesaid, subject to the provisions contained in the said acts concerning the same.

And if such carriage shall have less than four wheels, the respective sums mentioned in Schedule (D.) N^o 2, according to the number of horses to be used therewith, to be paid by the person or persons keeping the same for the purpose aforesaid, subject to the provisions herein-after contained concerning the same. See COACH and Taxed CART.

By 50 Geo. III. c. 104. certain new duties are imposed.

A Schedule of the Duties payable on Carriages called Taxed Carts.

N^o I.

For every carriage called a taxed cart, built and constructed according to the regulations of the said act, in every respect the original price of which shall not have exceeded, or the value whereof shall not at any time exceed the sum of 15*l.* sterling, and which shall not at any time be used with a covered or stuffed seat, or with a covered foot-board or apron thereto fixed or not fixed, there shall be charged the annual sum of - - - - - 1 6 6

N^o II.

For every such carriage called a taxed cart, built and constructed with a spring or springs of any materials whatever, (except of iron, steel, or any other metallic substance, or any composition of iron, steel, or other metallic substance, either wholly or in part,) the original price of which carriage shall not have exceeded, or the value whereof shall not at any time exceed the sum of 20*l.* sterling, or which shall be used with a stuffed seat or cushion, or with a covered foot-board or apron thereto fixed or not fixed, there shall be charged the annual sum of - - - - - 2 10 0

A Schedule of the Duties payable on Carriages with less than Four Wheels.

N^o III.

For every carriage with less than four wheels chargeable by the said act of the forty-eighth

of his present majesty's reign with the duty of 5*l.* 18*s.* if drawn by one horse, mare, or gelding, and no more, there shall be charged the like amount of duty for every such carriage drawn by one horse, mare, gelding or mule, and no more, viz. the annual sum of - - - 5 18 0

For every such carriage chargeable by the said act with the duty of 8*l.* 5*s.* if drawn by two or more horses, mares, or geldings, there shall be charged the like amount of duty for every such carriage drawn by more than one horse, mare, gelding or mule, viz. the annual sum of 8 5 0

And for any additional body successively used on the same carriage or number of wheels chargeable by the said act with the further duty of 2*l.* 16*s.* there shall be charged the like amount of further duty, for every additional body successively used on the same carriage or number of wheels, if drawn in the manner herein mentioned, viz. the further annual sum of - 2 16 0

Schedule (E.) N^o 1. Duties payable for all horses, mares and geldings, kept and used for the purpose of riding, or of drawing any carriage chargeable with duty by Schedule (D.)

	Number thereof.	Amount of Duty for each Horse, Mare, or Gelding.
		£ s. d.
For 1 such horse, mare, or gelding	-	2 13 6
2 such horses, mares, or geldings	-	4 9 6

18 - do.	-	5 19 6
19 - do.	-	6 0 0
20 and upwards	-	6 1 0

Rules.—The said duties to be payable annually for every horse, mare, or gelding, used on any occasion for the purpose of riding, or of drawing any carriage for which any duty is payable by this act, or hired by the year, or any longer period, and to be paid by the person or persons using the same. These duties are subject to certain exemptions in favour of husbandry, under certain circumstances.

Schedule (E.) N^o 2. Duties payable on horses let to hire.

For every horse, mare, or gelding, let to hire for the purpose of riding, or of drawing any such carriage as aforesaid, for any period of time less than one year, in any manner so that the stamp-office duty payable by law on horses let to hire shall not be payable, the sum of - 2 13 6

To be charged annually on the person or persons letting the same; provided, if a due return thereof shall not be made by the hirer or hirers, according to this act, the progressive duty, as set forth in Schedule (E.) N^o 1, shall be chargeable in respect of every such horse, mare, or gelding, on the person or persons hiring the same, and making such default as aforesaid, subject to the provisions of this act.

Schedule (E.) N^o 3. Duties payable on horses kept for the purpose of racing or running for any plate, prize, or sum of money, or other thing, or kept in training for any of the said purposes.

For every horse, mare, or gelding, *bonâ fide* kept for the purpose of racing or running for any plate, prize, or sum of money, or other thing, or kept in training for any of the said purposes, whether in the stables of the proprietor or proprietors, or of any other person or persons, the sum of - - - - - £ s. d.

The said duty to be charged annually on the person or persons having the custody, charge, or management of such horses, mares, or geldings.

Schedule (F.) N^o 1. Duties payable for all horses, mares, and geldings, not charged with any duty according to the Schedule (E.) N^o 1, 2, 3, and also on mules.

For every horse, &c. not chargeable with any duty according to the Schedule (E.) N^o 1, 2, and 3, as aforesaid, and for every mule, except in the cases herein-after mentioned, where-in other duties are made payable, the sum of - - - - - £ s. d.

Schedule (F.) N^o 2. Duties payable on husbandry-horses, in the cases herein-after mentioned.

Any person occupying a farm at rack-rent, the rent of which shall be less than 20*l.* a-year, and making a livelihood solely thereby, or occupying any estate on any other tenure than as tenant at rack-rent solely, or such other estate, together with the farm at rack-rent, the value of which in the whole shall be less than equivalent to a farm at the rack-rent of 20*l.* a-year (reckoning the value of every estate occupied by the owner thereof, or on any tenure other than as tenant at rack-rent, as equivalent to double the amount of the like farm at rack-rent), and making a livelihood solely by such his own estate, or by such estate and farm jointly, or principally thereby, and likewise a profit by any trade or employment, and keeping not more than two horses, mares, geldings, or mules, *bonâ fide* for the purpose of such occupation, shall be charged for each of such two horses, mares, geldings, or mules, the sum of - - - - - £ s. d.

Any person occupying a farm at rack-rent in Wales or Scotland, the rent of which shall be less than 10*l.* sterling a-year, and making a livelihood principally thereby, or occupying any estate on any other tenure than as tenant at rack-rent, or such other estate, together

with a farm at rack-rent, the value of which in the whole shall be less than equivalent to a farm at the rack-rent of 10*l.* sterling a-year (reckoning the value of every estate occupied by the owner thereof, or on any tenure other than as tenant at rack-rent, as equivalent to double the amount of the like farm, at rack-rent), and making a livelihood principally thereby, and likewise a profit by any trade or employment, and keeping not more than two horses, mares, geldings, or mules, *bonâ fide* for the purposes of such occupation, and of such trade or employment jointly, or either of them separately, shall be charged for each of such two horses, mares, geldings, or mules, the sum of - - - - - £ s. d.

Rules for charging the duties, as set forth in Schedule (F.) N^o 1 and 2.

The said duties to be charged annually, and paid by the person or persons keeping or using such horses, mares, geldings, or mules, and to be payable for every horse, mare or gelding, and mule, which shall not be chargeable nor have been charged with any duty payable in that year, according to the preceding schedule marked (E.) by virtue of the rules or exemptions therein contained, except as herein-after is mentioned.

Exemptions from the duties in Schedule (E.) N^o 1 and 2.

Any person whatever, for any horse, mare, or gelding, not being by due admeasurement of the height of thirteen hands, of four inches to each hand, or which shall not at any time whatever have been used for any purpose of labour or otherwise. See HORSE and HORSE-Dealer.

Schedule (G.) N^o 1. Duties payable on dogs.

For every greyhound, hound, pointer, setting-dog, spaniel, lurcher, or terrier, the annual sum of - - - - - £ s. d.

For every dog, of whatever description or denomination the same may be, where any person shall keep two or more dogs, either for his or her own use, or the use of any other person or persons, the annual sum of - - - - - £ s. d.

For every dog not being a greyhound, hound, pointer, setting-dog, spaniel, lurcher, or terrier, kept by any person having one such dog, and no more, whether the same be kept for his or her own use, or the use of any other person or persons, the annual sum of - - - - - £ s. d.

The said duties to be paid by the persons respectively keeping such dogs.

Exemptions from the duties in Schedule (G.)

Case 1.—Any dog belonging to his majesty, or any of the royal family.

Case 2.—Any person who, on account of poverty, shall be discharged from the assessment made in respect of his or her dwelling-house, in pursuance of the regulations of any of the acts herein-mentioned, and having one dog, and no more, the same not being a greyhound, hound, pointer, setting-dog, spaniel, lurcher, or terrier.

Case 3.—Any person, in respect of a dog or whelp, which at the time of returning the lists of dogs as by this act is required, shall not actually be of the age of six calendar months.

TAX.

Case 4.—Any person in respect of the whole number of hounds by him or her kept in Great Britain, who shall compound for the same, in any year within thirty days after the 5th day of April in such year, in pursuance of notice given to the collector or collectors of the said duty for any parish or place, where such person shall be liable to be assessed, of his or her intention so to do, and on payment of the full sum of 3*l.* sterling to such collector or collectors, for which a receipt shall be given within the period before-mentioned.

Schedule (H.) Duties payable by horse-dealers.

Every person who shall use or exercise the trade and business of a horse-dealer within the cities of London and Westminster, and the liberties of the same respectively, the parishes of St. Mary-le-Bone and St. Pancras, in the county of Middlesex, the weekly bills of mortality, or the borough of Southwark, in the county of Surrey, the annual duty of - - -	£ s. d.
Every person who shall use or exercise the trade and business of a horse-dealer in any other part of Great Britain, the annual duty of - - -	22 10 0
Every person who shall use or exercise the trade and business of a horse-dealer in any other part of Great Britain, the annual duty of - - -	11 5 0

Schedule (I.) Duties payable by persons in respect of hair-powder used or worn by them.

By every person who shall have used or worn any hair-powder within the period limited by any of the acts herein mentioned, the annual sum of - - - - -	£ s. d.
	1 3 0

Schedule (K.) Duties payable by persons in respect of any armorial bearing or ensign, used or worn by them, by whatever name the same shall be called; viz.

By every such person chargeable with any duty made payable by this act, for any coach or other carriage, the annual sum of - - -	£ s. d.
By every such person not chargeable for any such coach or other carriage, but who shall be chargeable to any of the duties on inhabited houses, or to the duties on houses, windows, or lights, made payable by this act, the annual sum of - - - - -	2 8 0
By every such person not chargeable for any such coach or other carriage, nor being chargeable to the said duties on inhabited houses, or to the duty on houses, windows, or lights, the annual sum of - - - - -	1 4 0
By every such person not chargeable for any such coach or other carriage, nor being chargeable to the said duties on inhabited houses, or to the duty on houses, windows, or lights, the annual sum of - - - - -	0 12 0

Schedule (L.) Duties payable in respect of killing game.

Upon every person who shall use any dog, gun, net, or other engine, for the purpose of taking or killing any game whatever, or any woodcock, snipe, quail or landrail, or any conies, in any part of Great Britain:	£ s. d.
If such person shall be a servant to any person duly charged in respect of such servant to the duties granted on servants by this act, and shall use any dog, gun, net, or other engine, for any of the purposes before-mentioned, upon any manor or royalty in England, Wales, or Berwick-upon-Tweed, or upon any lands in Scotland, by virtue of any deputation or appointment, duly registered or entered as game-keeper thereto, there shall be charged the annual sum of - - - - -	1 1 0

And if such person as last aforesaid shall not be a servant, for whom the said duties on servants shall be charged, there shall be charged the annual sum of - - - - - 3 3 0

Upon every other person who shall use any dog, gun, net, or other engine for any of the purposes before-mentioned, there shall be charged the annual sum of - - - - - 3 3 0

By the 46 Geo. III. c. 84. every person having more than two children born in lawful wedlock, and *bonâ fide* maintained at the expence of such person, shall for every such child above two be allowed at the rate of 4 per cent. on the amount of all the assessments on such person by virtue of the 43 Geo. III. c. 161. 45 Geo. III. c. 13. 46 Geo. III. c. 78. in case the total amount of all the assessments shall be under 40*l.* in any one year, which allowance shall be made annually out of the duties so charged, at any time in the year of assessment, on delivery of a declaration in writing, containing the whole number of such children, and their respective names and places of residence, and which of them are of the family, or reside elsewhere.

By s. 2. this provision shall extend to children by a former marriage, either of the husband or wife.

The statute 43 Geo. III. c. 99. reciting that it is expedient that certain of the provisions contained in any acts relating to the duties on windows or lights, on inhabited houses, servants, carriages, horses, mules, and dogs, and other duties lately transferred to the commissioners for the affairs of taxes, should be consolidated and amended: enacts that all the said duties under the management of such commissioners (except the land-tax) shall, from and after April 5, 1804, be assessed, raised, levied, and paid under the regulations thereof.

And as new duties may hereafter be placed under their management, to be assessed in like manner, it is declared that this act shall, with respect to such duties, take effect after the time fixed by the act or acts granting them for the commencement of the same. See the provisions of this act detailed in Burn's Justice, *ubi supra*.

The property-tax being now extinct, we are happily relieved from giving any account of it.

For the qualifications and powers of commissioners, the appointment of assessors and collectors, the mode of making assessments, surcharges, appeals, &c. &c. we refer to Burn's Justice, art. *Taxes*.

For the duty on post-horses, &c. see *Post-Horse*.

The revenue arising from the several taxes, which is annually paid to the creditors of the public, or carried to the sinking fund, is first deposited in the royal exchequer, and thence issued out to the respective offices of payment: for the manner in which it is applied, see *FUND* and *NATIONAL Debt*. See also *REVENUE*.

The people of France were strangers to *tailles* or taxes till the time of St. Louis, when they were first imposed in form of subsidies necessary for the support of the war in the Holy Land. See *CROISADE*.

They were then extraordinary levies, and were raised by capitation; but they were afterwards made perpetual under Charles VII. and Philip the Fair, who, to raise money without disturbing the people, called the people, as a third estate, into the general councils of the realm.

Tax also denotes the tribute which tenants were occasionally to pay their lord.

Most lords had a right of taxing on four occasions: viz. when the lord was taken prisoner in a just war; when he made

made his eldest son a knight; when he married his eldest daughter to a gentleman; and when he made the voyage of the Holy Land.

Naude shews the extravagant rise of this kind of taxes: those, he observes, which under Charles VI. only amounted to the sum of 40,000 livres, were increased under Charles VII. to the sum of 1,800,000; under Louis XI. to 4,740,000; under Charles VIII. to 6,000,000; and under Louis XII. to 7,640,000 livres.

Taxes were distinguished into *free*, which were those due, in the four cases, by freemen, or those who held free lands; and *servile* and *base*, which were those due from persons of base condition.

They were also distinguished into *real* and *personal*. The personal were imposed on the head of the servant or man in mainmort, and so followed him wherever he went.

TAXA, in *Geography*, one of the small Western islands, near the south-east coast of Ilay. N. lat. 55° 43'. W. long. 6° 3'.

TAXAMALCA, a town of Mexico; 60 miles S. of Mexico.

TAXAMARCA, a town of Mexico, in the province of Mechoacan; 40 miles E. of Mechoacan.

TAXANTHEMA, in *Botany*, so named by Necker, from *ταξις*, a row, and *ανθημα*, inflorescence, because some of the plants on which this supposed genus is founded differ from other species of *Statice*, in having their flowers disposed in a regular series, or row, and not in a round head; witness *S. Limonium* and its allies. These species indeed constitute Tournefort's genus of *Limonium*, but he associates with them others with dispersed flowers. (See *STATICE* and *LIMONIUM*.) Mr. Brown, Prodr. Nov. Holl. v. 1. 426, adopts Necker's genus and name, citing Tournefort's *Limonium* as a synonym. The latter name was probably judged too near *Limonia* to be retained. We presume to think the genus of *Statice* is in itself so natural, and so well distinguished from every other, that if a practical example were desired, to warn us against founding generic distinctions upon inflorescence alone, no better could be selected. See *CYME* and *GENUS*.

TAXERS, two officers yearly chosen in Cambridge, to see the true gauge of all weights and measures observed.

The name took beginning from taxing and rating the rents of houses, which was anciently the duty of their office.

TAX-GUTIUM, in *Ancient Geography*, a town of Rhatia, towards the source of the Rhine, near Brigantium. Ptol.

TAXIANA, an island situated in the Persian gulf, on the coast of Susiana, west of the isle of Tabiana. Ptol.

TAXILA, a large town of India, on this side of the Ganges. Ptol. and Strabo.

TAXIMIRA, a town of Phœnicia. Strabo.

TAXIPA, in *Geography*, a town of Mexico, in the province of Guasteca; 30 miles N.N.W. of Panuco.

TAXIS, *ταξις*, in the *Ancient Architecture*, signifies the same with ordonnance in the new, and is described by Vitruvius to be that which gives every part of a building its just dimensions with regard to its use.

TAXIS, from *τασσα*, to put in order, in *Surgery*, the operation of reducing a hernia with the hand. See a particular account of it in the article *HERNIA*.

TAXITLAN, in *Geography*, a town of Mexico, in the province of Guasteca; 38 miles S. of St. Yago de los Valles.

TAXUS, in *Botany*, the ancient Latin name of the Yew-tree, used by Pliny. The word is supposed by some to be derived from *ταξος*, a bow, arrow, or dart, because

missile weapons were poisoned with its berries. We are confident that this precise explanation is erroneous, because, whatever may be the noxious qualities of any other part of the plant, the berries are simply mucilaginous and saccharine, eatable with impunity, as we have often experienced. The ancient use of this wood for bows, perhaps also for arrows or darts, might more truly account for the above etymology, did not Dioscorides expressly tell us *ταξος*; was Latin.—Linn. Gen. 532. Schreb. 706. Willd. Sp. Pl. v. 4. 856. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1086. Prodr. Fl. Græc. Sibth. v. 2. 265. Ait. Hort. Kew. v. 5. 415. Pursh 647. Juss. 412. Lamarck Illustr. t. 829. Gærtn. t. 91.—Class and order, *Diœcia Monadelphica*. Nat. Ord. *Conifera*, Linn. Juss.

Gen. Ch. Male, Cal. none, except the scales of the bud, resembling a perianth of four leaves. Cor. none. Stam. Filaments numerous, united below into a column, longer than the bud; anthers depressed, blunt, with eight notches, at the edge, splitting all round at the base, and after shedding their pollen becoming flat and peltate, remarkable for their eight marginal segments.

Female, Cal. inferior, of one leaf, close, undivided, entire. Cor. none. Pist. Germen superior, ovate, acute; style none; stigma obtuse. Peric. none, except a spurious incomplete berry, formed of the calyx elongated into a globose juicy coloured sheath, open at the top, at length shrivelling and drying away. Seed one, ovate-oblong, projecting with its summit beyond the berry.

Ess. Ch. Male, Calyx none. Corolla none. Stamens numerous. Anthers peltate, with eight segments.

Female, Calyx cup-shaped, entire. Style none. Seed one, partly enveloped in the pulpy calyx.

Obs. Linnæus properly mentions that the berry of this genus cannot, strictly speaking, be denominated a pericarp. "It is a remarkable species of berry, like which nothing else is to be seen, except perhaps in *Gaultheria*." If the analogy here cited be just, the part in question is a real calyx, not more extraordinary in its change than that of *Blitum*, or of *Merus*, and we have always ventured to term it such, trusting to the analogies of *Juniperus* and *Ephedra* for our support.

1. *T. baccata*. Common Yew. Linn. Sp. Pl. 1472. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 746. (Taxus; Ger. Em. 1370. Matth. Valgr. v. 2. 444. Camer. Epit. 840.)—Leaves linear, two-ranked, crowded, nearly flat. Male flowers globose.—Native of mountainous woods, particularly in the clefts of high calcareous rocks, in various parts of Europe, from Norway to Greece, flowering in March or April. Dioscorides indeed, who calls this tree *σμυλαξ*, speaks of it as an exotic, the *ταξος* of the Romans; but Mr. Hawkins noticed it wild on the rocks of mount Cyllene in Laconia. Thunberg says it is common in Japan. The trunk is straight, of slow growth, with a smooth deciduous bark, and very hard, tough, close-grained wood. Branches spreading horizontally in two directions. Leaves numerous, scattered, crowded, spreading in two rows, nearly sessile, linear, entire, slightly revolute, obtuse with a small point, smooth, of a dark shining green, permanent, about an inch long. Flowers axillary, solitary, nearly sessile, enveloped with imbricated bractæ; the male ones numerous, sometimes two or three together, cream-coloured, half the size of a pea, globose, abounding with pollen; females drooping, their green entire calyx just visible beyond the bractæ. This afterwards assumes the appearance of a bright scarlet berry, the size of a currant, open at the top, where the seed appears. The leaves are very poisonous, and if accidentally eaten by domestic cattle, prove fatal. The

ancients

ancients report that it is dangerous to sleep under this tree. It was formerly much planted in church-yards; and many Yews, perhaps "the tenants of a thousand years," still remain in the northern and Welsh village cemeteries. This was the favourite tree for clipping into any fantastic shape, on which art our old gardeners so much valued themselves; but the art and the material are now nearly alike discarded; and the garden is freed from one of the greatest asylums for vermin, the trim yew hedge.

2. *T. canadensis*. North American Yew. Willd. n. 2. Pursh n. 1. (*T. baccata* β , minor; Michaux Boreal.-Amer. v. 2. 245.)—Leaves linear, two-ranked, crowded, revolute. Male flowers globose, always solitary.—In shady rocky places in North America, flowering in March and April. In Canada. Michaux. Covering a great part of the rocky banks of the Antietum, in Maryland. Under the shade of other trees, it does not rise above two or three feet. Pursh. Michaux describes this species as of humbler growth than the former, spreading; and with smaller flowers and fruit. Willdenow says it is smaller and narrower in all its parts, nor does it alter by culture, and yet a specific distinction is hardly to be detected. The leaves, however, are narrower, smaller, and revolute at the margin. Male flowers always solitary in the bosoms of the leaves.

3. *T. elongata*. Long-leaved African Yew. Ait. ed. 1. v. 3. 415. ed. 2. n. 3. Willd. n. 3. Thunb. Prodr. 117.—Leaves scattered, linear-lanceolate. Branches somewhat whorled. Male flowers cylindrical, with spirally imbricated, very numerous, anthers.—Native of the Cape of Good Hope. Sent to Kew in 1774, and kept in several curious greenhouses in England as well as on the continent, flowering in July. Wild specimens, answering to Thunberg's character of the whorled branches, but without a name, are preserved in the Linnæan herbarium. In these the leaves are scattered, on short broad stalks, flat, coriaceous, somewhat glaucous, occasionally falcate, from one to two inches long. Male flowers axillary, solitary, cylindrical, obtuse, about half an inch in length, their scale-like anthers imbricated, exactly like those of a Fir. The garden plant has leaves half as long again, not glaucous, sometimes opposite on the young branches.

4. *T. montana*. Mountain Peruvian Yew. Willd. n. 4.—"Leaves two-ranked, linear, with a callous point; their upper edge rounded at the base; lower contracted."—Gathered by Humboldt and Bonpland on the mountains of Peru. Akin to *T. baccata*, but differing in the above character of the foliage. The same travellers noticed, in Mexico, what Willdenow judged to be a mere variety of this species, with leaves half as long again.

5. *T. nucifera*. Acorn-bearing Yew. Linn. Sp. Pl. 1472. Willd. n. 5. Ait. n. 3. Thunb. Jap. 275. Kämpf. Am. Exot. 814. t. 815.—Leaves two-ranked, distant, lanceolate, pointed, but half the length of the fruit.—Frequent, according to Kämpfer, in the northern provinces of Japan, flowering in spring, and ripening fruit late in autumn. Thunberg observed it here and there near Nagasaki, and in the island of Nipon. Mr. Aiton says it was cultivated in the greenhouse of Capt. Thomas Cornwall, in 1764. We have never examined this species. Kämpfer describes it as a lofty tree, with many opposite scaly branches; the wood light. Leaves hardly an inch long, one-third of an inch asunder, nearly sessile, tipped with a short point; dark shining green above; glaucous beneath. Female flowers axillary, solitary, dispersed, somewhat quadrangular, their thick fleshy scales becoming a sort of permanent cup at the base of the seed, or nut, which is coated, oval, pointed, above an inch long. The oil of the kernel is esteemed for

culinary purposes. The kernel itself is too astringent to be eaten in general.

6. *T. macrophylla*. Long-leaved Japan Yew. Thunb. Jap. 276. Willd. n. 6. Ait. n. 4. Banks Ic. Kämpf. t. 24. (*Sin*, vulgò Maki, feu *Fon Maki*, id est *Maki legitima*; Kämpf. Am. Exot. 780.)—Leaves scattered, lanceolate, pointless, spreading every way. Fruit stalked.—Common in Japan, flowering in June. Thunberg. Mr. William Kerr brought it from China to Kew in 1804. A greenhouse plant, flowering in July and August. Aiton. Kämpfer describes this as a large and stout tree, whose wood is valued for cabinet work, being not liable to the attacks of insects, or other causes of decay. The leaves are a finger's length, spreading equally in all directions; paler beneath. Male flowers cylindrical. Fruit axillary, stalked, with a pair of awl-shaped revolute scales at the top of the stalk. The seed is oval, the size of a pea, and seems by Kämpfer's figure to be elevated on a partial stalk above the fleshy calyx. Thunberg, however, speaks of the "ovate smooth green berry, turning black in drying, filled by an ovate white seed." Perhaps this may be a coated nut, as in *T. nucifera*.

7. *T. spinulosa*. Spinous-leaved Yew.—Leaves partly opposite or whorled, lanceolate, spinous-pointed, spreading every way. Fruit stalked.—For a specimen of this, said to have been brought by governor Philip from Port Jackson, New South Wales, we are indebted to A. B. Lambert, esq. It very much resembles Kämpfer's plate of the last, in general habit, but the leaves are hardly an inch and quarter long, and have each a spinous point. The stalks of the fruit are axillary, each crowned with a pair of lanceolate, revolute, permanent scales. Fruit oval, elevated on a stalk, which is equal in length to the calyx, composed of several fleshy scales, that envelops it. The size and whole appearance of this fruit and its accompaniments are so precisely like Kämpfer's figure of the last, which indeed they help us to understand, that these two plants must be of the same genus, and are more truly perhaps akin to *T. nucifera*, than to *T. baccata*. On this subject we may expect information hereafter from Mr. Brown; if at least our present plant be really a native of New South Wales.

8. *T. latifolia*. Broad-leaved Cape Yew. Thunb. Prodr. 117. Willd. n. 7.—"Leaves solitary, lanceolate, pointed, smooth."—Found by Thunberg at the Cape of Good Hope.

9. *T. falcata*. Sickle-leaved Cape Yew. Thunb. Prodr. 117. Willd. n. 8.—"Leaves solitary, lanceolate, falcate, smooth."—From the same country. One of our wild specimens of *T. elongata* answers to this definition.

10. *T. tementosa*. Downy Cape Yew. Thunb. Prodr. 117. Willd. n. 9.—"Leaves opposite, lanceolate, downy beneath."—Gathered at the Cape by Thunberg, whose specific characters of these species, except of the last, are not sufficient to distinguish them from the rest. We have seen no specimens.

11. *T. verticillata*. Whorled Japan Yew. Thunb. Jap. 276. Willd. n. 10. (*Ken sin*, item *Sen baku*, vulgò *Inu Maki*, id est *Maki spuria*; Kämpf. Am. Exot. 780.)—Leaves whorled, linear, falcate.—Native of Japan. A tree with dense branches, gradually shorter upward, so as to assume a conical figure, like a Cypress, three fathoms high. Fruit oblong, in two divisions; the lower part resembling mouse-dung; the upper a grain of pepper, in which is loosely enclosed a fleshy, soft, sweetish kernel. Such is Kämpfer's description, by which it is easy to perceive the close resemblance of this fruit to our *T. macrophylla* and *spinulosa*. A specimen from Thunberg, without fructification, in the Linnæan herbarium, answers well to his own description,

tion, having round, smooth, greyish *branches*. Whorls from one to two inches asunder, each of about eight sessile, linear, falcate, entire, smooth, single-ribbed *leaves*, a finger's length, or more; two lines broad; obtuse, or slightly emarginate, at the end; of a dark shining green above; paler beneath.

TAXUS, in *Gardening*, furnishes a plant of the hardy evergreen kind, of which the species mostly cultivated is the common yew-tree (*T. baccata*.) This is a tree which has several varieties, as those with very short leaves, with broad shining leaves, and with striped or variegated leaves.

Method of Culture.—In this tree, the increase may be effected in several ways, as by seeds, and sometimes by layers and cuttings. In the first mode, after having procured a quantity of the yew berries, and divested them of the pulp or mucilage, they should be sown in beds of light earth, either in shallow drills, or scattered over the surface in the autumn or spring season; but the former is the best method, as the plants rise in the following spring; and be covered near an inch deep with light mould, out of the alleys, &c. They require no further care, only to keep the beds clean from weeds before and after the plants come up, and to give occasional waterings in dry weather, in spring and summer, to forward and strengthen the plants in their growth. They should have two years' growth in the seed-bed; then in the autumn or spring be planted out upon four-foot-wide beds, in nursery rows, a foot asunder, to remain two, three, or four years, when some may be planted out finally for hedges, where required; others in the nursery quarters, in rows, two or three feet asunder, to be trained in a suitable manner for the purposes they are intended.

And after growing in the nursery till they obtain from half a yard to four or five feet stature, they may be finally planted out in autumn or spring, for their intended purposes; when they will rise from the ground with a large spread of roots. They should be planted in their places as soon after removal as possible, giving each plant a good watering at the time.

In the future culture, those trained in hedges, &c. must be clipped or cut in annually, once or twice in the summer; and those in the shrubberies and rural plantations have the lower branches pruned up occasionally to a single stem; but the head should generally be permitted to spread agreeably to its natural mode of growth, except just reducing any considerable rambling branch, &c.

But the striped or variegated yews, and other varieties, should be increased by layers, slips or cuttings, as they are rarely permanent by seeds. The layers should be made from the young shoots of not more than a year or two old, being laid down in spring, summer, or early in autumn, when many of them will take root, and in one or two years be fit for planting off into nursery rows.

And the slips and cuttings should be made by cutting or slipping off a quantity of the one-year's shoots, divesting them of the lower leaves, and planting them in a shady border thick together, in small trenches, in the early spring or autumn, giving water at planting, and afterwards occasionally in dry hot weather. They will be well rooted in two years, and be fit for being planted out into wide nursery rows, or in any other similar manner.

All these plants may be employed as ornamental evergreens, and as forest-trees; and they were formerly much used in hedges and trained figures: they have a good effect in shrubberies among others of the evergreen tribe, being permitted to assume their natural growth, in common with other trees and shrubs; and also when planted as detached standards, in extensive distant opens of grass-ground, in

parks, and the sides of hills, &c.; likewise when introduced as forest-trees in timber plantations of the evergreen kind. See PLANTATION.

The different sorts of hedges and figure-works which were formerly in so high repute in gardens and pleasure-grounds, are now almost wholly in disuse, these being at present laid out in a more open and rural manner, so as to have a greater imitation of nature, and a more full display of their several quarters and parts, as the lawn, walks, and other places, together with the various plants belonging to them.

Single yews are now even hardly ever admitted in modern designs by way of ornament, but these trees, in their natural growths, are desirable for introducing into large plantations of the durative kind, for the sake of increasing the variety; and though some persons reject them in consequence of their poisonous nature, and gloomy mournful aspect, others admire them for such solemn appearances, and think they afford a remarkably fine contrast with the other more lively evergreens. There can be no doubt that the leaves, especially when withered, or dried a little, are of a poisonous quality; besides, the tree has had the title of the *deadly yew* given to it by some, and been looked upon as an emblem of mortality, and on that account planted in church-yards, to remind people of their latter end. That accidents have frequently arisen to cattle, of both the horse and cow kind, from eating the green leaves and tender shoots, but more particularly when in the above states, is certain. Therefore, as the cuttings or clippings of this sort are often liable to be eaten with greediness by some cattle, particularly cows, even when they have lain in the sun for a day or two, and are become half dried, it is proper and necessary that they should be either carefully destroyed by fire, or put quite out of the way of all sorts of animals, and not, as is too frequently the practice, be carelessly thrown over the walls or hedges, into the roads, lanes, or on the rubbish heaps, where cattle frequent.

The best sizes of yew plants are probably from two or three, to five or six feet in height; but those of seven or eight may be removed with balls of earth about their roots, and be used for particular purposes and occasions. Watering at the time of planting them is constantly requisite.

TAXUS, in *Zoology*, the *URSUS Males*, or common *Badger*; which see.—Also, a name given by Kæmpfer to the hyæna of the ancients. See *CANIS Hyæna*, and *HYÆNA*.

TAY, in *Geography*, is a river in Perthshire, Scotland, considered as the greatest of the Scottish rivers, has its source in the western extremity of the county, in the district of Breadalbane, on the frontiers of Lorn, in Argyleshire; but has not the appellation of Tay till it issues from the lake of that name. At its source it bears the name of Fillan; and descending in a circuitous course of eight or nine miles through a valley, to which it gives the name of Strathfillan, it falls into Loch Dochart. This lake, about three miles in length, has an ancient castle upon an island, overhung by a huge promontory; the whole embowered with wood, so as to have a most romantic appearance. Issuing from Loch Dochart, the river retains that name, and gives the appellation of Glen-Dochart to the vale through which it runs. At the eastern extremity of this valley, the water is again detained in its course; and being augmented by the river Lochay, the united streams form one of the most beautiful of the Scottish lakes, called Loch Tay. Issuing hence, the river assumes the name of the lake, which name it retains till it mingles with the waters of the ocean. The valley through which it passes may be considered as the paradise of the Highlands. On Loch Tay, and the river for some

some miles below it; the banks are richly cultivated, or covered with beautiful plantations, the whole overlooked and sheltered by mountains towering to the clouds; among which rises the lofty Benlawers, the third mountain in point of height in the island. Here, near the village of Kenmore, is the magnificent seat of the earl of Breadalbane, called Taymouth; and in this valley, although the parishes are twenty, thirty, or forty miles in extent, several parish-churches are situated in a tract of a few miles; a circumstance which demonstrates the discernment of the clergy in ancient times in selecting their place of residence. After leaving the lake about two miles, the Tay acquires a great increase from the waters of the Lyon; at Logierat it receives the united streams of the Garry and the Tummel, and becomes a river of uncommon size and beauty. Near Dunkeld it is increased by the waters of the Bran, and receiving in its course the Isla, with its tributary streams from the east, and the Almond from the west, proceeds by Perth between the hills of Kinnoul and Moncrieff, till it meets the Earn, after which it proceeds eastward, forming the estuary or Frith of Tay; which expands to the breadth of three miles, but contracts to two miles as it approaches Dundee, about eight miles below which, it pours its waters into the German ocean. The hills of Kinnoul and Moncrieff afford extensive prospects; that from the latter is denominated by Pennant the "Glory of Scotland." The Tay is navigable as far as Newburgh, in Fife, for vessels of 500 tons; and vessels of considerable size can go up as far as Perth. The Frith of Tay is not so commodious as that of the Forth; but from the Buttonnells or Barray sands to Perth (an extent of nearly forty miles), the whole may be considered as a harbour; having the county of Fife on one side, and those of Angus and Perth on the other. There are fewer great falls of water on the Tay than in most other rivers which rise in a highland district; but it possesses several cascades of considerable height, particularly at the Linn of Campsie, near its junction with the Isla, where the water is precipitated over a huge basaltic dike into a pool of great depth.—*Beauties of Scotland*, vol. iv. Perthshire, 1806. *Gazetteer of Scotland*, 1806.

TAY, *Loch*, a lake in Perthshire, Scotland, extends about fifteen miles in length from the village of Killin, its western extremity, to its eastern termination at the village of Kenmore; its breadth is only from one to two miles. Its depth varies in different parts, from fifteen to a hundred fathoms. The banks on both sides are fertile, and finely diversified by the windings of the coasts and the varied appearances of the mountains. On a small promontory near the eastern extremity, are the church and village of Kenmore, near which, on a small island covered with trees, stand the ruins of a priory, which was dependent on the religious establishment of Scone. It was founded, in 1122, by king Alexander I., who deposited there the remains of his queen Sybilla, the natural daughter of Henry I. of England. On the death of Alexander the priory was more liberally endowed, that the monks might perform masses for the repose of his soul, as well as for that of his queen. The loch abounds with salmon, pike, perch, eels, charr and trout. The salmon are peculiarly excellent; the fishery for which commences in December, and ends on the 26th of August. The earl of Breadalbane has the exclusive right of fishing there at all seasons. This privilege was originally granted for the purpose of supplying fish for the monks of the priory, and at the dissolution was, with the island, claimed by this noble family. The waters of this lake have at times suffered violent and unaccountable agitation. An ample account of one of these phenomena, which

occurred on Sunday, September 12, 1780, is published in the first volume of the *Transactions of the Royal Society of Edinburgh*. It was written by Mr. Fleming, late minister of Kenmore. He states, that "about nine o'clock in the morning the water was observed to retire about five yards within the ordinary boundary, and in four or five minutes to flow out again. In this manner it ebbed and flowed successively three or four times within the space of a quarter of an hour, when all at once the water rushed from the east and west in opposite currents, and rose in the form of a great wave to the height of five feet above the ordinary level, leaving the bottom of the bay dry to the distance of between ninety and an hundred yards from its natural boundary. When the opposite currents met, they made a clashing noise and foamed; and the stronger impulse being from the east, the wave, after rising to its greatest height, rolled westward, but slowly diminishing as it went, for the space of five minutes, when it wholly disappeared. As the wave subsided, the water flew back with some force, and exceeded its original boundary four or five yards; then it ebbed again about ten yards, and again returned, and continued to ebb and flow in this manner for the space of two hours, the ebbings succeeding each other at the distance of about seven minutes, and gradually lessening, till the water settled into its ordinary level. During the whole time that this phenomenon was observed, the weather was calm. It could scarcely be perceived that the direction of the clouds was from north-east." On the 13th of July, 1794, the loch experienced agitations similar to those described by Mr. Fleming, but they were neither so violent nor so long continued.—*Beauties of Scotland*, vol. iv. Perthshire.

TAY, a river of Ireland, in the county of Waterford, which runs into the sea, 7 miles W.N.W. from Dungarvan bay.

TAYA, a river of Austria, which rises near Schweigers, passes by Drosendorf, and enters Moravia, passes by Znaym, Laab, &c. and joins the Marsch, 4 miles N.N.E. of Hockenau.—Also, a small island in the Indian sea, near the west coast of Siam. N. lat. 7° 38'. E. long. 98° 30'.

TAYABO, a town on the east coast of the island of Celebes, in Gunong-Tellu bay. S. lat. 1° 10'. E. long. 121° 30'.

TAYASAN, a town on the east coast of the island of Negros. N. lat. 10° 18'. E. long. 123° 3'.

TAYBA, a ruined town in the deserts of Syria, which shews in its present state, evident marks of its former magnificence.

TAYECUA, a town of South America, in the province of Darien; 30 miles W. of St. Marie de Darien.

TAYGETA, in *Ancient Geography*, a river of the Peloponnese, in Laconia.

TAYGETUS, a mountain of Laconia, S.W. of Brysee, being a portion of a small chain of mountains on the promontory of Tenarus, on the frontiers of Arcadia. It was famous for the abundance of its game. On this mountain was a place consecrated to the sun, called by Pausanias "Talet." Here they sacrificed, among other victims, horses.

TAYKYATT, a long and straggling town of the Birman empire, on the W. side of the Irawaddy; 5 miles W.N.W. of Yeoungbenzah.

TAYL, in *Heraldry*. See TAIL.

TAYLOR, Brook, LL.D. and F.R.S., in *Biography*, an eminent mathematician, was born of a good family, at Edmonton, near London, in the year 1685. In early life he devoted himself to music, drawing, and painting, in which he was reckoned to excel. At the same time he pursued his

his classical studies and mathematics under a private tutor; and in 1701, at the age of 15, he was entered a fellow-commoner at St. John's college, in the university of Cambridge. Such was his assiduity in the prosecution of mathematics, that in 1708 he composed his treatise "On the Centre of Oscillation," which was published in the *Phil. Transf.* In the next year he took his degree of bachelor of laws, and in 1712 he was elected fellow of the Royal Society. By a letter addressed to Mr. Machin, dated in this year, it appears that he had then given a solution of Kepler's famous problem, pointing out its importance and use. He also at the same period presented to the Society three papers, *viz.* "On the Ascent of Water between two Glass Planes;" "On the Centre of Oscillation;" and "On the Motion of a stretched String." In consideration of his services to the Society, and distinguished qualifications for the office, he was elected their secretary in 1714, taking in the same year his degree of doctor of laws at Cambridge. In 1715, he published his "Methodus Incrementorum;" a curious essay, preserved in the *Phil. Transf.* entitled, "An Account of an Experiment for the Discovery of the Laws of Magnetic Attraction;" and also a treatise, of high value and reputation, "On the Principles of Linear Perspective." His correspondence this year with count de Montmort on the tenets of Malebranche was ably conducted, and gained for him an eulogy from the French academy; and in 1716, on his visit to Paris, he was treated with great personal respect. Upon his return to London, in 1717, he composed three treatises, published in the 30th volume of the *Phil. Transf.*; the titles of which are, "An Attempt towards an Improvement of the Method of approximating in the Extraction of Roots of Equations in Numbers;" "A Solution of Demoiivre's 15th Problem, with the Assistance of Combinations and infinite Series;" and "A Solution of the Problem of G. G. Leibnitz proposed to the English." His health being impaired by intense application, he was obliged to seek relief at Aix-la-Chapelle. Upon his return, in 1719, he directed his attention to studies very different from those to which he had been accustomed; and the fruits of these studies have been found among his papers by his grandson sir William Young, in detached fragments of a treatise on the Jewish sacrifices, and a dissertation on the lawfulness of eating blood. His leisure hours were still devoted to the application of mathematics in the improvement of the arts; and with this view he revised his treatise on Linear Perspective, which appeared in a new and enlarged form. Drawing was also a favourite amusement. His treatise on Linear Perspective, which has been held among mathematicians in the highest estimation, produced at this time a controversy, which terminated in a very serious misunderstanding, between him and J. Bernouilli. This treatise, abstruse to those who consult it for mere practical purposes, was rendered more plain and perspicuous by Mr. Kirby, in an edition, entitled "Brook Taylor's Perspective made easy." Our author's answer to Bernouilli is preserved in the 30th volume of the *Phil. Transf.* Soon after his return to England in 1721, he published the last paper that appears with his name in the *Phil. Transf.* entitled "An Experiment made to ascertain the Proportion of Expansion of Liquor in the Thermometer, with regard to the Degree of Heat."

Dr. Taylor was twice married: his second wife was a daughter of John Sawbridge, esq. of Olantigh in Kent. On the death of his father, in 1729, he succeeded to the family estate of Biffons in Kent, and in the following year his wife died in child-bed. About this time he probably wrote the essay, entitled "Contemplatio Philosophica,"

published by sir W. Young in 1793. But though his mind might have thus obtained temporary relief, he survived his wife little more than a year, and died of a decline in the 46th year of his age, December 1731. "I am spared," says his descendant, "the necessity of closing this biographical sketch with a prolix detail of his character, in the best acceptance of duties, relative to each situation of life in which he was engaged; his own writings, and the writings of those who best knew him, prove him to have been the finished Christian, gentleman, and scholar." Life by his grandson, sir William Young, prefixed to his Posthumous Works.

TAYLOR, JEREMY, an eminent divine and prelate of the established church in Ireland, was the son of a barber at Cambridge, where he was born in the early part of the 17th century. At the age of 13 he was admitted at Gonville and Caius college in the university of that place, where he remained till he took the degree of M.A. Having taken orders, he occasionally preached in London, and obtained by the interest of archbishop Laud, in 1636, a fellowship of All Souls' college, Oxford. Here he resisted attempts that were made to profelyte him to popery, and became more established in Protestant principles. Laud appointed him one of his chaplains, and procured for him the rectory of Uppington, in which he settled about the year 1640, at which time he surrendered his fellowship and married. In 1642 he was chaplain in ordinary to Charles I., and served his cause by writing in defence of the church of England. When the parliament became victorious, his living was sequestered, and he retired into Wales, where he was kindly received by the earl of Carbery, of Golden Grove, near Llandilo, in Carmarthenshire; under whose protection he exercised his ministry, and kept a school for the support of his family. In this state of retirement, he composed those discourses, which caused him to be held in high estimation, as one of the first writers in the English language, "with respect to fertility of conception, eloquence of expression, and comprehensiveness of thought." At this period the death of three hopeful sons disturbed his tranquillity, and rendered it necessary for him to change the scene and to remove to London, where he exposed himself to considerable danger by officiating in a private congregation of loyalists. Invited by Edward lord Conway to his seat at Portmore in the county of Antrim, he remained in Ireland until the Restoration. On that event he came over to England, and in January 1660-1, his services were recompensed by the promotion to the sees of Down and Connor. He was also made privy-counsellor of Ireland, and appointed to the administration of the bishopric of Dromore, and honoured with the office of vice-chancellor to the university of Dublin. In these high and responsible stations he paid sedulous attention to his official duties, exhibited an example of piety, humility, and charity; and employed so great a part of his income in doing good, both privately and publicly, that when he died at Lisburne in 1667, he left only moderate portions to his three daughters. His person was comely, his manners were polite, his voice was melodious, and his conversation was agreeable. Of his works, which were numerous, consisting chiefly of sermons and devotional pieces, and printed in four, and also in six volumes, folio, the most remarkable is entitled, "Theologia Eclectica, or a Discourse on the Liberty of Prophecy; shewing the unreasonableness of prescribing to other men's faith, and the iniquity of persecuting different opinions," &c. first published in 1647. The author, when this book was written, belonged to a vanquished and persecuted party; and he strongly and boldly pleads for liberty of conscience, and the rights of individuals to judge for themselves in matters of religion.

religion. This work, considering the time in which it was written, and the connections of the author, indicates a very enlightened mind with regard to the subjects of discussion; and it is perused with no small degree of interest in the present period of greater knowledge and liberality. With respect to toleration, however, we observe, that he limits it to such doctrines as are not inconsistent with society or the public good;—a limitation which is capable of being much misconstrued and misapplied. Having asserted, as a first principle, that “the duty of faith is completed in believing the articles of the Apostles’ creed,” he could not consistently approve the imposition of stricter creeds. Of the Athanasian creed he thus speaks: “If I should be questioned concerning the symbol of Athanasius, I confess I cannot see that moderate sentence and gentleness of charity in his preface and conclusion, as there was in the Nicene creed. Nothing there but damnation and perishing everlastingly, unless the article of the Trinity be believed, as it is there with curiosity and minute particularities explained. Besides, if it were considered concerning Athanasius’s creed, how many people understand it not, how contrary to natural reason it seems, how little the scripture says of those curiosities of explication, and how tradition was not clear on his side for the article itself, much less for those forms and minutes,—and after all this, that the Nicene creed itself went not so farre, neither in article, nor anathema, nor explication, it had not been amiss if the final judgment had been left to Jesus Christ.”

This celebrated work did not escape invidious criticism and severe animadversion. Among others we may mention Anthony Wood, who, with censurable illiberality, suggested, that Taylor in this book, and Hales in his tract on Schism, employed their arguments as a stratagem by way of raising factions among the Presbyterians, and dissolving their union. The most popular of Taylor’s other writings, have been his “Golden Grove, or Manual of daily Prayers;” his treatise on “Holy Living and Dying;” and his “Ductor Dubitantium, or Rule of Conscience.” Dr. Dodwell long since observed, and not unjustly, that “Dr. Taylor, in his voluminous writings, said many lively things, which will not bear a strict examination.” *Biog. Brit. Gen. Biog.*

TAYLOR, JOHN, D.D. a learned and highly respectable divine among Protestant Dissenters, was born in the year 1694, at or near Lancaster. After having received his education at Whitehaven under Dr. Dixon and others, he was nominated by one of the Disney family to the chapel of Kirkstead, in Lincolnshire, exempt from ecclesiastical jurisdiction, and which had been occupied from the latter end of the preceding century by dissenting ministers. Here he lived, on a small salary aided by a school, for 18 years; and laid a foundation for the theological celebrity, which he afterwards acquired by a diligent study of the scriptures in their original languages. In this obscure and retired situation he did not escape notice; and in the year 1733, he complied with an invitation from the Presbyterian congregation at Norwich. To his congregation, which had been before his settlement served by Calvinistic ministers, he recommended the perusal of Dr. Clarke’s *Scripture-Doctrine of the Trinity*. His first publication was “*A Prefatory Discourse to Mr. Joseph Rawson’s Case*,” who, in 1736, had been excluded from communion with the congregational church at Nottingham, for refusing his assent to a declaration required of him concerning the Trinity; in which he ably defended the right of Christians to deduce their faith from the scriptures, without the intervention of creeds and subscriptions. His first avowed attack upon Calvinistic theology, was the publication of his “*Scripture-Doctrine of*

Original Sin,” which first appeared in 1740. This excited alarm and animadversion. (For an account of this controversy, see the article *Original Sin*.) Dr. Taylor’s supplement was published in 1741. This was succeeded, in 1745, by “*A Paraphrase on the Epistle to the Romans, with a Key to the Apostolic Writings*.” This “*Key*” was well received, and has been highly commended. The late learned Dr. Watson, bishop of Llandaff, has given it a place in his “*Theological Tracts*,” and archdeacon Paley recommends a careful perusal of the Paraphrase on the Romans to candidates for priests’ orders. The labours of his subsequent years produced several small tracts, and particularly his “*Scripture-Doctrine of Atonement*,” but his opus majus, as we may justly denominate it, was his “*Hebrew Concordance*,” in folio, the first volume of which appeared in 1754, and the second in 1757. This work, which does immortal honour to the critical skill and indefatigable assiduity of the author, was encouraged by a great number of subscribers, among whom we may enumerate twenty-two English, and fifteen Irish bishops. Soon after the publication of this performance, the author was presented by the university of Glasgow with the degree of D.D. In 1754 he published a pamphlet, entitled “*The Lord’s Supper explained upon Scripture Principles*,” and in 1757 appeared a defence of infant baptism, entitled “*The Covenant of Grace*.” Dr. Taylor was happily situated at Norwich, and received every testimony of respect to which his learning and character entitled him; but a scene of more public and general usefulness was opened to him in the year 1757, when he was invited to supply the place of divinity-tutor at the newly-founded academy of Warrington, in Lancashire. But here his situation was rendered unpleasant to him; and some events occurred which affected his health and spirits. Although he performed his official duties for some time amidst the disquiets which he experienced, he was at length carried off, by an unperceived death, during the night of March 5, 1761, at the age of 66 years. At Warrington he published two pamphlets, *viz.* “*An Examination of the Scheme of Morality advanced by Dr. Hutcheson, late Professor of Morality in the University of Glasgow*,” and “*A Sketch of Moral Philosophy*,” for the use of his class. He also prepared for the press “*The Scripture Account of Prayer, in an Address to the Dissenters in Lancashire*,” in consequence of the introduction of a liturgy at Liverpool, an innovation in the accustomed mode of worship among Dissenters which he disapproved. His posthumous work, entitled “*A Scheme of Scripture Divinity*,” was published by Mr. Richard Taylor of Norwich, his eldest surviving son; and it was held in such estimation by the late bishop of Llandaff, as to form a part of his *Collection of Tracts*. As a preacher, Dr. Taylor was plain and simple in his language, but dignified and impressive; and he excelled in a critical explanation of difficult passages of scripture. He had the merit of introducing into the congregation at Norwich a spirit of liberal enquiry, which, we are informed, still continues. *Memoir on the Life of Dr. John Taylor of Norwich.*

TAYLOR, JOHN, LL.D., the son of a barber at Shrewsbury, was born about the year 1703, and distinguished himself as a scholar and critic. After a course of preparatory education in his native town, he was entered at St. John’s college in Cambridge, and became a fellow of it in the year 1730, in which year he published two Latin academical orations. In 1732 appeared proposals for an edition of *Lyfias*. He was first librarian and afterwards registrar of the university. His “*Lyfias*,” Gr. and Lat., with the conjectures of Markland, was published from the press of

Bowyer, in 1739; and a new edition, with Taylor's version and notes, was printed at Cambridge in the following year. Upon taking his degree of LL.D. he delivered and published a dissertation under the title of "Commentarius ad legem decemviralem de inope debitore in partes dissectando." In 1743, he published "Orationes duæ; una Demosthenis contra Meidiam; altera Lycurgi contra Leocratem," Græc. and Lat. with notes and emendations; and in the following year, "Marmor Sandvicense, cum Commentario et Notis," being a dissertation on an Athenian marble brought to England by lord Sandwich, bearing the oldest inscription of known date.

In 1741, Dr. Taylor had been admitted an advocate in Doctors' Commons, and in 1744 he was made chancellor of Lincoln. He afterwards took orders, and printed a sermon preached at Bishop-Stortford in 1749. He was presented to the archdeaconry of Buckingham, to the rectory of Lawford, Essex; and in 1757 to a residentiaryship of St. Paul's. In 1755, still prosecuting his legal studies, he published "Elements of the Civil Law," 4to. reprinted in 1769. An abridgment of this learned work, entitled "A Summary of the Roman Law," was published in 1773.

Dr. Taylor held also the offices of commissary of Lincoln and of Stowe: he was a member of the Royal and Antiquarian Societies; and of the latter he was one of the vice-presidents. At the time of his death, his long-promised edition of Demosthenes was just finished, in two vols. 8vo. at the university press, Cambridge; and the notes were afterwards added, together with part of an appendix to Suidas. The character of Dr. Taylor was that of an amiable and disinterested man; and the world was deprived of his learned labours in April 1766. To the works already mentioned, we may add some remarks inserted in Foster's "Essay on Accent and Quantity," and various pieces of poetry, printed in the Gentleman's Magazine, and in Nichols's "Select Collection of Poems." Anecd. of Bowyer. Month. Rev. Gen. Biog.

TAYLOR, HENRY, A.M. a very respectable clergyman of the established church, was the son of William Taylor, merchant of London, and born at Southweald, in Essex, in May 1711. The rudiments of his education he received at Mr. Newcome's school, in the parish of Hackney, and there he formed an early friendship with Mr. John Hoadly, son of Dr. Benjamin Hoadly, bishop of Winchester. From Hackney he removed to Queen's college, in the university of Cambridge, and having completed his education with a view to the church, he took orders, and commenced the exercise of his ministerial duties as a preacher with singular acceptance. His talents and acquirements, as well as his voice and manner of delivery, which were peculiarly pleasing, recommended him to public notice, and he ranked high in the estimation of those friends with whom he intimately associated. His first preferment was the rectory of Whitfield, in Oxfordshire, which he held for a minor. In 1755 he was presented by bishop Hoadly to the rectory of Crawley, in Hampshire, which he afterwards held in connection with the vicarage of Portsmouth, in exchange for a living in Hampshire, which he had held with Whitfield. He married Miss Christian Fox, daughter of the Rev. Francis Fox, rector of St. Mary's, Rotherhithe, who died in the year 1769; and by her he had four sons and two daughters. His course of literary and clerical labour terminated in April, 1785, and he was interred at Crawley.

Having recited the few particulars which we could collect concerning the private life of Mr. Taylor, we shall now subjoin a list of his publications, some having his name and others

being anonymous. In 1760 he published "An Essay on the Beauty of the Divine Economy; being the Substance of a Sermon (with many and large Additions) preached at the Visitation of the Lord Bishop of Winchester, held by the Worshipful and Reverend Dr. John Hoadly, Chancellor of the Diocese, on Tuesday September 18, 1759, at the cathedral Church of Winchester, and published at the Desire of Mr. Chancellor and the Clergy."—"A full Answer to a late View of the internal Evidence of the Christian Religion, in a Discourse between a rational Christian and his Friend," 1771.—"A Tract against Warburton," 1772.—"Confusion worse confounded, Rout on Rout; or the Bishop of Gloucester's Commentary upon Rice or Arise Evans's Echo from Heaven, examined and exposed by *Indignatio*," London, 1772. Anonymous. "Two Letters; viz. 1. A Letter to the Earl of Abingdon, in which His Grace of York's Notions of Civil Liberty are examined by *Liberalis*, published in the London Evening Post, November 6, 1777. 2. *Vera Icon*; or a Vindication of His Grace of York's Sermon, preached on February 21st, 1777; proving it to contain a severe Satire against the Ministry, and a Defence of civil and religious Liberty, upon the well-known Principles of Whiggism; in answer to a Letter from *Liberalis* to the Earl of Abingdon, by *Mythagogus Candidus*."—"The Apology of Benjamin Ben Mordecai to his Friends, for embracing Christianity; in seven Letters to Elisha Levi, Merchant of Amsterdam; with Notes and Illustrations, by the Author and the Editor." Lond. 1771. 1773, 1774, 4to. The first of these letters contains an account and examination of the various opinions among Christians, concerning the nature and person of Christ. In the second, third, and fourth letters, it is proposed to shew from scripture, that the Logos was the angel of the covenant, and to prove the same from the most approved commentators on scripture, both ancient and modern, both Jewish and Christian; and to demonstrate that Jesus was the Messiah. The fifth, sixth, and seventh letters contain preparatory principles to the Christian scheme of redemption; giving the scheme of Christianity itself, and shewing it to be one, plain, regular, and consistent system of divine economy, from the beginning of the world to the end; and containing proofs, illustrations, answers to objections, and an examination of Mr. Hume's notion of miracles.—"Thoughts on the Nature of the Grand Apostacy, with Reflections and Observations on the Fifteenth Chapter of Mr. Gibbon's History of the Decline and Fall of the Roman Empire; to which are added three dissertations: 1. On the Parousia of Christ; 2. On the Millennium; 3. On the late Rev. Mr. Richard Wood, on Prophecy," 1781.—"Farther Thoughts on the Nature of the Grand Apostacy of the Christian Churches, foretold by the Apostles; with Observations on the Laws against Heresy, the Subscription to Articles of Human Composition, and other Subjects of the utmost Importance to the Religion of Protestants, and to Christianity in general," 1783.—"Considerations on Ancient and Modern Creeds compared; the Supremacy of the Father; the personal Existence of the Holy Spirit; the Pre-existence of Christ and his Divinity, &c." published after the author's death by his son, the Rev. Henry Taylor, rector of Spridlington, Lincolnshire, 1788.

Mr. Taylor, who was of a sprightly, cheerful disposition, occasionally amused himself in writing verses; some of which, particularly his "Paradise Regained," are published in Doddsley's Collection.

On Mr. Taylor's principles and character it is needless to enlarge. His conduct in private and social life corresponded to his clerical profession: to the sentiments of bishop Hoadley, in church and state, he was invariably attached; he joined the petitioning

petitioning clergy in their application for an enlargement of the terms of conformity; and he avowed himself on all occasions, without disguise, the friend and advocate of civil and religious liberty. In his theological opinions, he considered himself as coinciding more nearly with Apollinaris, than with any other.

TAY-MING, in *Geography*, a city of China, of the first rank, in Pe-tche-li; 232 miles S.S.W. of Peking. N. lat. $36^{\circ} 20'$. E. long. $114^{\circ} 49'$.

TAYNG, a town of Corea; 25 miles S.E. of Haimen.

TAYWAN, or **TAI-OUAN**, the capital of *Formosa*; which see.

TAZ, a river of Russia, which rises from two lakes, Ku and Din, and runs into the Tazovskaia gulf, N. lat. $67^{\circ} 35'$. E. long. $80^{\circ} 14'$.

TAZABUCO, a town of Peru; 46 miles E.N.E. of La Plata.

TAZATA, in *Ancient Geography*, an island of the Caspian sea, near the coast of Hyrcania. Pliny. It is called Talca by Ptolemy, and Talga by Mela.

TAZEE, in *Geography*, a town of Candahar; 70 miles E. of Candahar.

TAZEWELL, a post-town of Tennessee; 517 miles W.S.W. of Washington.

TAZINA, in *Ancient Geography*, a town of Asia, in Media.

TAZLA, or **SALATO**, in *Geography*, a lake of Asiatic Turkey, 36 miles long, and 2 broad; 30 miles N. of Cogni.

TAZLA, a town of Asiatic Turkey, in Caramania; 28 miles N. of Cogni.

TAZOVSKAIA, a gulf or bay in the Obkskaia gulf, formed by the waters of several rivers of Siberia, and joined to the Obkskaia gulf, about 140 miles in length, and 3 in breadth. N. lat. $67^{\circ} 40'$ to 69° . E. long. 76° to 80° .

TAZREE, a town of Persia, in the province of Laristan; 15 miles N.E. of Tarem.

TAZUS, **TACHELY**, in *Ancient Geography*, a town in the interior of the Tauric Chersonesus, E. of Portacra, mentioned by Ptolemy.—Also, a town of Asiatic Sarmatia, upon the northern coast of the Euxine sea.

TAZZETTA, in *Botany*, the specific name chosen by Linnæus, who spells it incorrectly, for the Polyanthus Narcissus. (See **NARCISSUS**.) The word is Italian for a small cup, and De Theis supposes it was first applied in Italy to this flower, which is much cultivated there, and usually imported from thence, in its highest perfection, by our florists. Still we do not see how Linnæus came to adopt this name, nor, indeed, how it fell in his way.

TCHA. See **TEA**.

TCHA, or *Cangua*, in *Geography*. See **CANGA**.

TCHABA, a town of Asiatic Turkey, in Natolia; 18 miles E. of Boli.

TCHABAR, a river of Chinese Tartary, which runs north into the Songarie.

TCHABISCHI, a town of Russia, in the government of Irkutsk, on the Amur; 40 miles N.N.E. of Stretensfk.

TCHACAHAMAR, a town of Thibet; 10 miles W. of Orto.

TCHACAOSO, a town of Thibet; 25 miles S. of Chatcheou.

TCHACA-TCHOUTCHI, a town of Thibet; 30 miles N.W. of Tchontori.

TCHACA-TOHOL, a town of Chinese Tartary, in the country of Hami; 15 miles N.W. of Quatcheou.

TCHADOBSKO, a town of Russia, in the government of Tobolsk, on the Tunguska; 212 miles E. of Eniseisk.

TCHAGANSKOI, a fortress of Russia, on the Ural; 16 miles S. of Uralsk.

TCHAGODO, a town of Russia, in the government of Novgorod, on the lake Voz; 240 miles N.E. of Novgorod. N. lat. $60^{\circ} 30'$. E. long. $38^{\circ} 44'$.—Also, a river of Russia, which rises near Suchotzkoi, in the government of Novgorod, and runs into the Mologa, 16 miles N. of Ustiuzna.

TCHAHAN HOTUN, a town of Chinese Tartary; 260 miles N. of Peking. N. lat. $43^{\circ} 58'$. E. long. $117^{\circ} 20'$.

TCHAHAN Hamer, a town of Chinese Tartary; 38 miles S.W. of Coucou.

TCHAHAN Soubarkan Hotun, a town of Chinese Tartary; 163 miles N.N.E. of Peking. N. lat. $41^{\circ} 38'$. E. long. $118^{\circ} 44'$.

TCHAHASOU HOTUN, a town of Chinese Tartary; 683 miles N.N.E. of Peking. N. lat. $49^{\circ} 34'$. E. long. $127^{\circ} 42'$.

TCHAHAI, a town of Persia, in the province of Chorasfan, or Khorassan; 258 miles N. of Herat.

TCHAIIA, a river of Russia, which runs into the Lena, near Tchamska, in the government of Irkutsk. N. lat. $58^{\circ} 5'$. E. long. $109^{\circ} 34'$.

TCHAIKAN, a town of Corea; 28 miles W. of Outchuen.

TCHAI-YAM, a river of China, which joins the Lo, 15 miles W.S.W. of Pao-king.

TCHAKAN-TOTOHO KIAMEN, a post of Chinese Tartary, in the country of the Monguls; 18 miles S.E. of Kara-Hotun.

TCHAKET, a town of Asiatic Turkey, in Aladulia; 15 miles N. of Adana.

TCHAKTELA, a town of Asiatic Turkey, in Caramania; 27 miles N. of Akshehr.

TCHAL, a town of Kurdistan, or Curdistan; 28 miles E. of Amadiéh.

TCHALBISCHEVO, a town of Russia, in the government of Tobolsk; 20 miles S. of Eniseisk.

TCHALMOZA, a town of Russia, in the government of Olonetz, on the north-east coast of lake Onezskoe; 32 miles S.E. of Povenetz.

TCHAM, a town of Corea; 420 miles E. of Peking.

TCHAMDSOU-TIGAC, a lake of Thibet, about 36 miles in circumference. N. lat. $31^{\circ} 30'$. E. long. $81^{\circ} 26'$.

TCHAMNAGOM-DOU, a lake of Thibet, about 36 miles in circumference. N. lat. $30^{\circ} 50'$. E. long. $93^{\circ} 54'$.

TCHAMSKA, a town of Russia, in the government of Irkutsk; 64 miles E.N.E. of Kirensk.

TCHAM-TCHIM HOTUN, a town of Corea; 415 miles E. of Peking. N. lat. $40^{\circ} 9'$. E. long. $124^{\circ} 46'$.

TCHAM-TIËN, a town of Chinese Tartary; 43 miles N.W. of Siao-ku-leou.

TCHAMTOU, a town of Thibet; 54 miles S.W. of Contchoudfong.

TCHANG, a lake of China, about 20 miles in circumference; 40 miles N.E. of Tein-tcheou.

TCHANG-CHAN, or **CHAN-SAN**, a small island in the Chinese sea, and most southerly of those called Mi-a-tou; 18 miles N.W. of Teng-tcheou.

TCHANG-FONG, a town of Corea; 63 miles E.S.E. of King-ki-tao.

TCHANG-HOA, a town of China, of the third rank, in the isle of Hainan; 42 miles S.W. of Tchen-tcheou.

TCHANG-ING, a town of Corea; 40 miles S. of Kang.

TCHANG-KIA-KEOU, a gate on the great wall, which separates China from Tartary, in the northern part of Pe-tche-li, the principal passage by which the Tartars enter China; 90 miles N.N.W. of Peking.

TCHANG-PING, a town of Corea; 15 miles E. of Koang-tcheou.—Also, a city of China, of the second rank, in Pe-tche-li; 20 miles N.N.W. of Peking. N. lat. $40^{\circ} 14'$. E. long. $115^{\circ} 37'$.

TCHANG-SING, a town of Corea; 35 miles S. of Koang-tcheou.

TCHANG-SONG, a town of Corea; 33 miles N.W. of Kang-tcheou.

TCHANG-TCHA, a city of China, of the first rank, in Hou-quang, on the Heng river. The inhabitants of this city have given occasion to a great festival, which is celebrated in the fifth month throughout the empire. The mandarin who governed this city, and was much esteemed and beloved by the people for his probity and virtue, happening to be drowned in the river, they instituted a festival to his honour, which is celebrated by sports, and feasts, and fights upon the waters, as if they intended to search for the mandarin, the object of their love and grief. This festival, which was at first peculiar to this city, came afterwards to be observed throughout the empire; 742 miles S. of Peking. N. lat. $28^{\circ} 11'$. E. long. $112^{\circ} 25'$.

TCHANG-TCHEOU, a city of China, of the first rank, in Fo-kien; 950 miles S. of Peking. N. lat. $24^{\circ} 32'$. E. long. $117^{\circ} 34'$.—Also, a city of China, of the first rank, in Kiang-nan; 525 miles S.S.E. of Peking. N. lat. $31^{\circ} 50'$. E. long. $119^{\circ} 29'$.

TCHANG-TE, a city of China, of the first rank, in Hou-quang; 717 miles S.S.W. of Peking. N. lat. $29^{\circ} 2'$. E. long. $111^{\circ} 2'$.

TCHANG-YUEN, a town of Corea; 60 miles W.S.W. of Ho-ang-tcheou.—Also, a town of Corea; 30 miles S.E. of Kang-tcheou.

TCHANI, a lake of Russia, in the government of Kolivan, upwards of 200 miles in circumference; 100 miles W.N.W. of Kolivan.

TCHANKOUR, a town of Thibet; 105 miles S.E. of Sourman.

TCHAN-TE, a city of China, of the first rank, in Ho-nan. This is one of the most northern cities of the province. Two things are here remarkable: the first is a fish resembling a crocodile, the fat of which is of such a singular nature, that when once kindled it cannot be extinguished; the second is a mountain in the neighbourhood, so steep and inaccessible, that in time of war, it affords a place of refuge to the inhabitants, and a safe asylum from the insults and violence of the soldiery. Tchan-te contains in its district one city of the second class, and six of the third; 255 miles S.S.W. of Peking. N. lat. $36^{\circ} 6'$. E. long. 114° .

TCHAO-KING, a city of China, of the first rank, in Quang-tong, on the river Si; 1062 miles S.S.W. of Peking. N. lat. $23^{\circ} 3'$. E. long. $111^{\circ} 44'$.

TCHAO-NAIMAN-SOUMI-HOTUN, a town of Chinese Tartary; 198 miles N. of Peking. N. lat. $42^{\circ} 28'$. E. long. $115^{\circ} 44'$.

TCHAO-TCHEOU, a city of China, of the first rank, in Quang-tong, on the Pe-kiang; 1007 miles S. of Peking. N. lat. $23^{\circ} 37'$. E. long. $116^{\circ} 21'$.

TCHAOUTCHE-AGHISI, a town of Asiatic Turkey, in Natolia, on the Black sea; 12 miles N.W. of Erekli.

TCHAPIE-DSAKE-TOMPSOU, a lake of Thibet, about 54 miles in circumference. N. lat. $32^{\circ} 12'$. E. long. $84^{\circ} 34'$.

TCHARKAZ. See ZARCHAS.

TCHARONDA, a town of Russia, in the government of Novgorod, on the Sula; 188 miles E.N.E. of Novgorod. N. lat. $59^{\circ} 40'$. E. long. $37^{\circ} 34'$.

TCHASIRCONG, a town of Thibet, near the Ganges; 24 miles E. of Latac.

TCHASTIJA, an island of Russia, in the government of Irkutsk, on the Lena; 112 miles N.E. of Kirensk.

TCHAT, a mountain of Thibet, on the frontiers of Yarkan. N. lat. $33^{\circ} 10'$. E. long. $78^{\circ} 44'$.

TCHATELI, a town of Chinese Tartary, in the country of Hami; 38 miles N.W. of Hami-Hotun.

TCHAUNSKAIA, a gulf on the northern coast of Russia, in the Frozen sea. N. lat. 71° to 72° . E. long. 166° to 169° .

TCHAUSI, a town of Russia, in the government of Mogilev, on the Soz; 40 miles S.E. of Mogilev. N. lat. $53^{\circ} 36'$. E. long. $31^{\circ} 14'$.

TCHAZMIUNSKOI, a cape on the east coast of Kamtschatka; 52 miles S. of Verchni Kamtschatkoi. N. lat. $55^{\circ} 48'$. E. long. $160^{\circ} 15'$.

TCHERBAKSAR, a town of Russia, in the government of Kazan, on the Volga; 64 miles W.N.W. of Kazan. N. lat. $56^{\circ} 24'$. E. long. $46^{\circ} 30'$.

TCHERBARKULSKAIA, a fortress of Russia, in the government of Upha; 132 miles E. of Upha.

TCHECHUI, a river of Russia, which runs into the Lena, nearly opposite Ilnska.

TCHECO, a town of Thibet; 93 miles E.S.E. of Laffa.

TCHFTKAN, a town of Asiatic Turkey, in Adalia; 45 miles N.N.W. of Adana.

TCHEGEN, an island in the Caspian sea; 144 miles S. of Attrachan.

TCHEGOTCHINA, a river of Russia, which runs into the Kolima, N. lat. 68° . E. long. $150^{\circ} 14'$.

TCHEGUEDE HOTUN, a town of Chinese Tartary, on the east bank of the Amur, opposite Teldom; 673 miles N.N.E. of Peking. N. lat. $49^{\circ} 26'$. E. long. $127^{\circ} 37'$.

TCHEHARSHEBEH, a town of Asiatic Turkey, in Natolia; 30 miles S.E. of Alah Shehr.

TCHERKENAGUR, a town of Asiatic Turkey, in Caramania; 21 miles S. of Kirfhehr.

TCHÉ-KIANG, a province of China, bounded on the north and north-west by Kiang-nan, on the east by the sea, on the south by Fo-kien, and on the south-west by Kiang-fi; about 200 miles in length from north to south, and from 120 to 180 broad. This province, which was formerly the residence of some of the emperors, is one of the most considerable in the empire, on account of its maritime situation, extent, riches, and the number of its inhabitants. The air is pure and healthful; the plains are watered by a number of rivers and canals, kept in good order; and the springs and lakes, with which it abounds, contribute greatly to its fertility. The natives are mild and lively, and very polite to strangers; but they are said to be extremely superstitious. A prodigious quantity of silk-worms is bred in this province; whole plains may be seen covered with dwarf mulberry-trees, which are purposely checked in their growth: they are planted and pruned almost in the same manner as vines. Long experience has taught the Chinese, that the leaves of the smallest trees procure the best silks. The principal branch, therefore, of the trade of this province, consists in silk-stuffs; those in which gold and silver are intermixed are the most beautiful, and most esteemed in the empire. With regard to their common pieces, an immense quantity is sent to every part of China, to Japan, the Philippines, and to Europe;

Europe; and, notwithstanding this exportation, so much is left, that a complete fuit of silk may be bought here as cheap as one of the coarsest woollen-cloth in France. Excellent hams are brought from this province, and those small gold fish with which ponds are commonly stocked. The tallow-tree grows here, and a species of mushrooms, which are transported to every province of the empire. In Tchekiang there are reckoned to be 11 cities of the first class, 72 of the third, and 18 fortresses, which in Europe would be accounted large cities. (*Grozier's China*, vol. i. p. 64.) According to Sir George Staunton, the number of inhabitants amounts to 21 millions, and the province includes 39,150 square miles, or 25,056,000 acres. See CHINA.

TCHELAO, a town of Persia, in the province of Chorasan, or Khorassan: near it is a narrow defile in a mountain, called, by the orientalisks, Hell, from the difficulty of the passage.

TCHELBOSCH, a river of Russia, which joins the Bifuga, and runs with it into the sea of Azof; 40 miles S.W. of Eiskoi.

TCHELEH-DAGHI, a mountain of Natolia, N.E. of Boli.

TCHELGA, a town of Abyssinia; 20 miles N.W. of Gondar. N. lat. $12^{\circ} 44'$. E. long. $37^{\circ} 18'$.

TCHELIABINSK, a town of Russia, in the government of Upha; 188 miles E. of Upha. N. lat. $54^{\circ} 50'$. E. long. $62^{\circ} 4'$.

TCHELMINAR, or TCHILMINAR. See CHILMINAR. TCHEMURTAESKOI, in *Geography*, a fortress of Russia, in the government of Irkutsk; 60 miles S.W. of Selenginsk.

TCHEN, a town of Corea; 13 miles N.N.E. of Ping-hai.—Also, a city of China, of the second rank, in Ho-nan; 416 miles S.S.W. of Peking. N. lat. $34^{\circ} 46'$. E. long. $110^{\circ} 36'$.—Also, a city of China, of the second rank, in the island of Hai-nan; 57 miles S.W. of Kiong-tcheou. N. lat. $19^{\circ} 32'$. E. long. $108^{\circ} 49'$.

TCHEN-AN, a town of Corea; 35 miles S.S.E. of Hetfin.

TCHENBAR, a town of Russia, in the government of Penza; 80 miles W.S.W. of Penza. N. lat. $52^{\circ} 52'$. E. long. $43^{\circ} 30'$.

TCHENDEI, a river of Russia, which runs into the Yana, near its mouth.

TCHENE, a town of Egypt, on the right bank of the Nile; 18 miles N. of Enfeneh.

TCHENG-TCHANG, a town of Corea; 30 miles S.S.E. of Haimen.

TCHENG-TE, an island in the Eastern sea, near the south coast of Corea; about 10 miles long, and 6 broad. N. lat. $34^{\circ} 20'$. E. long. $128^{\circ} 37'$.

TCHEN-HAI, a town of Corea; 30 miles S. of Tfin-tcheou.

TCHENJEE. See HÆMUS.

TCHOU-CHAN, or CHU-SAN, an island in the Chinese sea, near the west coast of China, belonging to the province of Tchekiang, about 24 miles long, and from 4 to 10 broad.

TCHEPAGIRSKOI, a town of Russia, on the Podkamonskaia Tunguska. N. lat. $61^{\circ} 20'$. E. long. $96^{\circ} 44'$.

TCHPETKINA, a river of Russia, which runs into the Kolima, 88 miles N. of Verchnei Kovimskoi. N. lat. $67^{\circ} 35'$. E. long. $148^{\circ} 14'$.

TCHER, a river of Russia, which runs into the Don, near Tcherkovskaia, in the country of the Cossacks.

TCHERDAKLI, a town of Russia, in the government of Ekaterinoslav; 32 miles N. of Mariupol.

TCHEREDOVA, a town of Russia, in the government of Tobolsk, on the Irtisch; 16 miles N. of Tara.

TCHEREMISSES and TCHEUWASSES, tribes of people occupying the vicinity of the Volga, in the government of Regen. These people use the horse in their sacrifices, and chiefly white ones, especially in their great annual solemnities in autumn, of which none can partake, unless he has first bathed and put on a clean shirt.

TCHEREMSCHAN, a river of Russia, which runs into the Volga, near Singiliev, in the government of Simbirsk.

TCHEREPOVETZ, a town of Russia, in the government of Novgorod, on the Sula; 188 miles E.N.E. of Novgorod. N. lat. $59^{\circ} 40'$. E. long. $37^{\circ} 34'$.

TCHERGONA, *Valley of*, a sequestered beautiful valley of the Crimea, inhabited by the richest Tartars, who, from their vicinity to Aktiar, find a ready market for the produce of their lands; carrying thither honey, wax, fruit, and corn. This valley is described as the retreat of health and joy; the pipe and tabor sounding merrily among mountains, thick set with groves, which clothe them on every side. The performers consist of parties of Tzigankies, or gypsies, who, as mendicant artificers, musicians, and astrologers, are very common all over the south of Russia. They have also a wind-instrument resembling a haut-boy, made of the wood of cherry-tree, and they carry with them the large Tartar drum, characteristic of the Cimbric in the time of Strabo. These gypsies are much encouraged by the Tartars, who allow them to encamp among their villages and to exercise their various occupations. Many of them are rich, possessing fine horses and plenty of other cattle; but rich or poor, their mode of life is the same.

TCHERIKOV, a town of Russia, in the government of Mogilev, on the Soz; 80 miles S. of Mogilev. N. lat. $52^{\circ} 36'$. E. long. $30^{\circ} 54'$.

TCHERKASK, a town of Russia, in the country of the Cossacks, on the Don. The appearance of the town, viewed from the river, affords a most novel spectacle. Although not so grand as Venice, it somewhat resembles that city. The entrance to it is by broad canals, intersecting it in all parts. On each side, wooden houses, built on piles, appear to float upon the water: to these the inhabitants pass in boats, or by narrow bridges only two planks wide, with posts and rails, forming a causeway to every quarter of the town.

The town of Tcherkask is divided into eleven stanitzas, and contains 15,000 inhabitants, occupying about 3000 houses, and allowing, upon an average, five persons to each house. Here are seven churches, four built of stone and three of wood. One of these churches is appropriated to the Mahometan worship of the Tartars. The first erected in this place was founded by Peter the Great, and in this they keep what they call their regalia, applying the term to republican, rather than to regal, ensigns of distinction. Another church is built in the Grecian taste, with fourteen Corinthian columns, covered entirely with burnished gold. Almost all the other public edifices are constructed of wood. Here are six prisons, four for males and two for females; and the prisoners are allowed to go about begging in their chains. The shops are very numerous, kept chiefly by Greeks, and containing the produce of Turkey, as pearls, cloth, shawls, tobacco, fruit, &c. Here are two public baths, and each stanitza has its respective tavern. The inhabitants, according to Dr. Clarke in his *Travels* (vol. i.), are cleanly in their appearance, polished in their manners, well instructed, hospitable, generous, and disinterested, humane to the poor, good husbands, good brothers, good
wives,

wives, good mothers, virtuous daughters, valiant and dutiful sons. "A Cossack," he says, "placed by the side of a Russian, what a contrast!" 32 miles E.N.E. of Azof.

TCHERKASSES, or **TSCHERKASSIANS**, a tribe of people, who inhabit that part of Caucasus which is called the Great and Little Kabardia, the islands of the lower Kuban, and the southern bank of that river. (See **CIRCASSIA**.) These people are famous for their horses, which are about the size of the Kalmuck horse, ill-made, without elegance or proportion, and for the most part ewe-necked, but of such strong and hardy natures, as to be able to run five or six hundred English miles in three days.

TCHERKESH, a town of Asiatic Turkey, in Nattolia; 45 miles W.S.W. of Castamena.

TCHERKIN, a town of Abyssinia; 36 miles N. of Gondar. N. lat. $13^{\circ} 15'$. E. long. $37^{\circ} 40'$.

TCHERMAEVSKOI, a town of Russia, in the government of Tobolsk; 32 miles E.N.E. of Turinsk.

TCHERNAIA, a river of Russia, which runs into the Anadir, 100 miles below Anadirskoi.

TCHERNAIAGRIADA, a fortress of Russia, on the Volga; 32 miles N.N.W. of Astrachan.

TCHERNIGOV, a town of Russia, and capital of a government, on the Desna; 344 miles S.S.W. of Moscow. N. lat. $51^{\circ} 24'$. E. long. $31^{\circ} 14'$.

TCHERNIGOVSKOE, a government of Russia, bounded on the N. by Mogilevskoe, on the N.W. by Novgorod Sieverskoe, on the E. by Charkovskoe, on the S. by Kievskoe, and on the W. by Poland: about 180 miles long and 40 broad. N. lat. $49^{\circ} 50'$ to $51^{\circ} 5'$. E. long. 31° to 35° .

TCHERNIKEH, a town of Asiatic Turkey, in the government of Sivas, at the union of the Tosanlu and Jekil-Ermak; anciently a city of Pontus, and called Eupatoria, from Mithridates, surnamed Eupator; 24 miles N. of Amasia. N. lat. $40^{\circ} 26'$. E. long. $36^{\circ} 38'$.

TCHERNITZ. See **CZERNITZ**.

TCHERNOIYAR, a town of Russia, in the government of Saratov, defended by a ditch and chevaux-de-frieze, with some cannon; 200 miles N.W. of Astrachan. N. lat. $47^{\circ} 54'$. E. long. $46^{\circ} 4'$.

TCHERNOLUTZKAIA, a town of Russia, in the government of Tobolsk; 20 miles W. of Omsk.

TCHERNOMORSKI, or *Cossacks of the Black Sea*, a tribe of Cossacks, whose territory is separated by the river *Ae* or *Yea*, from that of the Grecian or Malo-Russian inhabitants, whose number does not exceed 700 persons, and the boundary of whose district is formed by the river *Ae* towards the S. and by the sea of Azof to the N. The Tchernomorski are a brave but rude and warlike people, and hospitable to strangers. Their original appellation was Zaporogtzi or Zaporagians, denoting their former situation "beyond the cataracts" of the Dnieper. From the banks of this river they were removed by the late empress Catharine to those of the Kuban, in order to repel the incursions of the Circassians and Tartars from the Turkish frontier. In consequence of the service they rendered to Russia in Catharine's last war with Turkey, the empress, by an ukase of the 2d of June, 1792, ceded to them the peninsula of Taman, and all the countries between the Kuban and the sea of Azof, as far as the rivers *Ae* and *Laba*; an extent of territory comprehending upwards of 1000 square miles. They had also a constitution allotted to them in all respects similar to that of the Don Cossacks, and received the appellation of "Cossacks of the Black sea." They were also allowed the privilege of choosing an Ataman; but their numbers have been considerably diminished. They could once

bring into the field an army of 40,000 effective cavalry; but at present, their number of troops does not exceed 15,000. They now occupy the whole country from the *Ae* to the Kuban, and from the Black sea to the frontier of the Don Cossacks. (See **COSSACKS**.) The Tchernomorski do not resemble the Cossacks of the Don in habits, disposition, or any other characteristic quality. The latter wear the true uniform; the former wear any habit according to their caprice. The Don Cossack is mild, affable, and polite; the Black-sea Cossack is blunt and even rude, from the boldness and martial hardihood of his manners. If he is poor, he appears clad like a primeval shepherd, or the wildest mountaineer; at the same time having his head bald, except one long braided lock from the crown, placed behind the right ear. This lock distinguishes the Tchernomorski Cossack from the Cossack of the Don, as well as from every other tribe of Cossacks in the Russian empire. If the Euxine Cossack is rich, he is very lavish in the costliness of his dress, which consists of embroidered velvet, and the richest silks and cloths of every variety of colour. The Tchernomorski are more cheerful and noisy than the Don Cossacks; turbulent in their mirth; vehement in conversation; somewhat querulous; and if not engaged in dispute, they are generally laughing or singing. Both these Cossacks hold one another in low estimation. The metropolis of the Tchernomorski Cossacks is "Ekaterinedara," or "Catherine's Gift." It has no resemblance to a town; but is rather a grove, or forest of oaks, in which a number of straggling cottages, widely separated, are concealed, not only from general observation, but from the view of each other. The country is covered with tumuli, which are very ancient, and appear by their remains to have been sepulchres. The government is wholly exercised by the Ataman and his officers, who wear theatrical and splendid habits. Their breasts are covered with chains of gold and gold-lace; their sabre is Turkish; their boots of red or yellow-coloured leather; their cap of black velvet, ornamented with lace and silver chains, or fine black Tartarian wool, taken from lambs in an embryo state. They bind their waist with silken sashes, sustaining pistols of the most costly workmanship. A small whip, with a short leather thong, is attached to their little finger. The lower extremity of their lance is supported by the right foot; and from the powder-flask, pendent in front, are suspended silver coins, and other trinkets. The Circassians and Tchernomorski carry on trade by a peculiar kind of barter. The exchange of corn, honey, mats, wood, and arms, for the salt of the Cossacks, is transacted without contract; the wares of the Circassians being placed on the ground where they find the salt ready stationed for barter. The Tchernomorski who are employed in guarding their cattle in the steppes, amounting to many thousands, from the depredations of the Circassians, pass the night upon the bare ground; and in order to protect themselves from the mosquitoes, which are both numerous and troublesome, creep into a kind of sack, sufficient only for the covering of a single person; beneath this they lie upon the thistles and other wild plants of the steppes. In order to avoid the excessive irritation and painful swelling occasioned by the stings of these ferocious insects, they light a number of fires to drive them from the cattle during the night; but their thirst of blood is so insatiate, that swarms will attack a person attempting to shelter himself even in the midst of smoke. See Clarke's Travels, vol. ii. 8vo.

TCHERNORIEGENSKAIA, a fortress of Russia, in the government of Upha, on the Ural; 12 miles W. of Orenburg.—**Alfo**, a fortress of Russia, in the government of Simbirsk, on the river Sak; 80 miles S.E. of Simbirsk.

TCHERPLINSKOI, a fortress of Russia, in the government of Upha, on the Ural; 124 miles E. of Orenburg.

TCHERTCHI, a town of Thibet; 20 miles S.W. of Harachar.

TCHERTOVSKA, a town of Russia, in the government of Irkutsk; 32 miles S.W. of Kirensk.

TCHERVLENA, a fortress of Russia, in the government of Caucasus, on the Malka; 64 miles E. of Ekaterinograd.

TCHESKAIA, a gulf or bay in the Frozen ocean, on the N. coast of Russia. N. lat. $66^{\circ} 50'$ to $77^{\circ} 40'$. E. long. 45° to 47° .

TCHESUCHINSKOI, a fortress of Russia, on the borders of China; 104 miles S.W. of Nertchinsk.

TCHE-TAN, a river of China, which runs into the Tom, 12 miles W. of Yeou.

TCHE-TCHEOU HOTUN, a town of Chinese Tartary, in the country of Hami; 983 miles E. of Peking. N. lat. $40^{\circ} 29'$. E. long. $94^{\circ} 21'$.

TCHETIRDAGH, a mountain of the Crimea, the *Trapezius* of Strabo, the height of which Pallas states to be about 1200 feet, and Dr. Clarke says, that it does not exceed 1300 feet; though the rapidity of its rise from the coast about Alufsta makes its elevation appear to be much greater. Almost the whole of the Crimea may be seen from its summit in clear weather. The higher parts of this mountain exhibit a mass of lime-stone, very compact and of a grey colour. Its ancient name, *Trapezius*, was probably derived from the table-form of its summit. The lower district is covered by groves impenetrable to the rays of the sun.

TCHEUISKOI, a town of Russia, in the government of Tobolsk, on the Oby; 48 miles N.N.E. of Kolivan.

TCH EVTZA, a river of Russia, which runs into the Viatka, near Slobodkoi, in the government of Viatka.

TCHIATAM, a town of Thibet; 510 miles E. of Lassa. N. lat. $28^{\circ} 3'$. E. long. $99^{\circ} 20'$.

TCHICOU, a town of Corea; 18 miles S.S.E. of Long Kouang.

TCHICSE, a town of Thibet; 12 miles E. of Latac.

TCHICTAMA, a town of Thibet; 15 miles N.E. of Pi-tchan.

TCHIEIN, a town of Russia, near the straits which separate the continent of Asia from America. N. lat. $65^{\circ} 40'$. E. long. $188^{\circ} 24'$.

TCHIGLING, a river of North America, which runs into the Frozen sea, opposite to the island of Chichitli.

TCHIKIRI, a river of Chinese Tartary, which runs into the Amur, 15 miles N. of Saghalien Oula Hotun.

TCHILINSKOI, a town of Russia, in the government of Irkutsk, on the Ingoda; 60 miles E. of Doroninsk.

TCHILLDIR MOUNTAINS, a name which is given to a very high ridge, formed by some branches of mount Caucasus, which taking an opposite direction of those known by the name of the "Mountains of Ceraunii," pass towards the S. and S.W., cross Ahgaz and Mingrelia, and encircle the Euxine to the E. and S.E. These unite in the above-named high ridge on the northern frontier of Immeretia, and again open into the Turkish province of Akisna. Here they assume the appellation of Tchildir, and would appear to separate into three branches, the most northern of which follows in a S.E. line the banks of the Cyrus, and ultimately produces an immense range, which running parallel with the Caspian, separates Irak from Ghilan and Mazanderan, and to the N. of Meshed is lost in the deserts of

Khorassan. In the neighbourhood of Sultanea and Caucween this range receives the name of Khai Caucasan, and in the vicinity of Tehraun it is called Elbourz. The middle ridge of the Tchildir mountains, under the denomination of the Mossian hills, traverses the province of Georgia, and bounds on the N. the delightful plain of Erivan. It then enters the Russian districts of the Karabaug and Karadaug, and gradually sinks into the plains of Mogan. The last and most southern branch of the Tchildir mountains, bending to the S. and E., passes the town of Kars, and forms a junction with mount Taurus. Kinneir's Mem. of the Persian Empire.

TCHINDAT TURUKUEVSKOI, a fort of Russia, in the government of Irkutsk; 72 miles S. of Nertchinsk.

TCHINDAT *Turukuevska*, a fortress of Russia, in the government of Irkutsk; 80 miles S.W. of Nertchinsk.

TCHINEH, a town of Asiatic Turkey, in Natolia; 15 miles W.N.W. of Moglah.

TCHING, a city of China, of the second rank, in Honan; 382 miles S. of Peking. N. lat. $33^{\circ} 49'$. E. long. $114^{\circ} 38'$.—Also, a city of China, of the second rank, in Honan; 340 miles S.S.W. of Peking. N. lat. $34^{\circ} 50'$. E. long. $113^{\circ} 29'$.

TCHI-NGAM, a city of China, of the second rank, in Se-tchuen; 780 miles S.W. of Peking. N. lat. $28^{\circ} 32'$. E. long. $107^{\circ} 4'$.

TCHING-CANG, a city of China, of the second rank, in Yun-nan; 1302 miles S.W. of Peking. N. lat. $24^{\circ} 12'$. E. long. $99^{\circ} 16'$.

TCHING-CHAN, a town of Corea; 30 miles S.S.E. of Ou-tchuen.

TCHING-HE, a town of Corea; 30 miles N.N.E. of Kang-tcheou.

TCHING-HIANG, a city of China, of the first rank, in Se-tchuen; 910 miles S.W. of Peking. N. lat. $27^{\circ} 18'$. E. long. $104^{\circ} 26'$.

TCHING-KIANG, a city of China, of the first rank, in Kiang-nan, on the south side of the river Yang-tse. This is not one of the largest cities of the province, for it is not above a league in circumference, and has authority over only three cities of the third class, but it is one of the most considerable for its situation and commerce; it is the key of the empire towards the sea, and is also a fortress, where there is also a strong garrison; the walls are above 30 feet in height in several places. The streets of the city and suburbs are paved with marble; 470 miles S.S.E. of Peking. N. lat. $32^{\circ} 14'$. E. long. $118^{\circ} 55'$.—Also, a city of China, of the first rank, in Yun-nan; 1082 miles S.S.W. of Peking. N. lat. $24^{\circ} 44'$. E. long. $102^{\circ} 40'$.

TCHING-NING, a city of China, of the second rank, in Koei-tcheou; 1017 miles S.S.W. of Peking. N. lat. $26^{\circ} 3'$. E. long. $105^{\circ} 23'$.

TCHING-TCHEOU, a city of China, of the first rank, in Hou-quang. This city is situated on an angle made by two rivers; the country is watered by a great number of brooks, which make the vallies exceeding fruitful; it is very full of mountains, which yield plenty of quick-silver, lapis lazuli, and green-stones for painting. There are also mines of silver and gold. The people who inhabit the mountains are not so polite as the rest of the Chinese; on the contrary, their rude and savage manners make them to be looked upon as barbarians. The district of this city contains one of the second order, and nine of the third; 765 miles S.S.W. of Peking. N. lat. $28^{\circ} 23'$. E. long. $109^{\circ} 40'$.—Also, a city of the province of Kiang-nan, situated near the canal through which all barks going from

Sou-tcheou to Kiang must pass. It is celebrated on account of its trade, and water which gives tea a pleasant taste: dependent on it are five cities of the third class, in which a particular kind of earthen-ware is manufactured, highly valued by the Chinese, and preferred to the most elegant porcelain.

TCHING-TEOU, a town of Corea; 30 miles S.S.W. of Kang-tcheou.

TCHING-TING, a city of China, of the first rank, in Pe-tche-li. Tching-ting is a large city, about four miles in circumference. Its jurisdiction is very extensive, and comprehends 32 towas; five of which are of the second, and 27 of the third class. Northward from it lie several mountains, where the Chinese say many simples and curious plants are to be found; on these mountains there are also several monuments or temples, erected in honour of deceased heroes; among which is one consecrated to the memory of the first emperor of the dynasty of Han; 137 miles S.S.W. of Peking. N. lat. $39^{\circ} 9'$. E. long. $114^{\circ} 20'$.

TCHING-TOU, a city of China, of the first rank, in Se-tchuen. This was formerly the residence of the emperors, and one of the largest and most beautiful cities in China; but in 1646, it was almost entirely destroyed, during the civil wars which preceded the last invasion by the Tartars. Its temples, bridges, and the ruins of ancient palaces, are objects of admiration to strangers; neither its commerce, nor the manners of its inhabitants, have any thing to distinguish it from other cities, nor its situation, which is, however, exceedingly pleasant. It has under its jurisdiction six cities of the second class and 25 of the third; 810 miles S.W. of Peking. N. lat. $30^{\circ} 40'$. E. long. $103^{\circ} 44'$.

TCHIN-HOÀ, a town of Corea; 50 miles E.N.E. of King-ki-tao.

TCHINKITANY BAY, a bay on the W. coast of North America, called by the Spaniards *Baya de Guadalupe*.

TCHIN-NAN, a city of China, of the second rank, in Yun-nan; 1187 miles S.W. of Peking. N. lat. $25^{\circ} 16'$. E. long. $101^{\circ} 4'$.

TCHIN-NGAN, a city of China, of the first rank, in Quang-fi; 1150 miles S.S.W. of Peking. N. lat. $23^{\circ} 21'$. E. long. 106° .

TCHIN-YUEN, a city of China, of the second rank, in Quang-fi; 1145 miles S.S.W. of Peking. N. lat. $23^{\circ} 14'$. E. long. $106^{\circ} 49'$.

TCHIRAKI, a town of Chinese Tartary, in the country of the Kalkas. N. lat. $48^{\circ} 36'$. E. long. $115^{\circ} 16'$.

TCHIRINKOUTAN, one of the small Kurile islands. N. lat. $49^{\circ} 20'$. E. long. $153^{\circ} 4'$.

TCHIRNOOI, one of the small Kurile islands. N. lat. $47^{\circ} 8'$. E. long. $151^{\circ} 50'$.

TCHIRON. See *SHIRON*.

TCHISEGI DAGHI, a mountain of Asiatic Turkey, in the government of Sivas, near Divriki.

TCHISTAY, a town of Bohemia, in the circle of Boleflau; 4 miles N.W. of Jung Buntzel.

TCHISTIAKOVA, a town of Russia, in the government of Perm; 36 miles N. of Perm.

TCHISTOKOLSK, a town of Russia, in the government of Kazan; 36 miles S.E. of Kazan. N. lat. $50^{\circ} 16'$. E. long. $49^{\circ} 54'$.

TCHI-TCHEOU, a city of China, of the first rank, in Kiang-nan; 570 miles S. of Peking. N. lat. $30^{\circ} 45'$. E. long. 117° .

TCHI-TCHOUAN, a town of Thibet; 20 miles N. of Chao-ma-ing Hotun.

TCHIUNA, a river of Russia, which rises six miles from Bratskoi, in the government of Kolivan, lat. 56° long. 101° , and runs into the Tunguska, 56 miles S.E. of Enifeisk. N. lat. $57^{\circ} 54'$. E. long. $93^{\circ} 34'$.

TCHIURAC, a river of Natolia, which runs into the Meinder near Tcheharthebeh.

TCHI-YUEN, a town of Corea; 15 miles S.E. of Tsin-tcheou.—Also, a city of China, of the first rank, in Koei-tcheou; 1000 miles S.S.W. of Peking. N. lat. $27^{\circ} 1'$. E. long. $107^{\circ} 51'$.

TCHO, a city of China, of the second rank, in Chan-fi, on the river Fuen; 298 miles S.W. of Peking. N. lat. $36^{\circ} 36'$. E. long. $111^{\circ} 23'$.

TCHOCO, a town of Thibet; 18 miles E. of Hara-char Hotun.

TCHOHA KIAMEN, a post of Chinese Tartary; 45 miles S.W. of Kara.

TCHOI. See *PALCATI Nor*.

TCHOKA. See *SAGHALIEN*.

TCHOL, a river of Chinese Tartary, which rises in lat. $48^{\circ} 20'$, long. $120^{\circ} 34'$, and runs into the Noupri, N. lat. $46^{\circ} 28'$. E. long. $123^{\circ} 31'$.

TCHOL Hotun, a town of Chinese Tartary, on a river of the same name; 500 miles N.N.E. of Peking. N. lat. $46^{\circ} 41'$. E. long. $123^{\circ} 35'$.

TCHOL-ABADI, a town of Asiatic Turkey, in Caramania; 32 miles S.W. of Aksehr.

TCHOM-COU-CHO, a town of Chinese Tartary; 25 miles S.W. of Ning-yuen.

TCHOM-YUEN, a town of Chinese Tartary; 15 miles N. of Geho.

TCHONG, a town of Corea; 68 miles from Kin-naitchan.—Also, a city of China, of the second rank, in Quang-fi; 1175 miles W. of Peking. N. lat. $22^{\circ} 26'$. E. long. $107^{\circ} 4'$.

TCHONG-HOTOC, a town of Thibet; 90 miles S.S.W. of Horatoubé.

TCHONG-KIANG-CHE, a town on the W. coast of Formosa. N. lat. $24^{\circ} 40'$. E. long. $138^{\circ} 2'$.

TCHONG-KING, a city of China, of the first rank, in Se-tchuen. This is one of the most commercial cities of the province. It is in a great measure indebted for its trade to its situation at the confluence of two remarkable rivers; one of which, called *Hin-cha-kiang*, or *Golden-sand*, receives in its course all the streams from the mountains, which rise on the neighbouring confines of Tartary. The other is *Ta-kiang*, which has its source beyond the boundaries of China, and is commonly called *Tang-tse-kiang*. Tchong-king is built upon a mountain, and rises in the form of an amphitheatre: the air round it is wholesome and temperate. This city is celebrated for its fish, and a particular kind of trunks, made with canes, interwoven in the manner of basket-work. It has in its district three cities of the second class, and eleven of the third; 750 miles S.W. of Peking. N. lat. $29^{\circ} 42'$. E. long. $106^{\circ} 19'$.

TCHONG-KOUE, or the *Middle Kingdom*, the name which the Chinese give to this empire; the western Moguls call it *Catay*; the Manchew Tartars, *Nican-courou*; the Japanese, *Thau*; and the people of Cochinchina and Siam, *Cin*, from which last appellation that of China is probably derived.

TCHONTORI, a town of Thibet; 175 miles S.E. of Hami. N. lat. $40^{\circ} 24'$. E. long. $96^{\circ} 34'$.

TCHORRO-TOHON-KIAMEN, a post of Chinese Tartary; 23 miles N. of Odoli.

TCHORS, a town of Persia, in the province of Adirbeitzan, inhabited by Curds, subject to Persia; 78 miles W.N.W. of Tauris.

TCHOSCHO, a small river of Russia, which runs into the Tcheskaia gulf, 40 miles N.N.E. of Mezen.

TCHOUCDOU, a town of Chinese Tartary; 20 miles N.N.W. of Petouné-Hotun.

TCHOUCHAN, a town of Corea; 38 miles S. of King-ki-tao.

TCHOUCHLOMA, a town of Russia, in the government of Kostrom; 76 miles N.E. of Kostrom. N. lat. $58^{\circ} 35'$. E. long. $42^{\circ} 40'$.

TCHOUCTEY-KIAMEN, a post of Chinese Tartary; 10 miles N.E. of Tchol.

TCHOUDSONG, a town of Thibet, on the borders of China; 340 miles S.E. of Laffa. N. lat. $27^{\circ} 22'$. E. long. $96^{\circ} 50'$.

TCHOUKIA-POURAN, a town of Thibet; 69 miles S.S.E. of Laffa.

TCHOU-KIONG, or **YUNG**, a city of China, of the first rank, in Yun-nan; 1187 miles S.W. of Peking. N. lat. $25^{\circ} 6'$. E. long. $101^{\circ} 20'$.

TCHOULGUE-HOTUN, a town of Chinese Tartary; 745 miles E.N.E. of Peking. N. lat. $44^{\circ} 1'$. E. long. $131^{\circ} 47'$.—Also, a town of Chinese Tartary; 840 miles E.N.E. of Peking. N. lat. $44^{\circ} 48'$. E. long. $133^{\circ} 49'$.

TCHOUMOU, a town of Thibet; 63 miles E.S.E. of Laffa.

TCHOUMOURTI, a town of Thibet, near the Ganges; 225 miles E.S.E. of Latac.

TCHOURHATAI, a town of Chinese Tartary. N. lat. $43^{\circ} 4'$. E. long. $119^{\circ} 45'$.

TCHOUSOR, a town of Thibet; 36 miles S.W. of Laffa.

TCHOU-TAN, a river of China, which runs into the Yuen, near Hong-kiang-fe.

TCHOU-TCHAN-TCHE, a town of the island of Formosa. N. lat. $24^{\circ} 48'$. E. long. $120^{\circ} 21'$.

TCHUDSKOI, a lake of Russia, between the governments of Petersburg and Riga; about 64 miles in length, and from 8 to 24 in breadth. N. lat. 58° to $59^{\circ} 10'$. E. long. 27° to $27^{\circ} 28'$. See **PEIPUS**.

TCHUGUEV, a town of Russia, in the government of Charkov; 12 miles E. of Charkov. N. lat. $49^{\circ} 58'$. E. long. $36^{\circ} 14'$.

TCHUKOTCH, a river of Russia, which runs into the Icy sea, N. lat. $71^{\circ} 30'$. E. long. $155^{\circ} 14'$.

TCHUKOTSKIJA, the most eastern province of Russia, in the government of Irkutsk, extending from N.W. to S.E., about 740 miles in length, and nearly 520 from N. to S. N. lat. 63° to $73^{\circ} 20'$. E. long. 157° to 159° .

TCHUKOTSKOI, a cape of the N.E. extremity of Siberia, at the entrance of the straits which divide the Pacific ocean from the Frozen sea, and the continent of America from Asia. N. lat. $66^{\circ} 15'$. E. long. $199^{\circ} 14'$.

TCHULIM, a river of Russia, formed by the union of several rivers, which runs into the Oby, near Moltchanovka.

TCHUMARA-STANITZ, a town of Russia, in the government of Irkutsk, on the Lena. N. lat. $61^{\circ} 12'$. E. long. $125^{\circ} 14'$.

TCHUMISCH, a river of Russia, which runs into the Oby, 6 miles S.S.E. of Koliwan.

TCHURKINO, a lake of Russia, 320 miles N.N.W. of Zashiverfk. N. lat. $72^{\circ} 30'$. E. long. $134^{\circ} 4'$.

TCHUSOVAIA, a town of Russia, in the government of Perm; 28 miles N. of Perm.—Also, a town of Russia,

in the government of Perm, at the union of the Tchusovaia and the Kama; 16 miles N. of Perm.—Also, a river of Russia, which joins the Silva, and runs into the Kama, about 12 miles above Perm.

TCHUSOVOI, a town of Russia, in the government of Perm; 40 miles N.E. of Perm.

TCHU-TCHEOU, a city of China, of the first rank, in Tche-kiang; 730 miles S.S.E. of Peking. N. lat. $28^{\circ} 36'$. E. long. $139^{\circ} 33'$.

TCI-NAN, or **TSI-NAN**, a city of China, of the first rank, in the province of Chan-tong, situated south of the river T'ing-ho, or Tfi: this city is large and populous, and is much respected by the Chinese, on account of its having been formerly the residence of a long series of kings, whose tombs, rising on the neighbouring mountains, afford a beautiful prospect. Tci-nan has under its jurisdiction four cities of the second class, and 26 of the third; 235 miles S. of Peking. N. lat. $36^{\circ} 46'$. E. long. $116^{\circ} 46'$.

TCIN-CHOU, a lake of China, about 37 miles in circumference; 25 miles N.N.E. of Tfin-tcheou.

TCING, a city of China, of the second rank, in Pe-tche-li; 130 miles S.S.W. of Peking. N. lat. $38^{\circ} 8'$. E. long. $114^{\circ} 6'$.

TCI-NGIN, a city of China, of the second rank, in Chang-tong; 275 miles S. of Peking. N. lat. $35^{\circ} 34'$. E. long. $116^{\circ} 24'$.

TCIN-TCHEOU, or **Tsin-tcheou**, a city of China, of the first rank, in Chang-tong. The principal branch of its commerce is fish, which are caught in such abundance, that, we are assured, the profit arising from their skins only is very considerable. It has in its district one city of the second class, and 13 of the third; 230 miles S.S.E. of Peking. N. lat. $36^{\circ} 46'$. E. long. $118^{\circ} 20'$.

TCITCICAR-HOTUN, a town of Chinese Tartary. This is the usual residence of a Tartarian general, and capital of a district. This city was built to guard the frontiers of the Chinese empire from the Russians. The city is fortified by close palisades, and a wall constructed of earth. The space inclosed by the former contains the tribunals and the house of the Tartar general; that which is between the palisades and the earthen wall is occupied by the soldiers of the Tartar garrison, merchants, and tradesmen, most of whom are Chinese invited hither by hopes of gain, or condemned to exile, and whose houses are only of earth, forming pretty large streets. The jurisdiction of the general who commands here extends over the new cities of Merguen and Saghalien-oula (city of the Black river): the latter being, on account of its situation, the most populous, the richest, and the most important. It is situated on the southern bank of the river Saghalien, commands a plain in which several villages have been built, and secures to the Mantchew Tartars the possession of extensive deserts covered with woods, in which a great number of fables are found.

The district to which this city belongs is the most northerly of the three departments of Eastern Chinese Tartary. It is occupied by different Tartar tribes, the principal of which are the Mantchews, Solons, and the Tagouris, the ancient inhabitants of the country. The two latter tribes submitted to the Mantchews, and implored their assistance against the Russians or Muscovites, who, with armed barks, passing from the Saghalien-oula into the Songari-oula, infested all the rivers which flow into them, and made themselves formidable to the Tartar nations who inhabited their banks. The Russians would soon have become masters of the valuable forests in which the fables are found, if the fort of Yafca, which they built on the river Saghalien, had been suffered to remain; but, by the treaty of peace concluded in 1689,

between the Russians and Chinese, it was agreed that it should be demolished, that no cause of umbrage or complaint might be left to the Tartar hunters.

The Tagouris, who appear to be the oldest inhabitants of the country, are tall, strong of body, and accustomed to labour; they build themselves houses, sow corn, and cultivate their lands, although they have always been surrounded by Tartars who live under tents, and are entirely ignorant of agriculture.

The Solon Tartars are still more robust, braver, and of greater ingenuity; they are almost all hunters; their women mount on horseback, handle the bow and the javelin, and follow in the chase stags and other wild animals. It is generally about the beginning of October that these Tartars depart to hunt fables, clad in a short close garment of wolf's skin: they cover their heads with a cap made of the same, and carry their bows suspended at their backs.

They take along with them several horses loaded with sacks of millet, and their long cloaks made of foxes' or tygers' skins, which they wrap round them to defend themselves from the cold, especially during the night. Their dogs are trained to this kind of hunting; they are accustomed to climb the steepest rocks, and know all the stratagems of the fables.

The fables' skins of this country are highly valued. Some of the rivers that run into the Saghalien-oula furnish pearls; 335 miles N.E. of Peking. N. lat. $47^{\circ} 25'$. E. long. $123^{\circ} 30'$.

TE, a city of China, of the second rank, in Chan-tong, on the grand canal; 150 miles S. of Peking. N. lat. $37^{\circ} 35'$. E. long. $115^{\circ} 50'$.

TEA-Tree, in *Botany*. See THEA.

TEA, in *common language*, denotes the leaves of the tea-tree, as they are imported into this country, and the infusion of them in boiling water. The term is more extensively applied to any other infusion of ordinary roots or herbs.

Dr. Lettson, in his botanical description of the tea-plant, thinks it most probable, that there is only one species, and that the difference between the green and bohea teas depends on the nature of the soil, culture, age, and the manner of drying the leaves. He adds, that it has even been observed, that a green tea-tree, planted in the bohea tea country, will produce bohea, and on the contrary; and that on his examining several hundred flowers, brought both from the bohea and green tea countries, their botanical characters have always appeared uniform. We are principally indebted to Kämpfer, Le Comte, and Du Halde, for an authentic history of the culture of this exotic shrub, and the manner of preparing or curing its leaves.

The particulars of greatest importance that have been recited, have lately been judiciously collected, and the subject further illustrated by additional observations by Dr. Lettson.

The tea-tree loves to grow in vallies, at the foot of mountains, and upon the banks of rivers, where it enjoys a southern exposure to the sun; though it endures considerable variations of heat and cold, as it flourishes in the northern climate of Peking, as well as about Canton; and it is observed that the degree of cold at Peking is as severe in winter as in some of the northern parts of Europe. However, the best tea grows in a mild temperate climate, the country about Nanking producing better tea than either Peking or Canton, betwixt which places it is situated.

The root resembles that of the peach-tree; the leaves are green, longish at the point, and pretty narrow, an inch and half long, and jagged all round. The flower is much like that of the wild rose, but smaller. The fruit is of different

forms, sometimes round, sometimes long, sometimes triangular, and of the ordinary size of a bean, containing two or three seeds, of a mouse-colour, including each a kernel. These are the seeds by which the plant is propagated: a number from six to twelve or fifteen being promiscuously put into one hole, four or five inches deep, at certain distances from each other. The seeds vegetate without any other care, though the more industrious annually remove the weeds, and manure the land. The leaves which succeed are not fit to be plucked before the third year's growth, at which period they are plentiful, and in their prime.

In about seven years the shrub rises to a man's height, and as it then bears few leaves, and grows slowly, it is cut down to the stem, which occasions an exuberance of fresh shoots and leaves the succeeding summer; some, indeed, defer cutting them till they are of ten years' growth. In Japan, the tea-tree is cultivated round the borders of the fields, without regard to the soil; but as the Chinese export considerable quantities of tea, they plant whole fields with it. The leaves are not collected from the cultivated plant till it is three years old; and after growing seven or ten years, it is cut down, in order that the numerous young shoots may afford a greater supply of leaves.

The best time to gather the leaves of tea is while they are yet small, young, and juicy; and the different periods in which they are gathered are particularly described by Kämpfer. The first gathering of the tea-leaves, according to this author, commences about the latter end of February, when the leaves are young and unexpanded. The second collection is made about the beginning of April, and the third in June. The first collection, which consists only of the fine tender leaves, is most esteemed, and is called Imperial tea. The second is called Tootsjaa, or Chinese tea, because it is infused and drunk after the Chinese manner. The last, which is the coarsest and cheapest, is chiefly consumed by the lower class of people. Besides the three kinds of tea here noticed, it may be observed, that by garbling or sorting these, the varieties of tea become still further multiplied. The leaves are plucked carefully one by one, and notwithstanding the seeming tediousness of this operation, the labourers are able to gather from four to ten or fifteen pounds each in one day. The tea-trees that yield often the finest leaves, grow on the steep declivities of hills, where it is dangerous, and in some cases impracticable to collect them. The Chinese are said to vanquish this difficulty by a singular contrivance. The large monies which inhabit these cliffs are irritated, and in revenge they break off the branches, and throw them down, so that the leaves are thus obtained. The leaves should be dried as soon as possible after they are gathered.

The buildings, or drying-houses, that are erected for curing of tea, contain from five to ten or twenty small furnaces, about three feet high, each having at the top a large flat iron pan. There is also a long low table covered with mats, on which the leaves are laid, and rolled by workmen, who sit round it: the iron pan being heated to a certain degree by a little fire made in the furnace underneath, a few pounds of the fresh-gathered leaves are put upon the pan; the fresh and juicy leaves crack when they touch the pan, and it is the business of the operator to shift them as quick as possible with his bare hands, till they become too hot to be easily endured. At this instant he takes off the leaves with a kind of shovel resembling a fan, and pours them on the mats before the rollers, who, taking small quantities at a time, roll them in the palm of their hands in one direction, while others are fanning them, that they may cool the more speedily, and retain their curl the longer. This process is repeated two or

three times, or oftener, before the tea is put into the stores, in order that all the moisture of the leaves may be thoroughly dissipated, and their curl more completely preserved. On every repetition the pan is less heated, and the operation performed more slowly and cautiously. The tea is then separated into the different kinds, and deposited in the store for domestic use or exportation.

The Chinese know nothing of *imperial tea*, *flower of tea*, and many other names, which in Europe serve to distinguish the goodness and the price of this fashionable commodity; but, beside the common tea, they distinguish two other kinds, *viz.* the *voui* and *soumo*, which are reserved for people of the first quality, and those who are sick. We have two principal kinds of tea in Europe; *viz.*

TEA, Green, which is the common tea of the Chinese, &c. F. le Comte calls it *bing* tea, and says it is gathered from the plant in April. It is held very digestive, and a little astringent; it gives a palish-green tincture to water, and its leaves are much twisted.

TEA, Bohea, which is the *voui* tea, or *bou tcha* of the Chinese. F. le Comte makes this only differ from the green tea, by its being gathered a month before it, *viz.* in March, while in the bud; and hence the smallness of the leaves, as well as the depth of the tincture it gives to water. Others take it for the tea of some particular province; the soil being found to make an alteration in the properties of the tea, as much as the season of gathering it. It is all bought at Nankin, and thence brought into Europe, where it is now much in vogue.

As to the differences in colour and flavour peculiar to these two kinds, and to their varieties, Dr. Lettsom thinks that there is reason to suspect that they are, in some measure, adventitious, or produced by art. He has been informed by intelligent persons, who have resided some time at Canton, that the tea about that city affords very little smell while growing. The same is observed of the tea-plants now in England, and also of the dried specimens from China. We are not, however, as he observes, to conclude from hence, that art alone conveys to tea, when cured, the smell peculiar to each kind; for our vegetable grasses, for instance, have little or no smell till they are dried and made into hay.

As to the opinion, that the green tea owes its verdure to an efflorescence acquired from the plates of copper on which it is supposed to be cured or dried, he shews that there is no foundation for this suspicion. The infusions of the finest imperial and bloom teas undergo no change on the affusion of a volatile alkali, which would detect the minutest portion of copper contained in them, by turning the liquors blue.

The fine green colour of these teas, with as little reason, hath been attributed to green copperas; as this metallic salt would, on its being dissolved in water, immediately act on the astringent matter of the leaves, and convert the infusion into ink, as happens when a chalybeate water has been employed in the making of tea.

On the whole, Dr. Lettsom thinks it not improbable, that some green dye prepared from vegetable substances, is employed in the colouring of the leaves of the green teas. And Neumann suspects, that the brown colour and the flavour of the bohea sorts are introduced by art. Both the green and bohea teas have an agreeable smell, and a lightly bitterish subastringent taste: with solution of chalybeate vitriol, they strike an inky blackness. They give out their smell and taste both to watery and spirituous menstrua; to water, the green sorts communicate their own green tincture, and the bohea, their brown; but to rectified spirit, they both impart a fine deep green. The extracts, obtained

by gently drawing off the menstrua from the filtered tinctures, are very considerably astringent, and not a little ungrateful; but the spirituous most so.

Savary also speaks of a sort of *red* tea, or *Tartar* tea, called *Honan tcha*, which tinges the water of a pale red, and which is said to be extremely digestive: by means of it the Tartars are said to be able to feed on raw flesh. Its taste is earthy, and much the least agreeable of them all: but this is scarcely known in England.

Tea is to be chosen of the briskest smell, and as whole as possible: and the greatest care is to be taken that it have not been exposed to the air to pall and evaporate.

The drink, tea, is made in China, and throughout the greatest part of the East, after the same manner as in Europe; *viz.* by infusing the leaves in boiling water, and drinking the infusion hot. Indeed, among us, it is usual to temper its bitterness with sugar, but the Orientals use it without the addition of sugar or milk.

However, the Japanese are said to prepare their liquor in a somewhat different way, *viz.* by pulverizing the leaves, stirring the powder in hot water, and drinking it as we do coffee.

From the account given by Du Halde, this method is not peculiar to the Japanese, but is also used in some provinces of China.

The common people, who have a coarser tea, boil it for some time in water, and make use of the liquor for common drink. Early in the morning, the kettle, filled with water, is regularly hung over the fire for this purpose, and the tea is either put into the kettle enclosed in a bag, or by means of a basket of proper size pressed to the bottom of the vessel, that there may be no hindrance in drawing off the water.

The Bantsjaa tea only is used in this manner, whose virtues, being more fixed, would not be so fully extracted by infusion.

The Chinese are always taking tea, especially at meals: it is the chief treat with which they regale their friends. The most moderate take it at least thrice a day; others ten times, or more; and yet it is computed, the consumption of tea among the English and Dutch is as great, in proportion, as among the Orientals.

With regard to the commercial history of tea, we may observe that it was first introduced into Europe by the Dutch East India Company, very early in the 17th century, and that a quantity of it was brought over from Holland by lord Arlington and lord Ossory, about the year 1666, at which time it was sold for 60s. a pound. But it appears, that before this time, drinking of tea, even in public coffee-houses in this country, was not uncommon; for in 1660, a duty of 8*d.* per gallon was laid on the liquor made and sold in all coffee-houses.

The present consumption of it is immense, both among the rich and poor. Dr. Lettsom tells us, that he has been informed, that at least three millions of pounds are allowed for the annual home consumption, not including the incredible quantity smuggled into the kingdom; and that the East India Company have generally in their warehouses a supply for three years.

In the appendix to sir George Staunton's Account of Lord Macartney's Embassy to China, we have several statements relating to the tea-trade with China. The average of teas exported from China to Europe in foreign ships, for nine years, *viz.* from March 1772 to 1780, the average of the number of ships being twelve, was 13,198,201 lbs.; in English ships, at the average of nine, 5,639,939 lbs.: the total average of ships is twenty-one, and of exported tea 18,838,140 lbs.

18,838,140 lbs. The annual consumption of tea by foreigners in Europe is estimated at 5,500,000 lbs.; and the consumption of Great Britain and her dependencies is at least 13,338,140 lbs., which, at 700,000 lbs. *per* ship, would employ thirty-eight large ships constantly in the China trade, instead of eighteen ships, as above, most of which were small, one fleet going out when another is coming home.

The above is exclusive of private trade teas, brought legally and illegally into Europe. It is said, upon the authority of confidential information, that the English ships have often smuggled from 1000 to 3000 chests of tea each; and also that the foreign captains bring a large quantity of tea, which they either smuggle at sea, or throw into the sea, the punishment being severe. The loss to the public on 1000 chests of hyson tea smuggled, is above 20,000*l*.

The average quantities for one year of each sort of tea sold by the East India Company in ten years, from March sale 1773 to September sale 1782 inclusive, exclusive of private trade, which was trifling, are as follow :

Bohea - - -	3,075,307 lbs.
Congou - - -	523,272
Souchong and Pekoe	92,572
Singlo - - -	1,832,474
Hyson - - -	218,839
	<hr/>
	5,742,464

See COMMUTATION *AA*.

As to the properties of tea, they are strangely controverted: the Eastern nations are at least as much possessed with an idea of their extraordinary virtues as the Europeans; but it is, perhaps, because imagination bears as great a sway there as here. The reason why the gout and stone are unknown in China, is ascribed to the use of this plant.

Tea is extolled as the greatest of all medicines: moderately and properly taken, it acts as a gentle astringent and corroborative: it strengthens the stomach and bowels, and is good against nauſeas, indigestions, and diarrhœas. It acts also as a diuretic and diaphoretic. The immoderate use of it, however, has been very prejudicial to many, who have been thereby thrown into the diabetes.

And also in Europe, infusions of tea-leaves have been extravagantly condemned by some, and commended by others. From the contradictory opinions, even of medical writers, on this subject, the natural inference seems to be, that they possess neither noxious nor beneficial powers, in any very considerable degree. They seem, when moderately used, to be for the most part innocent; in some cases they seem to be salutary; in some they are apparently prejudicial. They dilute thick juices, and quench thirst more apparently, and pass off by the natural emunctories more freely, than more watery fluids: they refresh the spirits in heaviness and sleepiness, and seem to counteract the operation of inebriating liquors.

From their manifest astringency, they have been supposed to strengthen and brace up the solids, but this effect experience does not countenance; as it is in disorders, and in constitutions in which corroborants are more serviceable, that the immoderate use of tea is peculiarly hurtful; in cold indolent habits, cachexies, chlorosis, dropies, and debilities of the nervous system. Lewis's *Mat. Med.*

Dr. Lettſom has particularly inquired into the medical qualities and effects of tea; and having observed that infusions of bohea and green tea contribute to preserve sweet some small pieces of beef immersed in them, he infers that they possess an antiseptic power, when applied to the dead

animal fibre, and from their striking a purple colour with salt of iron, he deduces their astringent quality.

From other experiments he concludes, that the activity of tea chiefly resides in its fragrant and volatile parts; and that if the use of it be beneficial or injurious to any particular constitution, it becomes so principally by means of this odorous fragrant principle. He apprehends that it is the safest course to use the infusion of the more ordinary kinds of this plant, which abound less with this fragrant principle. Or the tea may be boiled a few minutes, in order to dissipate this volatile part, which stands charged as the cause of those nervous affections that are said to be produced, or aggravated, by the use of this liquor. By this process may likewise be extracted more copiously the more fixed, bitter, and stomatic parts of this vegetable.

Dr. Lettſom, who seems to be thoroughly persuaded of the occasionally noxious effects of this volatile principle, in the finer teas especially, recommends this last mentioned mode of making tea, or the substitution of the extract instead of the leaves; by the use of which the nervous relaxing effects, which follow the drinking of tea in the usual manner, would be in great measure avoided. This extract has been imported hither from China, in the form of small cakes, not exceeding a quarter of an ounce each in weight, ten grains of which might suffice one person for breakfast; but it might easily be made here by simple decoction and evaporation, by those who experience the noxious qualities of the volatile principles of this plant.

It may be farther observed, that the effect of drinking large quantities of any warm aqueous liquor would be to enter speedily into the course of circulation, and pass off as speedily by urine or perspiration, or the increase of some of the secretions.

Its effects on the solid parts of the constitution would be relaxing, and thereby enfeebling.

If this warm aqueous fluid were taken in considerable quantities, its effects would be proportionable, and still greater if it were substituted instead of nutriment. The infusion of tea, however, has these two peculiarities. It is not only possessed of a sedative quality, but also of a considerable astringency; by which the relaxing power, ascribed to a mere aqueous fluid, is in some measure corrected on this account. It is, perhaps, less injurious than many other infusions of herbs, which, besides a very slight aromatic flavour, have very little, if any, stypticity, to prevent their relaxing debilitating effects.

So far, therefore, tea, if not too fine, if not drank too hot, nor in too great quantities, is perhaps preferable to any other known vegetable infusion. And if we take into consideration, likewise, its known enlivening energy, our attachment to it will appear to be owing to its superiority in taste and effects to most other vegetables. See Dr. Lettſom's *Natural History of the Tea-tree, with Observations on the Medical Qualities of Tea, and Effects of Tea-drinking*, 4to. 1772.

Tea may be considered as a very powerful aphrodisiac; and accordingly, a physician of considerable eminence in his profession, imputes the amazing population of China, amongst other causes, to the general use of it. Percival's *Ess.* p. 63.

We shall close this part of the article with a transcript of its medicinal powers, as they are stated by Dr. Cullen (*Mat. Med.* vol. ii.) "With respect to its qualities as a medicine, that is, its power of changing the state of the human body, we might suppose it ascertained by the experience of its daily use; but from the universality of this use in very different conditions of the plant, and in every possible condition of

the persons employing it, the conclusions drawn from its effects must be very precarious and ambiguous, and we must attempt by other means to ascertain its qualities with more certainty.

“ To this purpose it appears, from the accurate Dr. Smith's experiments ‘ De Actione Musculari,’ No. 36, that an infusion of green tea has the effect of destroying the sensibility of the nerves, and the irritability of the muscles; and from the experiments of Dr. Lettfoam, it appears that green tea gives out in distillation an odorous water, which is powerfully narcotic.

That the recent plant contains such an odorous narcotic power, we might presume from the necessity which the Chinese find of drying it with much heat before it can be brought into use; and that, even after such preparation, they must abstain from the use of it for a year or more, that is, till its volatile parts are still farther dissipated: and it is said, that unless they use this precaution, the tea in a more recent state manifestly shews strong narcotic powers. Even in this country, the more odorous teas often shew their sedative powers in weakening the nerves of the stomach, and indeed of the whole system.

“ From these considerations we conclude very firmly, that tea is to be considered as a narcotic and sedative substance; and that it is especially such in its most odorous state, and therefore less in the bohea than in the green tea, and the most so in the more odorous, or what are called the finer kinds of the latter.

“ Its effects, however, seem to be very different in different persons; and hence the different, and even contradictory accounts that are reported of these effects. But if we consider the difference of constitution, which occasions some difference of the operation of the same medicine in different persons, and of which we have a remarkable proof in the operation of opium, we shall not be surpris'd at the different operations of tea.

“ If to this we add the fallacy arising from the condition of the tea employed, which is often so inert as to have no effects at all; and if we still add to this the power of habit, which can destroy the powers of the most powerful substances, we shall not allow the various and even contradictory reports of its effects to alter our judgment, with respect to its ordinary and more general qualities in affecting the human body.

“ From the experiments above-mentioned, and from the observations which I have made in the course of fifty years, in all sorts of persons, I am convinced that the qualities of tea are narcotic and sedative.

“ It has been often alleged, that some of the bad effects imputed to tea are truly owing to the large quantity of warm water which commonly accompanies it, and it is possible that some bad effects may arise from this cause: but from attentive observation I can assert, that wherever any considerable effects appear, they are in nine of every ten persons entirely from the qualities of the tea; and that any like effects of warm water do not appear in one of a hundred who take in this very largely.

“ But while we thus endeavour to establish the poisonous nature of tea, we do not at the same time deny that it may sometimes shew useful qualities. It is very possible, that in certain persons, taken in moderate quantity, it may, like other narcotics in a moderate dose, prove exhilarating, or, like these, have some effect in taking off irritability, or in quieting some irregularities of the nervous system.

“ As its bad effects have been often imputed to the warm water that accompanies it, so we have no doubt that some of its good effects may also be ascribed to the same cause,

and particularly its being so often grateful after a full meal.”

By 9 Geo. II. c. 35, if a vessel, coming from foreign parts, and having 6 lbs. or more of tea on board, shall be found at anchor, or within two leagues of the shore, &c. all such tea, with chest and package, shall be forfeited. The importer of any coffee, tea, or cocoa-nuts, shall within thirty days enter the said tea, &c. and warehouse it. (10 Geo. c. 10. 5 Geo. III. c. 43.) That which is landed without entry and warehousing shall be forfeited. But this shall not extend to any coffee or tea imported by the East India Company. The coffee and tea intended for home consumption shall be entered and the duty paid. (10 G. c. 10.) A permit shall be given for the removal of tea from any warehouse, whether it be bohea, congou, fouchong, or pekoe tea; and such tea shall in the permit be specified under the denomination of *black* tea; and if the tea be neither bohea, congou, fouchong, nor pekoe tea, then such tea shall be specified under the denomination of *green* tea. 43 Geo. III. c. 129.

By 13 Geo. III. c. 44. no licence shall be granted to the East India Company to export tea, unless there remain in the warehouses a quantity not less than ten millions of pounds weight.

No tea is allowed to be imported, except from the place of its growth, on pain of forfeiture. (11 Geo. c. 30.) And by 24 Geo. III. c. 38. all the duties upon tea imported, sold, or used in this kingdom, shall cease from September 15, 1784; at which period the East India Company is discharged from the payment of duties on tea in their warehouses; and afterwards there shall be paid a duty of 12l. 10s. *per cent.* computed upon the gross prices for all tea delivered by the Company to the purchasers, which duty shall be drawn back on exportation to any place where the drawback is already allowed. The Company is required to make four sales in the year, and to sell such quantity as shall be sufficient to supply the demand, provided an advance of 1d. *per lb.* be bid upon the prices at which the teas shall be put up; and at the four first sales after passing the act, these prices shall not exceed the following rates; *viz.* for bohea tea, 1s. 7d. *per lb.*; congou tea, 2s. 5d. *per lb.*; for fouchong tea, 3s. 3d. *per lb.*; for singlo tea, 3s. 4d. *per lb.*; and for hyson tea, 4s. 11d. *per lb.*: and afterwards the whole price at which the teas are put up, shall not exceed the prime cost, with the freight and charges of importation, lawful interest from the time of the arrival of such tea in Great Britain, and the common premium of insurance. In lieu of the duties on tea, this act substitutes an additional duty on windows. See *COMMUTATION AA.*

By this same act, the inland duty upon cocoa-nuts and coffee shall cease from September 15, 1784, and the following additional duties be paid; *viz.* for every pound of cocoa-nuts, the produce of British America, 6d. and the produce of any other place, 1s. 6d.; and for every pound of coffee, the produce of British America, 6d. and the produce of any other place, 2s. 6d.; and these duties are subject to an additional impost of 5 *per cent.* and 5 *per cent.* thereon imposed by 19 Geo. III. c. 25. and 22 Geo. III. c. 66.

If coffee or tea are intended to be taken out for exportation, they shall be delivered out on security that they shall be exported, and not reloaded. 13 Geo. c. 10.

No drawback shall be allowed on tea exported, except to Ireland, &c. where the whole duty on exportation shall be allowed. 18 Geo. II. c. 26. 17 Geo. III. c. 27. 43 Geo. III. c. 69.

Every person having in his custody more than six pounds weight of tea, is a dealer; and selling without a licence, to

18,838,140 lbs. The annual consumption of tea by foreigners in Europe is estimated at 5,500,000 lbs.; and the consumption of Great Britain and her dependencies is at least 13,338,140 lbs., which, at 700,000 lbs. *per* ship, would employ thirty-eight large ships constantly in the China trade, instead of eighteen ships, as above, most of which were small, one fleet going out when another is coming home.

The above is exclusive of private trade teas, brought legally and illegally into Europe. It is said, upon the authority of confidential information, that the English ships have often smuggled from 1000 to 3000 chests of tea each; and also that the foreign captains bring a large quantity of tea, which they either smuggle at sea, or throw into the sea, the punishment being severe. The loss to the public on 1000 chests of hyson tea smuggled, is above 20,000*l*.

The average quantities for one year of each sort of tea sold by the East India Company in ten years, from March sale 1773 to September sale 1782 inclusive, exclusive of private trade, which was trifling, are as follow :

Bohea - - -	3,075,307 lbs.
Congou - - -	523,272
Souchong and Pekoe	92,572
Singlo - - -	1,832,474
Hyson - - -	218,839

They seem, when moderately used, to be for the most part innocent; in some cases they seem to be salutary; in some they are apparently prejudicial. They dilute thick juices, and quench thirst more apparently, and pass off by the natural excretories more freely, than more watery fluids: they refresh the spirits in heaviness and sleepiness, and seem to counteract the operation of inebriating liquors.

From their manifest astringency, they have been supposed to strengthen and brace up the solids, but this effect experience does not countenance; as it is in disorders, and in constitutions in which corroborants are more serviceable, that the immoderate use of tea is peculiarly hurtful; in cold indolent habits, cachexies, chlorosis, dropics, and debilities of the nervous system. Lewis's *Mat. Med.*

Dr. Lettſom has particularly inquired into the medical qualities and effects of tea; and having observed that infusions of bohea and green tea contribute to preserve sweet some small pieces of beef immersed in them, he infers that they possess an antiseptic power, when applied to the dead

animal fibre, and from their striking a purple colour with salt of iron, he deduces their astringent quality.

From other experiments he concludes, that the activity of tea chiefly resides in its fragrant and volatile parts; and that if the use of it be beneficial or injurious to any particular constitution, it becomes so principally by means of this odorous fragrant principle. He apprehends that it is the safest course to use the infusion of the more ordinary kinds of this plant, which abound less with this fragrant principle. Or the tea may be boiled a few minutes, in order to dissipate this volatile part, which stands charged as the cause of those nervous affections that are said to be produced, or aggravated, by the use of this liquor. By this process may likewise be extracted more copiously the more fixed, bitter, and stomachic parts of this vegetable.

Dr. Lettſom, who seems to be thoroughly persuaded of the occasionally noxious effects of this volatile principle, in the finer teas especially, recommends this last mentioned mode of making tea, or the substitution of the extract instead of the leaves; by the use of which the nervous relaxing effects, which follow the drinking of tea in the usual manner, would be in great measure avoided. This extract has been imported hither from China, in the form of small cakes, not exceeding a quarter of an ounce each in weight, ten grains of which might suffice one person for breakfast; but it might easily be made here by simple decoction and evaporation, by those who experience the noxious qualities of the volatile principles of this plant.

It may be farther observed, that the effect of drinking large quantities of any warm aqueous liquor would be to enter speedily into the course of circulation, and pass off as speedily by urine or perspiration, or the increase of some of the secretions.

Its effects on the solid parts of the constitution would be relaxing, and thereby enfeebling.

If this warm aqueous fluid were taken in considerable quantities, its effects would be proportionable, and still greater if it were substituted instead of nutriment. The infusion of tea, however, has these two peculiarities. It is not only possessed of a sedative quality, but also of a considerable astringency; by which the relaxing power, ascribed to a mere aqueous fluid, is in some measure corrected on this account. It is, perhaps, less injurious than many other infusions of herbs, which, besides a very slight aromatic flavour, have very little, if any, stypticity, to prevent their relaxing debilitating effects.

So far, therefore, tea, if not too fine, if not drank too hot, nor in too great quantities, is perhaps preferable to any other known vegetable infusion. And if we take into consideration, likewise, its known enlivening energy, our attachment to it will appear to be owing to its superiority in taste and effects to most other vegetables. See Dr. Lettſom's *Natural History of the Tea-tree, with Observations on the Medical Qualities of Tea, and Effects of Tea-drinking*, 4to. 1772.

Tea may be considered as a very powerful aphrodisiac; and accordingly, a physician of considerable eminence in his profession, imputes the amazing population of China, amongst other causes, to the general use of it. Percival's *Ess.* p. 63.

We shall close this part of the article with a transcript of its medicinal powers, as they are stated by Dr. Cullen (*Mat. Med.* vol. ii.) "With respect to its qualities as a medicine, that is, its power of changing the state of the human body, we might suppose it ascertained by the experience of its daily use; but from the universality of this use in very different conditions of the plant, and in every possible condition of

the persons employing it, the conclusions drawn from its effects must be very precarious and ambiguous, and we must attempt by other means to ascertain its qualities with more certainty.

“ To this purpose it appears, from the accurate Dr. Smith’s experiments ‘ De Actione Musculari,’ No. 36, that an infusion of green tea has the effect of destroying the sensibility of the nerves, and the irritability of the muscles; and from the experiments of Dr. Lettfoam, it appears that green tea gives out in distillation an odorous water, which is powerfully narcotic.

That the recent plant contains such an odorous narcotic power, we might presume from the necessity which the Chinese find of drying it with much heat before it can be brought into use; and that, even after such preparation, they must abstain from the use of it for a year or more, that is, till its volatile parts are still farther dissipated: and it is said, that unless they use this precaution, the tea in a more recent state manifestly shews strong narcotic powers. Even in this country, the more odorous teas often shew their sedative powers in weakening the nerves of the stomach, and indeed of the whole system.

“ From these considerations we conclude very firmly, that tea is to be considered as a narcotic and sedative substance; and that it is especially such in its most odorous state, and therefore less in the bohea than in the green tea, and the most so in the more odorous, or what are called the finer kinds of the latter.

“ Its effects, however, seem to be very different in different persons; and hence the different, and even contradictory accounts that are reported of these effects. But if we consider the difference of constitution, which occasions some difference of the operation of the same medicine in different persons, and of which we have a remarkable proof in the operation of opium, we shall not be surpris’d at the different operations of tea.

“ If to this we add the fallacy arising from the condition of the tea employed, which is often so inert as to have no effects at all; and if we still add to this the power of habit, which can destroy the powers of the most powerful substances, we shall not allow the various and even contradictory reports of its effects to alter our judgment, with respect to its ordinary and more general qualities in affecting the human body.

“ From the experiments above-mentioned, and from the observations which I have made in the course of fifty years, in all sorts of persons, I am convinced that the qualities of tea are narcotic and sedative.

“ It has been often alleged, that some of the bad effects imputed to tea are truly owing to the large quantity of warm water which commonly accompanies it, and it is possible that some bad effects may arise from this cause: but from attentive observation I can assert, that wherever any considerable effects appear, they are in nine of every ten persons entirely from the qualities of the tea; and that any like effects of warm water do not appear in one of a hundred who take in this very largely.

“ But while we thus endeavour to establish the poisonous nature of tea, we do not at the same time deny that it may sometimes shew useful qualities. It is very possible, that in certain persons, taken in moderate quantity, it may, like other narcotics in a moderate dose, prove exhilarating, or, like these, have some effect in taking off irritability, or in quieting some irregularities of the nervous system.

“ As its bad effects have been often imputed to the warm water that accompanies it, so we have no doubt that some of its good effects may also be ascribed to the same cause,

and particularly its being so often grateful after a full meal.”

By 9 Geo. II. c. 35, if a vessel, coming from foreign parts, and having 6 lbs. or more of tea on board, shall be found at anchor, or within two leagues of the shore, &c. all such tea, with chest and package, shall be forfeited. The importer of any coffee, tea, or cocoa-nuts, shall within thirty days enter the said tea, &c. and warehouse it. (10 Geo. c. 10. 5 Geo. III. c. 43.) That which is landed without entry and warehousing shall be forfeited. But this shall not extend to any coffee or tea imported by the East India Company. The coffee and tea intended for home consumption shall be entered and the duty paid. (10 G. c. 10.) A permit shall be given for the removal of tea from any warehouse, whether it be bohea, congou, fouchong, or pekoe tea; and such tea shall in the permit be specified under the denomination of *black* tea; and if the tea be neither bohea, congou, fouchong, nor pekoe tea, then such tea shall be specified under the denomination of *green* tea. 43 Geo. III. c. 129.

By 13 Geo. III. c. 44. no licence shall be granted to the East India Company to export tea, unless there remain in the warehouses a quantity not less than ten millions of pounds weight.

No tea is allowed to be imported, except from the place of its growth, on pain of forfeiture. (11 Geo. c. 30.) And by 24 Geo. III. c. 38. all the duties upon tea imported, sold, or used in this kingdom, shall cease from September 15, 1784; at which period the East India Company is discharged from the payment of duties on tea in their warehouses; and afterwards there shall be paid a duty of 12*l.* 10*s.* per cent. computed upon the gross prices for all tea delivered by the Company to the purchasers, which duty shall be drawn back on exportation to any place where the drawback is already allowed. The Company is required to make four sales in the year, and to sell such quantity as shall be sufficient to supply the demand, provided an advance of 1*d.* per lb. be bid upon the prices at which the teas shall be put up; and at the four first sales after passing the act, these prices shall not exceed the following rates; viz. for bohea tea, 1*s.* 7*d.* per lb.; congou tea, 2*s.* 5*d.* per lb.; for fouchong tea, 3*s.* 3*d.* per lb.; for singlo tea, 3*s.* 4*d.* per lb.; and for hyson tea, 4*s.* 11*d.* per lb.: and afterwards the whole price at which the teas are put up, shall not exceed the prime cost, with the freight and charges of importation, lawful interest from the time of the arrival of such tea in Great Britain, and the common premium of insurance. In lieu of the duties on tea, this act substitutes an additional duty on windows. See COMMUTATION *Act*.

By this same act, the inland duty upon cocoa-nuts and coffee shall cease from September 15, 1784, and the following additional duties be paid; viz. for every pound of cocoa-nuts, the produce of British America, 6*d.* and the produce of any other place, 1*s.* 6*d.*; and for every pound of coffee, the produce of British America, 6*d.* and the produce of any other place, 2*s.* 6*d.*; and these duties are subject to an additional impost of 5 per cent. and 5 per cent. thereon imposed by 19 Geo. III. c. 25. and 22 Geo. III. c. 66.

If coffee or tea are intended to be taken out for exportation, they shall be delivered out on security that they shall be exported, and not re-landed. 13 Geo. c. 10.

No drawback shall be allowed on tea exported, except to Ireland, &c. where the whole duty on exportation shall be allowed. 18 Geo. II. c. 26. 17 Geo. III. c. 27. 43 Geo. III. c. 69.

Every person having in his custody more than six pounds weight of tea, is a dealer; and selling without a licence, to

be had for 12*d.*, shall forfeit 5*l.* a month. (11 Geo. c. 30.) If any person offer any tea to sale without a permit, or a pedlar with one, the person to whom it is offered may seize the same, &c. 9 Geo. II. c. 35. See COFFEE.

Every person dealing in tea, &c. shall cause to be painted or written over the door of his shop, the words *dealer in coffee, tea, cocoa-nuts, or chocolate*, on pain of 20*l.* (19 Geo. III. c. 69.) And any dealer buying of any person who has not this inscription, incurs forfeiture of 100*l.*, and any other person 10*l.* By 20 Geo. III. c. 35. no person shall trade in coffee, tea, or chocolate, without a licence, at the price (by 43 Geo. III. c. 69.) of 5*s.* 6*d.*, under penalty of 20*l.* The adulteration of tea is subject to a penalty of 100*l.* besides the forfeiture of the same, and for every pound of dyed leaves of tea, 5*l.* 11 Geo. c. 30. 17 Geo. III. c. 29.

At the East India Company's sale of teas, an account shall be taken of the buyers and prices, and the best bidder shall within three days deposit with the Company, or their clerks, 40*s.* for every tub or chest of tea, on pain of six times the value, and such sale shall be void, and the same shall in 14 days after be put up again. (18 Geo. II. c. 26.) And by 13 Geo. III. c. 44. the deposit for every tub and chest of bohea tea shall be 4*l.* By 13 Geo. III. c. 44. tea may be exported. No tea shall be received, with or without a permit, within the limits of the bills of mortality; and no tea, exceeding 20*lbs.* weight, shall at one time be received, with or without a permit, out of the said limits, on pain of forfeiture. (21 Geo. III. c. 55. 22 Geo. III. c. 68. 23 Geo. III. c. 70.) All tea seized and condemned shall be sold to the best bidder. (24 Geo. III. sess. 2. c. 47.) Tea carried in the night, with or without a permit, except in certain circumstances, shall be forfeited, and may be seized by any officer for the inland duties as tea. 21 Geo. III. c. 55.

TEA, *Buckthorn*. See RHAMNUS.

TEA, *German*. See SPEEDWELL.

TEA, *Mexico*, *Chenopodium ambrosioides* of Linnæus, is a species of chenopodium, which, as well as the Jerusalem oak, or chenopodium botrys, are natives of the southern parts of Europe, and sown annually with us in gardens. Infusions of the leaves and flowery heads of both these plants, which are not unpalatable, drank as tea, are said to be of service in humoral asthmas and coughs, and other disorders of the breast; they are supposed to be antispasmodic and antihysterical. Lewis's Mat. Med.

TEA, *New Jersey*. See CEANOTHUS.

TEA, *New Zealand*. See PHILADELPHUS.

TEA, *Oswego*. See MONARDA.

TEA, *Paraguay, or South Sea*. See PARAGUAY.

TEA, *West Indian*. See SIDA.

TEA Soup, in *Rural Economy*, that which is prepared from the tea, liquid, or infusion of some sort of vegetable substance or other, such as hay, cut straw, or haulm, &c. by thickening it a little with some sort of mealy material, or mashed potatoes, or other such roots, after being boiled or steamed.

TEA, in *Geography*, a river of England, in the county of Buckingham, which runs into the Ouse near Stony Stratford.

TEAHOWRAY. See PORTLAND Island.

TEAK, or TEEK, a species of timber that occurs frequently in various parts of the East Indies, and which is applied to a variety of domestic and nautical purposes. Extensive forests of these trees border on the banks of the Godavery within the mountains, and supply abundance of ship-timber for the adjacent ports. The teak forests, from which the marine yard at Bombay is furnished with that ex-

cellent species of ship-timber, lie along the western side of the Gout mountains, and other contiguous ridges of hills, as the N. and N.E. of Basseen; the numerous rivulets that descend from them affording water-carriage for the timber. Major Rennell reproaches the unpardonable negligence with which Europeans are chargeable for delaying to build ships of war for the service of the Indian seas. They might be freighted home, without the ceremony of regular equipment, as to masts, sails, and furniture; which might be calculated to answer the purpose of the home-passage at the best season; and crews could be provided in India. Teak ships of 40 years old and upwards are not uncommon in the Indian seas, while an European ship is ruined there in five years. The teak is called the Indian oak. See TECTONA.

TEAKI, in *Geography*, an island in the Mediterranean; twenty miles long, and four broad. This island was anciently called "Ithaca," and is memorable in Grecian history for being the kingdom of Ulysses; some Europeans call it "Val de Compare." N. lat. 38° 47'. E. long. 21° 40'.

TEAL, QUERQUEDULA, in *Ornithology*, the *Anas crecca* of Linnæus, the smallest of all the duck kind. Its beak is black, and its head, and upper part of its neck, of a reddish-brown; but there runs on each side of the head a green streak from behind the eyes quite to the back part, and between these is a black spot under the eyes; there is a white line which separates the reddish colour from the green. The lower part of the neck, the shoulders, and the sides, are very beautifully variegated with black and white streaks; the breast and belly are of a dusky greyish-white; the first beautifully spotted with black; the vent black; the tail sharp-pointed and dusky; the coverts of the wings brown; the greater quill-feathers dusky; the exterior webs of the lesser marked with a glossy green spot, above which is another of black, and the tips white; the irides whitish, and the legs dusky. The female is of a brownish ash colour, spotted with black, and has a green spot on the wing, like the male. Ray and Pennant. See DUCK.

TEAL, *Crested, Querquedula cristata*, a name given by Bellonius and some others to a species of duck, remarkable for a tuft of feathers an inch and half long, hanging down from the back part of the head, and thence called the *tufted* duck; but more known among authors by the name of *capo negro*. See DUCK.

TEAL, *Summer, Anas circia* of Linnæus, is apprehended by Mr. Pennant to be no other than the female of our teal, though Linnæus has described it as a distinct species. See DUCK.

Summer teal is also a name given in some places to the garganey.

TEAM, THEAM, or Thame, in our *Ancient Customs*, signifies a royalty granted by the king's charter to a lord of a manor, for the having, restraining, and judging bondmen, neifs, and villeins, with their children, goods, and chattels, in his court.

TEAM, in *Agriculture*, the number of horses, oxen, or other animals which are drawing together at once in the same plough, cart, waggon, or other carriage. There is a great variety of different sorts of teams employed in field, road, and other sorts of labour, which is carried on by means of domestic animals; and it is of very great importance to ascertain which of them is of the greatest advantage, and the cheapest in the different uses and intentions.

In all sorts of farming work, in the field as well as on the road, the heavier kinds of strong horses, and those of the close, short, compact, punch breeds, have hitherto, for the most part, been employed for the purpose of team labour; and for

TEAM.

for the dray, and every sort of similar heavy work, where a slow, steady, strong draught is required, they are also unquestionably the most proper and suitable, as long experience has fully proved. But a considerable alteration has lately taken place in the kinds which are made use of as teams for carrying on the lighter sorts of road-work, whether by means of carriages or other vehicles.

It has been found that the stouter sort of horses, possessing a little blood, are by much the best adapted to this kind of labour of any, being much more active and expeditious, as well as more durable, and less liable to fatigue and to become tired out on the road. On this account they form the teams for most sorts of coach and other carriage labour, and in many instances for various heavier descriptions of it; and it is not improbable but that, in some cases, they might be substituted as teams for farming work with great propriety and advantage, in consequence of their quicker pace, and having what is commonly called more bottom.

Among farmers it has long been a disputed point, whether horses or oxen form the most economical and advantageous team for the purpose of the cultivator in performing his work, and it remains still undecided, though many intelligent agriculturalists now incline to the side of horse-teams, except in particular circumstances and situations. And a late writer has remarked, that the circumstances in which the latter have been chiefly supposed to be more advantageous than the former, are in their being kept at less expence, and their not declining in value. But that these, when examined, are perhaps not so decisive of their superiority, as they may at first sight appear; for where the work of the farm is done by the younger sort of horses, which is perhaps the best method, the decline in value cannot be of any material consequence, while the superiority in point of the dispatch of work is very great. And in regard to the keep, as oxen cannot perform their labour well in continuance without oats, or some other sustenance of a similar kind, it would seem not improbable but that young horses may pay nearly as well as oxen, and be kept with little difference in the expence. Indeed the common opinion, that oxen are superior to horses in the tillage of heavy lands, does not at all appear to be well founded, especially when drawn in *yokes* and *bows*, as the poaching must be greater than by horses working at length. But when in harness, they may, from their greater steadiness, be preferable; of course, under different management, they are capable of being employed in both ways. But in all such cases, as where quick motion is of more importance than the steady drawing of heavy weights, the horse is much superior to the ox, as well as in carting, where great speed is required in the unloaded state, and wherever the roads or lands are rough, sharp, and stony, as oxen cannot be shod so well as horses to stand such roads. And in harrowing with light harrows, where a jumping irregular motion is necessary, it has been shewn in the *Annals of Agriculture*, that horses are the most proper, and to be constantly preferred. In short, that teams of the ox-kind may be made use of with benefit in many cases in businesses about the farm, but they are incompatible with all sorts of distant work, and especially on the road, and in stony situations.

It has been remarked, in a late *Calendar of husbandry*, that there are two cases in which oxen are certainly more beneficial than horses: first, when a farmer lives in a district where there is a breed of cattle well adapted to work; and, secondly, when his farm is so large, that he can buy in a lot of cattle annually, at a small expence *per head*, and feel no inconvenience in turning out such beasts from the teams

to fatten as do not work well. In both these cases, the writer has little doubt of the superiority of oxen to horses. But in countries that do not possess a breed of cattle well adapted for work in the state of oxen; and on small farms, whence fairs must be attended at the distance of a hundred miles to purchase a few, and consequently at a great expence *per head*, and possibly without land for fattening any, the benefit will be very questionable.

It has been suggested by the writers of the *Agricultural Survey of the West Riding of Yorkshire*, that from the circumstances of ox-teams being almost universally given up in those places where they were formerly in repute, a suspicion arises, that working them is not attended with profit.

In regard to the national advantages to be derived from a change from horses to oxen, there does not appear to be any great benefit, as it has been shewn by Mr. Pitt in an excellent paper in the fifth volume of *Communications to the Board of Agriculture*, that as those used in agriculture are in a great measure a nursery for those wanted for other purposes; the extent of such change can take place no farther than about the work of 100,000 horses.

To ascertain what general effect such a change might produce in increasing food for mankind, as what he calls the higher kept farm-horses are generally, or at least a part of them in preparation for sale, for the road, or harness; he must suppose the deduction made, from what he has called moderately kept farm-horses; now supported at four acres and a half *per head*; then the deduction of

	Acres.
100,000 of those would save the landed produce of	450,000
And the deduction of young stock, in the same proportion, one-ninth of the whole, would save one-ninth of 250,000 acres, to preserve even numbers, suppose	30,000
In all saved	480,000

The idea in all the midland counties is, it is observed, that two oxen will be required to do the work of each horse; 200,000 working oxen will therefore be wanted instead of the horses thus deducted. To give the oxen a fair chance in this calculation, he will suppose them fit to work at three years old, and the workers to be of the ages of three, four, five, and six respectively, 50,000 of each; the same number coming one, two, and three years old, will be wanted for succession stock; and 50,000 annually fatted off; the land necessary for their support may be nearly as follows:

	Acres.
Keep of 50,000 steers, of the ages of coming one, two, and three years old respectively, 150,000 acres in all, at one acre each <i>per head per annum</i>	150,000
200,000 working oxen, of full three, four, five, and six years old, 50,000 of each, at two and a half acres <i>per head per annum</i>	500,000
Less land cannot, it is believed, be possibly allowed to keep them in working condition; they must have hay and sometimes corn when closely worked, 50,000 fattening, at three acres <i>per head</i>	150,000
Land necessary for the oxen	800,000
Deduct for the horses	480,000
Difference	320,000

These 320,000 acres of land will produce 50,000 fat oxen, or 32 acres will produce five fat oxen; suppose them 270lbs. *per quarter* each, or 5400lbs. of beef from 32 acres; this is 168 $\frac{3}{4}$ lbs. of beef *per acre per annum*: but a dairy will, it is said, produce more, and a flock of sheep well managed quite as much human food *per acre*. Little advantage, therefore, would, it is said, be derived from this change of substituting oxen for horses in agriculture, unless the use of horses on the road, and for purposes of pleasure, luxury, pomp, amusement, trade, mining, manufactures, commerce, and war, could be abolished or lessened.

Accordingly, Mr. Malthus thinks the advantages of luxury, when it falls short of actual vice, are certainly great: it cannot be denied, but it contributes to the comforts, enjoyments, and consequent happiness of a nation; but if carried too far, it will completely defeat its own purpose; the surest way is to stop short of the mark.

In the clear, full, and excellent account of the state of agriculture in the county of Middlesex, the very able and experienced author has brought together into one point of view a great number and variety of the different objections and reasons, which either operate against or wholly prevent the use of oxen for the purpose of performing team-labour; and which the inquirer, who wishes for more full information on so important a subject, may do well to consult, as they place the question with much clearness and decision greatly in favour, and on the side, of the horse.

In fact, the writer thinks it very clear, that those persons who prefer horses to oxen, for the purpose of labour, display superior knowledge in agriculture. This opinion, he says, is sanctioned by the practice of nine-tenths of the best husbandmen in the nation. In proportion as Britons become enlightened, they lay aside ox-teams; and experience has now so completely established the superiority of horses, as to render their employment almost universal. And under this system, the science and practice of agriculture have improved more rapidly than at any former period of time. "The number of horses used in husbandry are nearly," says the writer, "1,200,000. If half this number were to be superseded by oxen, in the proportion of two oxen to one horse, it would require 1,200,000 such cattle to do the same quantity of labour as is now done by 600,000 horses. The difference of these two numbers would be an increase to that extent of our labouring cattle. The other 600,000, in the place of so many horses, as well as the increased number, feed in the same manner as cows, and on a similar herbage; consequently the whole 1,200,000 would deprive us of the means of supporting so many cows. So unwise a measure would reduce the number of our cows to one-fourth of their present number. The veal, milk, butter, and cheese, would be diminished in that proportion; and in consequence of this scanty produce of the dairy, the price would be so exorbitant, that none but the most wealthy could afford to eat of these things.

"After what has been said, need I add, that every ox used in husbandry at this time deprives the nation of a cow, and of all the comforts which that animal is calculated to bestow. The introduction of oxen, to do one half the labour now done by horses, would deprive the labourers of the greater part of their diet: a dearth would be the inevitable consequence, until the numbers of our people were reduced to equal the scantiness of their food, or until the oxen could be fattened and slaughtered, to make way for the return of the more valuable cow. Hereafter I shall expect the farmers in theory only, who are advocates for ox-teams, to change their notes, and write in favour of a team to be drawn by cows."

Upon the whole, the writer is of opinion, that the very few advantages which oxen possess are not by any means of such consideration, as to compensate for the damage which their being used would do upon some kinds of land; nor are they so proper for the general purposes of a farm as horses, and the general substitution of labouring oxen in lieu of horses would be vastly injurious to the nation.

It is allowed that those who have argued in favour of the superior advantage of oxen may be correct in all their reasonings, so far as they are deduced from their own experience; but that the experience of others may furnish arguments as strong on the other side. Circumstances vary in every district, and render the good or the bad of any practice altogether relative. In the county of Chester, for instance, the farmer has not only to fallow his corn land, and lead manure to his meadows, but he has often to send his team to distances of ten or fifteen miles, to take his corn to market, to fetch lime or coal, and for various other purposes, on hard turnpike roads; and the time in which such services are performed is to him of essential consequence. Would oxen be as well able to accomplish such journeys as horses? Are oxen used in any county where circumstances are precisely similar? Do not oxen require more rest than horses? Will they stand hard work as well? Are they as ready for every different kind of work on a farm as horses? Unless these questions can be answered in the affirmative, we have to place in opposition to the saving of expence in keeping them, convenience and time, which are as valuable as corn and money. It is also further argued, that the diminution in the use of corn, from employing oxen, is an object of great national importance; all that the horse consumes being so much loss as the food of man; and the loss of animal food, occasioned by the preference given to horses, is likewise urged. But if, in the same portion of time, horses will do more work than oxen, the earth will be enabled to yield a greater produce, and the additional portion of food gained may more than counterbalance what is lost. The consumption of food, however, is not an argument which should be brought forward against the farmer, who, by every proper artificial means, should be induced to raise the greatest quantity possible from his ground. On what principle is it that the legislature, by bounties, endeavour to encourage exportation, when the prices of corn sink below a certain sum? Is it not that more may be produced, in the ordinary course of seasons, than the nation can consume, in order to secure a sufficiency when the harvests are below their average? The more horses are kept, the greater the consumption of corn, and the greater the demand; and is it not better to have it increased by such means, than by exportation? The horses, in the year of scarcity, may be fed entirely on hay or grass; and, at all times, their existence is so much real national wealth. May it not be doubted too, whether, if farmers could dispense with the use of horses, a sufficient number would, as hinted at above, be reared for the mere purposes of pleasure or luxury, to answer the demand of government, in cases of emergency? Numbers of them, of all descriptions, whether for the increase of cavalry, or the draught of artillery, are surely desirable in every country that must trust its defence exclusively to its own exertions. Even now the breeding of them is attended with so much hazard, that very many are fearful of encountering the risk: what then would be the consequence, if the demand was considerably lessened?

In respect to the feeding of teams, whether of horses or oxen, it is a point that requires much thought, care, and attention; as where a want of economy prevails, it may lessen the profits of the farmer in a very high de-

gree, as is obvious from the vast consumption of expensive food that must take place. The yearly expence of keeping a labouring horse and an ox, previous to the late rise in the different articles that are made use of as food, has been stated, in the sixteenth volume of the *Annals of Agriculture*, to be in the general amount as follows: *viz.* that of a working horse, 17*l.* 10*s.* 6*d.*; and that of a working ox, 13*l.* 1*s.* 10*d.*: so that the difference of expence in favour of the ox is 4*l.* 8*s.* 8*d.*

The difference in the expences of food, since the above period, may have probably demanded the addition of rather more than one-third to these accounts; though they are at present much lowered.

The training or breaking in the oxen for team-labour is commonly performed by first confining them by means of a halter or rope, while the yoke or harness is put on, and then placing them between a pair of old steady oxen both before and behind, so that they can neither push forward nor backward in an improper manner; and another, perhaps better, way is to yoke them singly with an old team-ox, which is not a free worker, as they are less liable to be hurt in hot weather in this way. They may also be first broken in, by being employed in other sorts of labour before they are put to the plough.

Oxen are more apt to tread, poach, and injure the land, especially where it is of a heavy, clayey, moist nature, when worked in yokes, than when in harness; yet some districts prefer the system of yokes and bows, either single or double, to the harness method, which is a later practice. And there is a wide difference of opinion among practical farmers about the superiority of the one or the other method. Some very sensible men, who have tried both ways, contend that three in harness are equal to as much work as four in the other mode, and that they are more quick in their motions, and work with more ease: while others, equally well experienced, are decidedly of opinion that the old established method is superior to the new, and that any number in yokes are equal to the same number in collars. The question is, of course, not yet well decided: however, it is agreed, that it is unfavourable to work them too hard in any method.

The necessary proportion of horses to the extent of the farm, is also a circumstance that is of much interest to the farmer; but which must of necessity vary greatly, according to the nature, situation, and state of the land, as well as the mode of husbandry under which it is conducted.

In deciding the necessary proportion of team, the farmer must likewise well consider the extent which the sward or grass-land bears to that which is in the state of tillage; as where the proportion of the former is considerable, there will be much less team-work to be executed, of course a much less strength may be sufficient. Where the farm is under the hay system, as there is seldom much team-work, except in conveying the produce and carting manure, a smaller extent of team is mostly sufficient, in proportion to the quantity of land, than in other cases. And in the dairy management, the same is the case; but as in this case it becomes necessary to raise green crops as cattle food, a somewhat stronger team may be required than in the former case.

In perfectly tillage farms, whether conducted under the naked fallow system, or the more improved management under the convertible husbandry, a much greater force of team will be required, in proportion to the extent of land that is to be cultivated. Some reduction of team-labour may, however, be effected in both cases, by having recourse

to green smothering crops in the place of the fallowings, which should always be done as much as possible.

There can be no doubt but that there are some other sorts of animals, besides those of the horse and ox kind, that may be occasionally employed in team-labour. The mule is an animal well calculated for this purpose, from its being more hardy, and enduring work a greater length of time, or to a more advanced age, than the horse. In some cases, the smaller sorts of mules have been recommended, as more hardy and useful; but in Worcestershire, large mules have been found more beneficial for team purposes.

The ass may likewise be employed for team-labour with advantage, in small concerns, from its hardy nature, and being capable of living on more scanty fare than the horse; and it is very useful for numerous purposes about the farm-house.

Whatever sort of teams may be made use of upon farms, they should always be well attended to, and no neglect of any kind suffered in regard to them; and when attacked by disease, recourse be had as quickly as possible to proper remedies.

TEAN, in *Geography*, a river of England, which runs into the Dove, 2 miles N.E. of Uttoxeter.

TEANO, a town of Naples, in Lavora; 14 miles N.W. of Capua.

TEANUM, TIANO, in *Ancient Geography*, a town of Italy, in Campania, towards the south-east. It was a Roman colony, and a considerable town.—Also, a town of Italy, surnamed Apulum by Strabo, and Apulorum by Pliny.

TEAP, in *Rural Economy*, provincially a tup or ram. See RAM.

TEARNE, in *Geography*, a river of England, which runs into the Severn, near Shrewsbury.

TEARPOUR, a town of Hindoostan, in the circar of Sumbul; 13 miles N.N.E. of Sumbul.

TEARS, in *Physiology*, the peculiar limpid fluid secreted by the lacrymal gland. This fluid is destined to preserve the transparency of the cornea, by keeping it moist, and removing from it foreign substances. In man a preternatural flow of tears is excited by different passions of the mind, especially grief; but it is doubtful if this takes place in any inferior animal. See EYE, MAN, and PASSION.

The fluid of tears has been examined *chemically* by Fourcroy and Vauquelin, but their account of its properties is not so complete as could be wished. It is colourless and transparent, without any smell, but of a perceptibly saline taste. Its specific gravity is somewhat greater than that of water. It tinges vegetable blues green. It unites with water, both cold and hot, in every proportion. The mineral acids produce no change upon it. When evaporated to dryness, a number of cubic crystals of muriate of soda are obtained; and there are also distinct traces of a free alkali, which is soda. One hundred parts, when evaporated, leave only four of solid matter, of which about one is saline matter, and the rest a peculiar animal substance, which these chemists considered as a species of *mucus*, and which is separated likewise from tears in their fluid state, in the form of flakes, when alcohol is poured upon them. This peculiar animal matter, on exposure to the air, is stated to possess the property of gradually absorbing oxygen, which renders it thick and viscid, and of a yellow colour. In this state it is insoluble in water, and remains long suspended in it without alteration. Hence, says Berzelius, if these observations are to be depended upon, this substance bears a considerable affinity to the mucus of the nose, which probably, like that

lake Tasse; their channels are deep, and they are connected by streams from the lake Tasse. The Teche is much larger and longer than the other, being upwards of 200 miles in length. The Tasse is a beautiful lake of clear water, about 10 miles in circumference. The principal settlements of the Attakapas are on each side of the Teche, mostly western, and on the Vermillion. Besides the culture of cotton, maize, &c. they have the advantage of extensive natural meadows to support their herds, which, on account of the natural mildness of the climate, are kept without much trouble. The inhabitants of the Attakapas are generally wealthy, and live as luxuriantly as the planters of the Mississippi. Upon the whole, this part of Louisiana seems destined to become one of its richest districts.

TECHIA, a town of the Arabian Irak; 160 miles N. of Bagdad.

TECHNICAL, TECHNICUS, formed of τεχνικος, *artificial*, of τεχνη, *art*, something that relates to art.

In this sense we say, *technical words, technical verses, &c.* And in this sense Dr. Harris entitles his dictionary of arts and sciences, *Lexicon Technicum*.

TECHNICAL is more particularly applied to a kind of verses, in which are contained the rules or precepts of any art, thus digested to help the memory to retain them. See *Artificial MEMORY*.

Technical verses are used in chronology, &c. Such, *e. gr.* are those expressing the order and measure of the calends, nones, &c. those expressing the seasons, and those expressing the order, &c. of the signs.

F. Labbé has composed a set of technical Latin verses, including all the epochs in chronology; and F. Buffier, after his example, has put both chronology and history into French verse, and even geography also.

Technical verses are commonly composed in Latin; they are generally wretched ones, and often barbarous; but utility is all that is aimed at in them: to give some idea of which we will here add a few instances. The casuists include all the circumstances which make us partakers with another in a theft, or other crime, in these two technical verses.

“Jussio, consilium, consensus, palpo, recursus,
Participans, mutus, non obitans, non manifestans.”

The first of F. Buffier's technical verses of the history of France, are these:

“Ses lois en quatre cents Pharamond introduit,
Clodion Chevelu, qu' Actius vanquit.
Merovée; avec lui combatit Attila;
Childeric fut chassé, mais on le repella.”

TECHNICAL Words, are what we otherwise call *terms of art*.

TECHUKS, in *Geography*, the most remote people of Asiatic Russia, who scarcely exceed 1000 families, are generally found in small camps, pitched by the sides of rivers. Their rude tents are square, consisting of four poles, supporting skins of rein-deer, which also form the covering: before every tent are spears, and arrows, fixed in the snow against any sudden attacks of the Koriaks, who, though of the same race, are a more malicious and enterprising people. In the middle is a stove, and the bed consists of small branches of trees spread on the snow, and covered with deer-skins. Their habitations and food are dirty and disgusting; and the dress of the women consists only of a single deer-skin fastened on the neck, so that on loosening one knot the body remains naked. The features are coarse, but they have not the flat noses, nor little hollow eyes of the Kamtchadales; and Lesseps pronounces their countenances to have nothing of

the Asiatic form, in which assertion he had been preceded by Pallas and Tooke. The Koriaks are supposed not to exceed 2000 families.

TECKLENBURG, a town of Westphalia, and capital of a county to which it gives name; 7 miles S.W. of Osnabruck. N. lat. 52° 15'. E. long. 7° 35'.—Also, a county and principality, bounded on the north and east by the bishopric of Osnabruck, and on the south and west by the bishopric of Munster; about 20 miles in length, and 10 in breadth: This county was formerly more extensive, including the county of Linggen, and part of the bishopric of Munster. The soil is fertile, and yields good corn, and pastures for cattle: the river abounds in fish, and in several places are quarries of stone: the chief manufactures are linen cloth. It is now annexed to Westphalia.

TECLITIUM, or TEGLIITIUM, in *Ancient Geography*, a town of Lower Mœsia, upon the route from Vinmatium to Nicomedia, along the Danube. Anton. Itin.

TECOANTAPEQUE, in *Geography*, a sea-port town of Mexico, in the province of Guaxaca, situated at the foot of a volcanic mountain, near the Pacific ocean; 160 miles S.E. of Acapulco. N. lat. 16° 2'. W. long. 99° 10'.

TECOLATA, or TETOLATA, in *Ancient Geography*, a town of Gallia Narbonensis, upon the Valerian way, between Ad Turrem and Aquæ Sextiæ. Anton. Itin.

TECOLITHOS, in *Natural History*, the name of a gem, otherwise called *Syriacus lapis*, and *Judaicus lapis*, good for dissolving the human calculus. See SYRIACUS and JUDAICUS.

It has this name from τικω, *I dissolve*, and λιθος, *a stone*; because it dissolves stones.

TECOMA, in *Botany*, so called by Jussieu, from the Mexican appellation *Tecomaxochitl*, under which one of the species appears in Hernandez.—Juss. 139. Brown Prodr. Nov. Holl. v. 1. 471. (*Tecomaxochitl* alia; Hernand. Mex. 409.)—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Perfonate*, Linn. *Bignoniæ*, Juss. *Bignoniaceæ*, Brown.

This genus is separated from *Bignonia* by Jussieu, solely because the partition of the capsule or pod is contrary, not parallel, to the valves; and he enumerates as species the *B. flans*, *radicans*, and *pentaphylla* of Linnaeus, besides the above plant of Hernandez from Mexico. Mr. Brown adds to these the *B. pandorana*, Andr. Repof. t. 86; which is *B. Pandoræ*, Curt. Mag. t. 865; *B. pandoræ*, Venten. Malmaif. t. 43; though the last-mentioned author says he found the partition of the capsule parallel to the valves, and therefore this species is a *Bignonia* according to Jussieu. So indeed it remains in Mr. Aiton's Hort. Kew. v. 4. 34, with the specific name of *australis*, by the substitution of which Mr. Brown has happily got rid of the above *pandorean* confusion; and there we shall readily leave it, only remarking that it is, according to Mr. Brown, a native of Port Jackson, and of the tropical part of New Holland, not of Norfolk island. The stem is twining. Leaves pinnate, with an odd leaflet, smooth. Flowers panicled, white, with a purple throat. For the other species above named, see BIGNONIA, n. 11, 14 and 15. We doubt whether the tribe in question is sufficiently well known at present for botanists to undertake its generic reformation. Nor can we permit the above name of our distinguished friend Jussieu to pass without animadversion, as nothing can be more contrary to sound principles of nomenclature, nor to his own declaration against barbarous names in his preface. The present is peculiarly ill applied, as the original *Tecomaxochitl* of Hernandez appears to be *Selandra grandiflora*, or very like it, having simple leaves.

TECONA,

TECONA, in *Geography*, a town of Hindoostan, in Dow-latabad; 21 miles W. of Poonah.

TECONIC FALLS, a cataract in the river Kennebeck, about 65 miles from its mouth.

TECORIPA, a town of New Mexico, in the province of Sonora; 70 miles E. of Pitquin.

TECRIT, a town of Asiatic Turkey, in the government of Mosul, situated on a rock near the west side of the Tigris, on the borders of the Arabian Irak. Tecrit is thought to be the Birtha or Vitra of the ancients, described as a very strong fortress, and said to have been constructed by Alexander the Great. It was chosen in the seventh century for the abode of a Jacobite primate, and increased to a considerable town. In 1393, it was taken by Timur Bec, who put all the soldiers that defended it to death. The ruins are extensive, and the number of houses amount to about five or six hundred, with a caravansera and two coffee-houses; 120 miles S. of Mosul. N. lat. $34^{\circ} 37'$. E. long. $42^{\circ} 37'$.

TECTONA, in *Botany*, a name altered by Linnæus from the East Indian name of this valuable timber-tree, *Tek*, *Tekka*, *Theka*, or *Teak*, and made classical, according to a method which he sometimes used, from *τεκτων*, a carpenter, or *τεκτονα*, a piece-work in timber, or iron, both derived from *τεκνω*, to build; alluding to the use of the wood in building houses as well as ships.—Linn. Suppl. 20. Schreb. 141. Willd. Sp. Pl. v. 1. 1088. Mart. Mill. Dict. v. 4. Thunb. Nov. Gen. diss. 4. 71. Ait. Hort. Kew. v. 2. 11. Gærtn. t. 57. (Theka; Juss. 108. Lamarck Illustr. t. 136.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Personate*, Linn. *Vitices*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, its margin in five, occasionally six, ovate blunt segments, permanent. Cor. of one petal, funnel-shaped; tube shorter than the calyx; limb in five, occasionally six, deep, obovate, crenate segments, incurved at the point, twice as long as the tube. Nectary a glandular ring, at the base of the germen. Stam. Filaments as many as the segments of the corolla, inserted, alternately therewith, into the tube, decurrent, thread-shaped, erect, rather longer than the limb; anthers heart-shaped; two-lobed, erect. Pist. Germen superior, nearly globular, downy; style thread-shaped, downy, slightly curved, the length of the corolla; stigmas two, revolute, obtuse. Peric. Drupa nearly globose, depressed, dry, spongy, hairy, concealed in the enlarged, inflated, membranous calyx. Seed. Nut bony, the shape of the drupa, with a terminal knob, of four cells, with solitary kernels.

Ess. Ch. Corolla five-cleft. Stigma divided. Drupa dry, spongy, within the inflated calyx. Nut of four cells.

Obf. The terminal flowers are often six-cleft.

1. *T. grandis*. Teak-wood, or Indian Oak. Linn. Suppl. 151. Willd. n. 1. Ait. n. 1. Roxb. Coromand. v. 1. 10. t. 6. (Theka; Rheede Hort. Malab. v. 4. 57. t. 27. Jatus; Rumph. Amboin. v. 3. 34. t. 18.)—Native of the mountainous parts of the Malabar and Coromandel coasts, as well as of Java, Ceylon, and other countries of the East Indies, flowering during the hot season; but not till the tree is arrived at a considerable age and magnitude, so that there is little chance of seeing it blossom in our stoves, where young plants are sometimes introduced. The trunk in its native country grows erect, to a vast height, with copious spreading opposite branches, crossing each other, quadrangular when young. Leaves spreading, opposite, stalked, elliptic-oblong, acute, entire, slightly waved, with one rib and many transverse veins, whose subdivisions are finely reticulated; their upper side rough like a file; lower finely downy: their length is generally about a span, but

the leaves on young branches sometimes measure eighteen inches or two feet, and are nearly half as much in breadth. Panicles terminal, hoary, very large and spreading, repeatedly subdivided in an opposite manner, with lanceolate bractæ. Flowers very numerous, comparatively small, being scarcely half an inch long; externally hoary; internally yellow, dotted with red. Anthers yellow. Fruit the size of a small cherry, rough, brown, in a large membranous, brown, bladder-like calyx, resembling the *Physalis Alkegengi* in general shape, but hardly so large.

The wood of this tree is, as Dr. Roxburgh remarks, by far the most useful timber in Asia; it is light, easily worked, and though porous, both strong and durable. For ship-building it is peculiarly excellent for its lightness, and its durability either in or out of the water. Pegu affords the largest quantity of this timber, which is easily brought down the rivers of that country, and sold cheap. The same author mentions that the banks of the Godavery, in Hindoostan, afford a teak which is beautifully veined, much closer in the grain, and heavier, than usual. This sort is peculiarly fitted for furniture, and gun-carriages.—Teak-wood, according to Thunberg, fetches a considerable price at the Cape of Good Hope, on account of its great utility, in a country where large timber-trees are rare.

TECTOSAGES, or *Volce Tectosages*, in *Ancient Geography*, a people included amongst those who inhabited the southern part of Gaul, belonging more particularly to Languedoc.

TECTRICES, in *Ornithology*, are the lesser coverts of the wings of birds, or the feathers which lie on the bones of the wings.

TECUCZI, or **TECUTSCH**, in *Geography*, a town of European Turkey, in Moldavia, on the Birlat; 70 miles W.N.W. of Galatz.

TECULET, a town of Africa, in the empire of Morocco, situated near the coast of the Atlantic, on the edge of a mountain. In the year 1514, this town was sacked by the Portuguese, and a great number of inhabitants carried away for slaves. It has been since re-peopled; 15 miles E. of Mogodor.

TECUM DUCES. See **DUCES**.

TED, in *Agriculture*, a term made use of to signify the spreading abroad new-mown grass, which is the first thing done in order to its being dried, and made into hay. Much in the process of hay-making depends upon good and complete tedding of the grassy hay in the beginning of the work.

TEDANIUM, **TEDONIUS**, or *Tidanus*, in *Ancient Geography*, a river of Illyria, which served as a boundary between this province and Japygia. Pliny.

TEDBURY, in *Geography*. See **TETBURY**.

TEDDER, **TEDDOR**, or *Tether*, in *Agriculture*, a rope or chain by which an animal is tied, and confined in the fields, that it may not pasture on too wide a range. This is very seldom a good practice, or one that should be much followed.

TEDELER, or **TEDLIS**, in *Geography*. See **DELLYS**.

TEDESCHI, or **TUDESCHI**, **NICCOLO**, in *Biography*, an eminent canonist, sometimes called "the abbot," and sometimes "Panormitanus," from the city of Palermo, the city in which, as some say, he was born, in 1386, though others make Catania his native place. At the age of fourteen he took the habit of St. Benedict in Catania, and afterwards pursued his studies at Bologna. We shall not follow him through all the stages of his advancement from one degree of reputation, and from one station of honour and trust

lake Tasse; their channels are deep, and they are connected by streams from the lake Tasse. The Teche is much larger and longer than the other, being upwards of 200 miles in length. The Tasse is a beautiful lake of clear water, about 10 miles in circumference. The principal settlements of the Attakapas are on each side of the Teche, mostly western, and on the Vermillion. Besides the culture of cotton, maize, &c. they have the advantage of extensive natural meadows to support their herds, which, on account of the natural mildness of the climate, are kept without much trouble. The inhabitants of the Attakapas are generally wealthy, and live as luxuriantly as the planters of the Mississippi. Upon the whole, this part of Louisiana seems destined to become one of its richest districts.

TECHIA, a town of the Arabian Irak; 160 miles N. of Bagdad.

TECHNICAL, TECHNICAL, formed of τεχνικος, *artificial*, of τεχνη, *art*, something that relates to art.

In this sense we say, *technical words, technical verses, &c.* And in this sense Dr. Harris entitles his dictionary of arts and sciences, *Lexicon Technicum*.

TECHNICAL is more particularly applied to a kind of verses, in which are contained the rules or precepts of any art, thus digested to help the memory to retain them. See *Artificial MEMORY*.

Technical verses are used in chronology, &c. Such, *e. gr.* are those expressing the order and measure of the calends, nones, &c. those expressing the seasons, and those expressing the order, &c. of the signs.

F. Labbé has composed a set of technical Latin verses, including all the epochs in chronology; and F. Buffier, after his example, has put both chronology and history into French verse, and even geography also.

Technical verses are commonly composed in Latin; they are generally wretched ones, and often barbarous; but utility is all that is aimed at in them: to give some idea of which we will here add a few instances. The casuists include all the circumstances which make us partakers with another in a theft, or other crime, in these two technical verses.

“Jussio, consilium, consensus, palpo, recurfus,
Participans, mutus, non obitans, non manifestans.”

The first of F. Buffier's technical verses of the history of France, are these:

“Ses lois en quatre cents Pharamond introduit,
Clodion Chevelu, qu' Actius vanquit.
Merovée; avec lui combatit Attila;
Childeric fut chassé, mais on le repella.”

TECHNICAL Words, are what we otherwise call *terms of art*.

TECHUKS, in *Geography*, the most remote people of Asiatic Russia, who scarcely exceed 1000 families, are generally found in small camps, pitched by the sides of rivers. Their rude tents are square, consisting of four poles, supporting skins of rein-deer, which also form the covering: before every tent are spears, and arrows, fixed in the snow against any sudden attacks of the Koriaks, who, though of the same race, are a more malicious and enterprising people. In the midst is a stove, and the bed consists of small branches of trees spread on the snow, and covered with deer-skins. Their habitations and food are dirty and disgusting; and the dress of the women consists only of a single deer-skin fastened on the neck, so that on loosening one knot the body remains naked. The features are coarse, but they have not the flat noses, nor little hollow eyes of the Kamtchadales; and Lesseps pronounces their countenances to have nothing of

the Asiatic form, in which assertion he had been preceded by Pallas and Tooke. The Koriaks are supposed not to exceed 2000 families.

TECKLENBURG, a town of Westphalia, and capital of a county to which it gives name; 7 miles S.W. of Osnabruck. N. lat. 52° 15'. E. long. 7° 35'.—Also, a county and principality, bounded on the north and east by the bishopric of Osnabruck, and on the south and west by the bishopric of Munster; about 20 miles in length, and 10 in breadth: This county was formerly more extensive, including the county of Lingen, and part of the bishopric of Munster. The soil is fertile, and yields good corn, and pastures for cattle: the river abounds in fish, and in several places are quarries of stone: the chief manufactures are linen cloth. It is now annexed to Westphalia.

TECLITIUM, or TEGLITIUM, in *Ancient Geography*, a town of Lower Mæsia, upon the route from Vininatium to Nicomedia, along the Danube. Anton. Itin.

TECOANTAPEQUE, in *Geography*, a sea-port town of Mexico, in the province of Guaxaca, situated at the foot of a volcanic mountain, near the Pacific ocean; 160 miles S.E. of Acapulco. N. lat. 16° 2'. W. long. 99° 10'.

TECOLATA, or TETOLATA, in *Ancient Geography*, a town of Gallia Narbonensis, upon the Valerian way, between Ad Turrem and Aquæ Sextiæ. Anton. Itin.

TECOLITHOS, in *Natural History*, the name of a gem, otherwise called *Syriacus lapis*, and *Judaicus lapis*, good for dissolving the human calculus. See *SYRIACUS* and *JUDAICUS*.

It has this name from *τεκω*, *I dissolve*, and *λιθος*, *a stone*; because it dissolves stones.

TECOMA, in *Botany*, so called by Jussieu, from the Mexican appellation *Tecomaxochitl*, under which one of the species appears in Hernandez.—Juss. 139. Brown Prodr. Nov. Holl. v. 1. 471. (*Tecomaxochitl* alia; Hernand. Mex. 409.)—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personate*, Linn. *Bignonia*, Juss. *Bignoniaceæ*, Brown.

This genus is separated from *Bignonia* by Jussieu, solely because the partition of the capsule or pod is contrary, not parallel, to the valves; and he enumerates as species the *B. flans*, *radicans*, and *pentaphylla* of Linnaeus, besides the above plant of Hernandez from Mexico. Mr. Brown adds to these the *B. pandorana*, Andr. Repof. t. 86; which is *B. Pandora*, Curt. Mag. t. 865; *B. pandorea*, Venten. Malmaif. t. 43; though the last-mentioned author says he found the partition of the capsule parallel to the valves, and therefore this species is a *Bignonia* according to Jussieu. So indeed it remains in Mr. Aiton's Hort. Kew. v. 4. 34, with the specific name of *australis*, by the substitution of which Mr. Brown has happily got rid of the above *pandorean* confusion; and there we shall readily leave it, only remarking that it is, according to Mr. Brown, a native of Port Jackson, and of the tropical part of New Holland, not of Norfolk island. The stem is twining. Leaves pinnate, with an odd leaflet, smooth. Flowers panicled, white, with a purple throat. For the other species above named, see *BIGNONIA*, n. 11, 14 and 15. We doubt whether the tribe in question is sufficiently well known at present for botanists to undertake its generic reformation. Nor can we permit the above name of our distinguished friend Jussieu to pass without animadversion, as nothing can be more contrary to sound principles of nomenclature, nor to his own declaration against barbarous names in his preface. The present is peculiarly ill applied, as the original *Tecomaxochitl* of Hernandez appears to be *Scandria grandiflora*, or very like it, having simple leaves.

TECONA,

TECONA, in *Geography*, a town of Hindoostan, in Dowatabad; 21 miles W. of Poonah.

TECONIC FALLS, a cataract in the river Kennebeck, about 65 miles from its mouth.

TECORIPA, a town of New Mexico, in the province of Sonora; 70 miles E. of Pitquin.

TECRIT, a town of Asiatic Turkey, in the government of Mosul, situated on a rock near the west side of the Tigris, on the borders of the Arabian Irak. Tecrit is thought to be the Birtha or Vitra of the ancients, described as a very strong fortress, and said to have been constructed by Alexander the Great. It was chosen in the seventh century for the abode of a Jacobite primate, and increased to a considerable town. In 1393, it was taken by Timur Bec, who put all the soldiers that defended it to death. The ruins are extensive, and the number of houses amount to about five or six hundred, with a caravansera and two coffee-houses; 120 miles S. of Mosul. N. lat. 34° 37'. E. long. 42° 37'.

TECTONA, in *Botany*, a name altered by Linnæus from the East Indian name of this valuable timber-tree, *Tek*, *Tekka*, *Theka*, or *Teak*, and made classical, according to a method which he sometimes used, from τεκτων, a carpenter, or τεκτονα, a piece-work in timber, or iron, both derived from τεκνω, to build; alluding to the use of the wood in building houses as well as ships.—Linn. Suppl. 20. Schreb. 141. Willd. Sp. Pl. v. 1. 1088. Mart. Mill. Dict. v. 4. Thunb. Nov. Gen. diff. 4. 71. Ait. Hort. Kew. v. 2. 11. Gærtn. t. 57. (Theka; Juss. 108. Lamareck Illustr. t. 136.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Personate*, Linn. *Vitices*, Juss.

Gen. Ch. Cal. Perianth inferior, of one leaf, bell-shaped, its margin in five, occasionally six, ovate blunt segments, permanent. Cor. of one petal, funnel-shaped; tube shorter than the calyx; limb in five, occasionally six, deep, obovate, crenate segments, incurved at the point, twice as long as the tube. Nectary a glandular ring, at the base of the germen. Stam. Filaments as many as the segments of the corolla, inserted, alternately therewith, into the tube, decurrent, thread-shaped, erect, rather longer than the limb; anthers heart-shaped; two-lobed, erect. Pist. Germen superior, nearly globular, downy; style thread-shaped, downy, slightly curved, the length of the corolla; stigmas two, revolute, obtuse. Peric. Drupa nearly globose, depressed, dry, spongy, hairy, concealed in the enlarged, inflated, membranous calyx. Seed. Nut bony, the shape of the drupa, with a terminal knob, of four cells, with solitary kernels.

Eff. Ch. Corolla five-cleft. Stigma divided. Drupa dry, spongy, within the inflated calyx. Nut of four cells.

Obs. The terminal flowers are often six-cleft.

1. *T. grandis*. Teak-wood, or Indian Oak. Linn. Suppl. 151. Willd. n. 1. Ait. n. 1. Roxb. Coromand. v. 1. 10. t. 6. (Theka; Rheede Hort. Malab. v. 4. 57. t. 27. Jatus; Rumph. Amboin. v. 3. 34. t. 18.)—Native of the mountainous parts of the Malabar and Coromandel coasts, as well as of Java, Ceylon, and other countries of the East Indies, flowering during the hot season; but not till the tree is arrived at a considerable age and magnitude, so that there is little chance of seeing it blossom in our stoves, where young plants are sometimes introduced. The trunk in its native country grows erect, to a vast height, with copious spreading opposite branches, crossing each other, quadrangular when young. Leaves spreading, opposite, stalked, elliptic-oblong, acute, entire, slightly waved, with one rib and many transverse veins, whose subdivisions are finely reticulated; their upper side rough like a file; lower finely downy: their length is generally about a span, but

the leaves on young branches sometimes measure eighteen inches or two feet, and are nearly half as much in breadth. Panicles terminal, hoary, very large and spreading, repeatedly subdivided in an opposite manner, with lanceolate bracts. Flowers very numerous, comparatively small, being scarcely half an inch long; externally hoary; internally yellow, dotted with red. Anthers yellow. Fruit the size of a small cherry, rough, brown, in a large membranous, brown, bladder-like calyx, resembling the *Physalis Alkegenzi* in general shape, but hardly so large.

The wood of this tree is, as Dr. Roxburgh remarks, by far the most useful timber in Asia; it is light, easily worked, and though porous, both strong and durable. For ship-building it is peculiarly excellent for its lightness, and its durability either in or out of the water. Pegu affords the largest quantity of this timber, which is easily brought down the rivers of that country, and sold cheap. The same author mentions that the banks of the Godavery, in Hindoostan, afford a teak which is beautifully veined, much closer in the grain, and heavier, than usual. This sort is peculiarly fitted for furniture, and gun-carriages.—Teak-wood, according to Thunberg, fetches a considerable price at the Cape of Good Hope, on account of its great utility, in a country where large timber-trees are rare.

TECTOSAGES, or *Volce Teetosages*, in *Ancient Geography*, a people included amongst those who inhabited the southern part of Gaul, belonging more particularly to Languedoc.

TECTRICES, in *Ornithology*, are the lesser coverts of the wings of birds, or the feathers which lie on the bones of the wings.

TECUCZI, or **TECUTSCH**, in *Geography*, a town of European Turkey, in Moldavia, on the Birlat; 70 miles W.N.W. of Galatz.

TECULET, a town of Africa, in the empire of Morocco, situated near the coast of the Atlantic, on the edge of a mountain. In the year 1514, this town was sacked by the Portuguese, and a great number of inhabitants carried away for slaves. It has been since re-peopled; 15 miles E. of Mogodor.

TECUM DUCES. See **DUCES**.

TED, in *Agriculture*, a term made use of to signify the spreading abroad new-mown grass, which is the first thing done in order to its being dried, and made into hay. Much in the process of hay-making depends upon good and complete tedding of the grassy hay in the beginning of the work.

TEDANIUM, **TEDONIUS**, or *Tidanus*, in *Ancient Geography*, a river of Illyria, which served as a boundary between this province and Japygia. Pliny.

TEDBURY, in *Geography*. See **TETBURY**.

TEDDER, **TEDDOR**, or *Tether*, in *Agriculture*, a rope or chain by which an animal is tied, and confined in the fields, that it may not pasture on too wide a range. This is very seldom a good practice, or one that should be much followed.

TEDELER, or **TEDLIS**, in *Geography*. See **DELLYS**.

TEDESCHI, or **TUDESCHI**, **NICCOLO**, in *Biography*, an eminent canonist, sometimes called "the abbot," and sometimes "Panormitanus," from the city of Palermo, the city in which, as some say, he was born, in 1386, though others make Catania his native place. At the age of fourteen he took the habit of St. Benedict in Catania, and afterwards pursued his studies at Bologna. We shall not follow him through all the stages of his advancement from one degree of reputation, and from one station of honour and trust

to another; but observe, that he accepted a cardinal's hat from pope Felix V., favoured by Alphonso, king of Sicily, and openly embraced his party during the contests about the papal throne. In 1442 he was pope's legate to Frederic, king of the Romans; but when Alphonso took part with pope Eugenius, Tedeschi retired to his church at Palermo, of which he was archbishop. He would not divest himself of the purple, though received from an anti-pope, but died possessed of it in 1445. Of the erudition of this ecclesiastic, however fluctuating and temporising he was in his politics, we have ample evidence in his works, an edition of which was published at Venice, in 9 vols. fol., in 1617.

TEDESCHINI, CHRISTIANI, a buffo tenor singer in the comic opera, who came hither from Berlin at the same time as the Paganini, 1760. He appeared first in an under character in "Il Mondo nella Luna," composed by Galuppi. Nor was his figure (which was *gobbo*) or voice fit for a more important part. He was, we believe, by birth a German, whence he had his name; but he had been in Italy, and his language on the stage, and manner of singing, were perfectly Italian.

He sung on our opera stage but one year, and afterwards devoted his time totally to scholars, and became a very fashionable and useful singing-master. Among his numerous pupils he made many good singers, the Miss Fitzpatrick's, Miss Sloper, &c. &c.; and was of use to many of our stage-singers. After accumulating a considerable sum of money by diligence and hard labour, he returned to the continent to end his days.

TE DÉUM, a kind of hymn, or song of thanksgiving, used in the church, beginning with the words *Te Deum laudamus, We praise thee, O God.*—It is usually supposed to be the composition of St. Augustine and St. Ambrose.

It is customarily sung in the Romish church with extraordinary pomp and solemnity upon the gaining of a battle, or other happy event: and sometimes even to conceal a defeat.

This hymn was likewise sung in Protestant churches on days of thanksgiving for a victory, peace, or other national event. Purcell composed his *Te Deum* for the opening of the cathedral of St. Paul's, but did not live till that structure was finished.

In Boyer's Annals of Queen Anne, vol. iv., 1704, it is said that the hymn *Te Deum*, with other anthems, were admirably performed at St. Paul's, when her majesty went thither in great state on the day of thanksgiving for the victory at Blenheim. We are not informed by whom the music was composed; it is only said that it was performed with great solemnity by the three choirs of her majesty's chapel, Westminster Abbey, and St. Paul's. There was no instrumental band on this occasion, or any other accompaniment to the voices than the organ, which seems to have been the case in all former times, when any of our sovereigns went in state to St. Paul's.

But in 1706 we are told in the same Annals, vol. v. p. 333, that at a public thanksgiving for the battle of Ramillies, her majesty went in great ceremony to St. Paul's, accompanied by both houses of parliament, and all the great officers of state; when *Te Deum* was performed "with vocal and instrumental music, after the composition of the famous Mr. Henry Purcell." And this seems the first time that an instrumental band was allowed to accompany the voices in our metropolitan church of St. Paul.

In 1708, *Te Deum* was sung to excellent music at St. Paul's, composed by Dr. Crofts for the victory at Audenarde, whither her majesty went in great solemnity.

We were extremely curious to learn when and where Handel's grand *Te Deum* for the peace of Utrecht was first performed. It was natural to imagine that it was first heard at St. Paul's, and that queen Anne went thither in state on the occasion, which sir John Hawkins positively asserts, telling us that, "in 1713, the treaty of peace at Utrecht being finished, a public thanksgiving was ordered for the occasion, and Mr. Handel received from the queen a command to compose a *Te Deum* and Jubilate, which were performed at St. Paul's cathedral, her majesty herself attending the service." Hist. Mus. vol. v. p. 269.

But though in a paragraph of the Post Boy, July 2, 1713, it is announced that "her majesty goes the 7th to St. Paul's, being the day appointed for the thanksgiving, accompanied by the houses of the lords and commons;" yet in the same newspaper, from Saturday July 4, to Tuesday July 7, 1713, the public was informed that "her majesty does not go to St. Paul's July 7, as she designed, but comes to St. James's (from Windsor) to return thanks to God for the blessings of peace."

If Handel's elaborate composition had been executed at St. Paul's, a style of music so new, forcible, and masterly, must have had a great effect on an English congregation, who had never heard ecclesiastical music so accompanied. Purcell's voice parts, always pleasing, well accented, and expressive, had little assistance from an instrumental band. Instrumental music, except organ playing, was but little cultivated in our country during his time. But Handel, besides his experience in Germany, had heard operas and masses performed by great bands in Italy, with such precision and effects, as were unknown in our country till he came hither to teach us.

Handel's *Te Deum* for the battle of Dettingen, 1743, and Graun's for the king of Prussia's victory at Colin, in 1757, are the most celebrated compositions to that sacred hymn of the last century, and the most likely to survive the present.

TEDIASTUM, in *Ancient Geography*, a town placed by Ptolemy in the interior of Liburnia, near Aruciz.

TEDJEN, or TEDYEN, in *Geography*. See TEDZEN.

TEDIF, a town of Syria, in the pachalic of Aleppo. Here is a Jewish synagogue; and the inhabitants have a tradition that one of the minor prophets resided here. On a hill near this town are some sepulchres and aqueducts cut in the rock; 21 miles E. of Aleppo.

TEDINGHAUSEN, a town of the duchy of Bremen; 9 miles S. of Otterberg.

TEDIUM, in *Ancient Geography*, a town of Arabia Deserta, near Mesopotamia. Ptol.

TEDLA, or TEDILA, in *Geography*, a province of the empire of Morocco, in the kingdom of Fez, which extends along the eastern side of Mount Atlas, and has to the west the province of Shavoya, and to the S. Morocco. This is a rich province, abounding in sheep, whose wool is so fine, that no silk is foster: it is used in the manufacture of caps worn by the opulent, and is sold at Fez at a very high price: its exportation being prohibited, it is consumed by the inhabitants. The province contains 450,000 inhabitants.

TEDNEST, or TEDOEST, a town of Africa, in the empire of Morocco. This town was destroyed by the Portuguese in the year 1514, and in part rebuilt by the Jews; 40 miles N.E. of Mogador.

TEDONG. See TIRUN.

TEDSI, a town of Africa, in the country of Sus, situated to the east of Tarudant; 90 miles S.W. of Morocco.

TEDZEN,

TEDZEN, a town of Persia, in Khorassan, on a river of the same name; 32 miles E. of Meshid.—Also, a river of Persia, in the province of Khorassan, supposed to be the ancient Ochus, and next in size to the Oxus. It has its source near Saraks; and after receiving many streams, and in the number Meshed river, falls into the Caspian sea, in N. lat. 38° 41'.

TEE, in the *Manege*. See **BREAST-Plate**.

TEE-Square. See **SQUARE**.

TEEBAKAN, in *Geography*, a small island in the East Indian sea, near the N. coast of Borneo. N. lat. 7° 52'. E. long. 117° 39'.

TEECHA, a town of Bengal; 45 miles E. of Calcutta.

TEEDIA, in *Botany*, so named by Perfoon, we know not with what meaning.—“*Perf. Syn.* v. 2. 166.” Brown in *Ait. Hort. Kew.* v. 4. 47. See **CAPRARIA**, sp. 3, *lusida*, on which alone this genus is founded, being distinguished by having a *berry* instead of a *capsule*, as is remarked in the place indicated. We have not had an opportunity of examining whether this be really the case, or whether it be a capsule with or without a pulpy coat; nor do we know how far Willdenow's suggestion, that all the Cape species possibly have a similar seed-vessel, is well founded.

TEEFEE, in *Geography*, a town of Africa, in Kaffon; 30 miles N.W. of Kooniakary.

TEEHEENGAN, a small island in the East Indian sea, N. of Borneo. N. lat. 7° 49'. E. long. 117° 30'.

TEEKOO, a small island in the Sooloo Archipelago. N. lat. 6° 6'. E. long. 120° 25'.

TEELNA, a town of Bengal; 10 miles W. of Conchong.

TEEMBIE, a town of Africa, in the country of Foota. N. lat. 10° 28'. W. long. 10° 48'.

TEEMBOO, a town of Africa, in the country of Foota. N. lat. 9° 59'. W. long. 10° 18'.

TEEN-TALLOW, a town of Hindoostan, in Guzerat; 20 miles S.E. of Brodera.

TEERAH, a province of Candahar, W. of Paisshawar.

TEERANDAZEE, a town of Candahar; 8 miles E. of Sussa.

TEERRAWHITTE, the south-west point of the northernmost island of New Zealand, in the South Pacific ocean, and the N. side of Cook's Straits.

TEERWISCH, a town of Prussia, in the province of Oberland; 8 miles N.N.W. of Ortelsburg.

TEES, a river of England, which rises on the borders of Cumberland, and runs into the German ocean, about ten miles below Stockton, N. lat. 54° 42'. The whole course forms a boundary between the counties of York and Durham.

TEESDALIA, in *Botany*, received that name from Mr. R. Brown, in memory of the late Mr. Robert Teesdale, F.L.S., who died on Christmas-day, 1804. This accurate English botanist was, for many years, a seedsman in the Strand, but retired from business some time before his death, residing first at Ranelagh, near Chelsea, and afterwards at Turnham-Green. He was the author of “*Plantæ Eboracenses*; or a Catalogue of the more rare Plants, which grow wild in the neighbourhood of Castle Howard, in the North Riding of Yorkshire, disposed according to the Linnæan System;” published in the *Transactions of the Linnæan Society*, v. 2. 103. The author composed this catalogue whilst he was gardener to the earl of Carlisle.—Brown in *Ait. Hort. Kew.* v. 4. 83. *Sm. Tr. of Linn. Soc.* v. 11. 283. *Compend. Fl. Brit.* ed. 2. 98.—Class and order, **TE-**
VOL. XXXV.

tradymania Siliculosa. Nat. Ord. *Siliquosæ*, Linn. *Cruciferae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of four elliptical, concave, small, spreading, equal, deciduous leaves. *Cor.* Petals four, obovate-oblong, obtuse, spreading, with short broad claws. *Stam.* Filaments six, slightly club-shaped, ascending, each with a dilated ovate scale attached to its inner side, a little above the base, the two lateral ones shortest and most distant, in one species wanting; anthers vertical, of two round lobes, distant at their base. *Pist.* Germen superior, sessile, roundish, emarginate, tumid at one side, flat at the other; style scarcely any; stigma capitate. *Peric.* Pouch erect, inversely heart-shaped, tumid, with a longitudinal furrow in front; concave, with an elevated ridge, at the back, two-celled; partition lanceolate; valves boat-shaped, oblique, keeled. *Seeds* two in each cell, ovate.

Ess. Ch. Pouch emarginate, inversely heart-shaped. Seeds two in each cell. Filaments with a scale on their inner side, near the base.

1. *T. nudicaulis*. Naked-stalked Teesdalia. *Ait. n.* 1. *Sm. Tr. of L. Soc.* v. 11. 286. (*Iberis nudicaulis*; Linn. *Sp. Pl.* 907. *It. Oeland.* 139. *Sm. Fl. Brit.* 692. *Engl. Bot. t.* 327. *Curt. Lond. fasc.* 6. t. 42. *Fl. Dan.* t. 323? *Burfa pastoris minima*; *Ger. Em.* 276. *Shepherd's Cress*; *Petiv. Herb. Brit.* t. 50. f. 2.)—Petals unequal.—Native of dry gravelly situations in the northern parts of Europe, flowering in April or May. It occurs about London, Norwich, and Bury, but is not a general English plant. The root is small, tapering, annual. *Herb* varying much in luxuriance and number of stalks. *Leaves* several, almost entirely radical, pinnatifid in a lyrate manner, stalked, roughish principally at the edges. *Stalks* unbranched; the central one always erect and naked; the rest ascending, spreading or decumbent, often bearing a leaf or two. *Flowers* white, very small, corymbose. *Calyx* smooth, often purplish. Two inner or upper petals as long as the calyx; outer ones full twice as long; all entire. The remarkable scales on the *stamens* were first particularly noticed in *English Botany*. On these Mr. Brown founds his principal generic character, omitting the irregularity of the petals, in which this plant agrees with *IBERIS*, though very little in its habit, which is rather that of a *LEPIDIUM*. (See those articles.) The writer of the present article has, in the *Transactions of the Linnæan Society* above quoted, critically investigated the history of this species and the following, and has first brought them together under one genus.

2. *T. regularis*. Regular-flowered Teesdalia. *Sm.* as above, 286. (*Lepidium nudicaule*; Linn. *Sp. Pl.* ed. 1. 643. ed. 2. 898. *Loefl. It. Hisp.* 155. *Nasturtium minimum verum*, *foliis tantum circa radicem*; *Magnol. Bot. Monsp.* 187. t. 186. *N. foliis pinnatifidis*, *caule nudo floribus tetrandris*; *Gerard Gallopr.* 347, excluding the *Iberis* of Linnæus.)—Petals equal. *Stamens* but four.—Native of dry elevated gravelly places in the south of France, and above the convent of St. Bernard at Madrid, flowering in the early spring. The root is annual. Whole herb so precisely resembling the foregoing, except in being usually rather less luxuriant, that it is scarcely possible to distinguish them, except by the flowers. The petals of the present are all of equal size, spreading, longer than the calyx. *Stamens* only four, two at each broad side of the germen, each bearing a white expanded scale, as in the *T. nudicaulis*; the two shorter, or more spreading *stamens* entirely wanting. It is much to be wished that seeds of this species could be procured from Montpellier, that we might compare both in a living state. Linnæus was always persuaded of their being distinct.

TEESE, in *Geography*, a town of Africa, in Kajaaga. N. lat. 14° 50'. W. long. 9° 27'.

TEESHOO LOOMBOO, or LUBRONG, a town and large monastery of Thibet, consisting of three or four hundred habitations of the Gylongs, besides temples, maufoles, and the palace of the sovereign pontiffs, all built of stone; 2 miles S.W. of Sgigatchee.

TEESTA, or Yo SANPOO, a river of Asia, which rises in Thibet, and runs into the Ganges by two streams, one 25 miles N., the other 80 E.S.E. of Moorshedabad.

TEETBADDY, a town of Bengal; 27 miles N.E. of Dacca.

TEETH, *Diseases of the*. The diseases which affect the teeth and the parts connected with them, are usually divided into two kinds; namely, into such as are termed *common*, because they are also met with in other parts; and into those which are called *proper*, being observed only in the teeth. Hence, as the celebrated Plenck has remarked, the subject may be conveniently treated of under the following heads. *Doctrinâ de Morb. Dentium, &c. Lovanii, 1796.*

Of Natural Dentition.—The process by which the teeth make their way through the gums, is named *dentition*, (see DENTITION,) which may be divided into the *first* and *second*.

1. *Of the First Dentition.*—In the sixth or seventh month after birth, the *first* or *milk* teeth make their appearance through the gums. The two middle incisors of the lower jaw are those which most frequently first come out, and, in the course of a few weeks, they are generally followed by the two middle incisor teeth of the upper jaw. At length, after some months more, the lateral incisors and the canine teeth shew themselves. The anterior molares, or front grinders, do not commonly pass through the gums until the child is a twelvemonth old.

The third and fourth grinders are cut about the tenth or twelfth year, and the dentes sapientiae at the age of twenty, or even at a more advanced period of life.

The *first* dentition, therefore, lasts from the sixth month to the second or third year. The *second* from the ninth to the thirteenth year.

But it is to be observed, that the interval betwixt the periods when the teeth are actually cut, is subject to very great variety, both with respect to different teeth and different children. Sometimes a month, sometimes half a year, and, on other occasions, a whole twelvemonth will elapse between the first appearance of one tooth and that of another.

The cutting of each tooth has two distinct stages; the first of which has been called the *periodus ingressus*; the second, the *periodus egressus*.

The first stage is usually observed in the fourth month, or about six weeks before the tooth passes through the gums. It happens when the tooth, in consequence of its augmented size, begins to press against the bony laminae of the socket, so as to make them recede. At this period the child feels a degree of itching in the gums, and hence it is that he now frequently puts into his mouth his fingers, or other hard bodies, and compresses them by strongly biting them between the gums. The secretion of the saliva is increased. The gums become red, and swell in the situation of the tooth which is about to be cut. When the child sucks, he irritates and bites the nipple; he is also commonly troubled with a purging and a cough; he is watchful, cries frequently, and becomes feverish.

Sometimes, however, dentition takes place so easily, that none of the preceding symptoms are remarked.

After a few days, the above complaints generally cease,

but not unfrequently come on again in about a fortnight or a month, that is to say, about the commencement of the second stage, or that in which the tooth makes its egress. Then the gum grows white, or exhibits whitish points in the situation of the tooth which is about to be cut. These are caused by the tooth itself, and disappear as soon as it has passed through the gum.

2. *Of the Second Dentition.*—In the seventh or eighth year, the milk-teeth, amounting in number to twenty, become loose, and gradually fall out, generally in the same order in which they were cut. Soon afterwards, the second or permanent teeth rise out of the gums. It hardly ever happens, that the second dentition produces any dangerous symptoms, the passage through the alveolar process and gum being now sufficiently capacious.

After the milk-teeth have spontaneously fallen out, or been extracted, they are almost always found to be destitute of fangs. This is a circumstance which has puzzled many eminent writers, and has even given birth to the erroneous doctrine, that the milk-teeth are never furnished with fangs. Suffice it here to say, that in the opinion of the best informed modern surgeons, the disappearance of the fangs is the effect of absorption.

Sometimes children, but more frequently adults, cut their teeth a third time. It is said that dentition has been observed to happen thrice in an infant five years of age; and Plenck was acquainted with a man, who was born with two of the grinding teeth, which were afterwards changed twice. (*Doctrinâ de Morbis Dentium, p. 10.*) Even a fourth dentition has been noticed by some very experienced men. Halleri, tom. viii. l. 30. p. 22.

Of Difficult Dentition.—The advance of the teeth out of the sockets or gums may be attended with the most alarming symptoms. But experience proves, that in numerous children, the whole semicircle of each jaw becomes furnished with teeth, without the slightest mark of indisposition either before, or during the progress of the teeth through the gums. In other instances the worst symptoms prevail, both while the teeth are making their way out of the sockets, and through the gums; such as an inflammatory swelling of the gums, tonsils, and parotid glands; redness of the eyes and cheeks; vomiting, griping pains, tenesmus, profuse diarrhoea with green evacuations, and sometimes obitinate costiveness and retention of urine. Fever, accompanied with cough and other catarrhal affections, hiccough, universal or partial tetanus, convulsions, &c. are the symptoms by which, according to the estimate of several writers, nearly a third of children are destroyed in difficult dentition.

These are the *common* symptoms of difficult dentition; but occasionally *peculiar* ones arise, which not unfrequently subside as soon as the tooth is cut; as, for instance, gutta serena (Lorry, *Traçt de Morb. Cutaneis, 1777, p. 411.*); deafness; amaurotic blindness; enlargement of the knees; paralysis; and lameness of one or both legs. (*Pasch, Abhandlung aus der Wundarzney von den Zahnen, S. 25. 36.*) Aphthæ of the mouth; an inflamed tubercle over the tooth which is about to be cut; suppuration, ulceration, and even sloughing of the gums. Rachitis is also alleged to have its origin sometimes from difficult dentition.

These effects are particularly met with in very plethoric and irritable children; or in infants whose bowels are overcharged with irritating excrementitious matter. Too much laxity, or too great hardness of the gums, is hardly ever the sole cause of such symptoms.

With regard to the prognosis, it may be remarked, that favourable dentition is a sign of future health. Ricketty children almost invariably cut their teeth with difficulty.

The

TEETH.

The more numerous the teeth are which are making their way out together, the more severe are generally the symptoms, and the greater is the danger.

Bloated, colic, heavy children are extremely liable to be carried off by dentition.

The incisors and grinders usually come out with more ease than the canine teeth. Thin children, who are affected with acute fever, and whose bowels are open, are in less danger from dentition. Infants who have a cough during this process, are often a long while in cutting their teeth. The foregoing prognosis accords with what was pronounced upon the subject by Hippocrates, whose accuracy remains unimpeached.

As the symptoms of dentition are partly *inflammatory*, being accompanied with a strong determination of blood towards the head and brain; and partly *spasmodic*, in consequence of the sympathy of the teeth with other parts, the treatment requires that antiphlogistic and antispasmodic means be employed. It is necessary, therefore,

1. That the bowels be kept open with emollient clysters.
2. That leeches be applied behind the ears.
3. That the syrup of poppies, with nitre and one or two drops of laudanum be internally administered.
4. That the red part of the gum over the tooth which is about to be cut, be rubbed with a mixture of lemon-juice and honey, or cream.
5. That in the event of there being a tendency to convulsions, in addition to the other symptoms, a division of the gum be made over the tooth. By the majority of practitioners, indeed, the last is considered as by far the most useful and efficient means of relief.

This incision is to be made through the gum with the common instrument, well known by the name of the gum-lancet, which is far better for the purpose than an ordinary lancet, which is apt to cut the tongue and lips, especially when the child moves about much. The grinding teeth require a crucial incision: all the others a simple transverse cut completely through the gum. The wound is then to be examined with the finger, in order to ascertain that no tenacious fibre over the tooth continues undivided. In this country, practitioners seldom apply any thing to the incision; but abroad, it is not uncommon to put to it a mixture of lemon-juice and honey.

Internally, antispasmodics may be exhibited, particularly the syrup of poppies, with the spiritus ammoniaci fucinatius.

In order to promote dentition, and render its effects on the constitution as mild as possible, the celebrated Plenck recommends, that as soon as the infant is five months old, its gums be rubbed several times a day with a mixture of lemon-juice and honey, first over the middle incisors of the lower jaw, and when these have come out, over those of the upper jaw.

Emollient remedies are said to relax the gums too much, the consequence of which is, that the loose gum is slowly and difficultly perforated by the tooth, as instead of ulcerating, it is only raised and rendered tense.

The use of hard applications, as biting the root of marsh-mallows, smooth corals, boars' tusks, &c. render the gums callous; but more good might, perhaps, be derived, if substances with rough surfaces were employed.

A premature incision of the gum soon closes again, and therefore does little service; but we do not believe that the cicatrix, thus produced, can be any impediment afterwards to dentition, as many have imagined; for it is an established fact, that cicatrices in general are more disposed to ulcerate and be absorbed, than the original parts of the body.

We would never suffer any idle apprehensions of the above sort to deter us from dividing the gum, were there any chance of benefit from the proceeding. At the same time, we do not recommend this as a prophylactic measure, but as being proper only when illness, suspected to arise from dentition, actually exists.

Premature Dentition.—This is stated to happen, when the milk-teeth come out before the infant is six months old. Sometimes children are even born with their teeth already cut. Rzacynky, Rhodius, P'Escluse, and Stoerck, mention a boy, who had the molars at the time of birth. Also in an abortion of six months, and another of seven, teeth have been observed. (Halleri Elementa Physiol. t. vi. p. 19.) Van Swieten met with two incisors in an abortion of five months. (Comm. t. iv. p. 742.) In a very weak male child, born at eight months, Arnold saw two perfect teeth rise out of the lower jaw on the seventh day after birth, and grow with extraordinary quickness; but they fell out in the eighth week from their first appearance. Obf. Physico-Med. p. 70.

In general it is to be concluded, that early dentition indicates great constitutional vigour and strength.

Of Backward Dentition.—Backward dentition is when the milk-teeth are not cut, though the child is a twelvemonth old, or even older. The proximate cause of this delay is generally referred by medical writers to languor and weakness of the constitution. But late dentition is of several kinds.

1. Backward dentition from an unknown cause sometimes happens, the teeth not making their appearance for a year after birth, notwithstanding the children have not any appearance of debility. Van Swieten met with a most healthy female child, who was nineteen months old when she cut the first tooth. Comm. t. iv. p. 742.

2. Backward dentition from the rickets. It is universally known, that in ricketty children the cutting of the teeth is a long while delayed. In these subjects the gums are always much relaxed, and we have already stated, that this circumstance is by no means favourable to dentition. It is probable, also, that in ricketty infants the teeth themselves are a long while before they are perfectly formed, it being well ascertained, that in such constitutions the deposition of the phosphate of lime takes place with extraordinary slowness and difficulty.

3. Backward dentition of the dentes sapientia. The wise teeth are seldom cut before the twentieth year, and sometimes they first come out in persons considerably advanced in years. Halleri Element. Physiol. t. vi. p. 28.

4. Late dentition in adults. Sometimes this takes place a third time, chiefly with respect to the incisors; and instances are actually recorded, in which these teeth were cut in adults, or even in old persons. Haller quotes examples, in which they were cut at the ages of 90, 95, 100, 118, 120, and later. Halleri, l. c. t. viii. l. 30.

Wrong Situation of the Teeth.—This happens when the teeth make their appearance in the palate, or in any place not comprised in the alveolar arches. The proximate cause of this unpleasant occurrence is the preternatural formation of the young tooth in an erroneous situation.

The cases may be of different kinds, in regard to the place which the tooth occupies.

1. When a tooth grows out of the palate, it obstructs mastication, and by rubbing against the tongue, often makes it ulcerate. The inconvenience can only be remedied by extracting the displaced tooth.

2. The tooth may come out under the tongue. This case produces the same grievances as the preceding, and requires the same mode of relief.

TEETH.

3. The next curious circumstance which we have to notice, is the growth of teeth in the ovaries. It is now believed, that the teeth sometimes found in these organs, are not always the relics of a previous embryo, but may be formed there as a *lufus naturæ*. An instance, in which a tooth was formed in an encysted swelling in the orbit, has been lately recorded by Mr. Barnes of Exeter. See *Medico-Chir. Transf.*

4. Albinus records an example, in which a tooth grew out of the maxillary process below the orbit. It was concealed until it made its way out in this extraordinary situation. *Annot. Acad. t. i. p. 54.*

5. The teeth have sometimes been observed inverted, their bodies being situated towards the jaw. *Pollich, Increm. Ossium, p. 25. Albin. c. 9. Palfin, c. 9.*

Extraordinary Distance of the Teeth from each other.—Sometimes the teeth are placed too distant apart, so that between their crowns large interspaces are left.

1. In children three years of age, the crowns of the milk-teeth are so close to each other, that they are laterally as it were in contact; but in children seven years old, there are wide interspaces between them. The reason of this is owing to the jaw increasing in size, while the dimensions of the teeth undergo no alteration. The second or permanent teeth, on the other hand, (at least the first twenty of them,) have larger bodies than the milk-set.

2. Frequently the tartar insinuates itself between the crowns of the teeth, and occasions a considerable separation of them. We need scarcely observe, that the cure requires that the tartar should be taken off, and the teeth reduced into their natural position.

3. The deformity of which we are now treating, is occasionally ascribable in adult subjects to the preternatural breadth of the jaw, in which circumstance it is absolutely incurable.

Extraordinary Closeness of the Teeth.—The teeth may be too crowded together, so that their crowns are laterally in contact. This defect may extend to some or all the teeth. The frequent consequence is, that the lateral margins of these parts become carious.

There are two species of the disorder.

1. The first arises from the great width of the crowns of the teeth, and it may be ascertained by ocular examination. In some instances, all the bodies of the teeth are preternaturally wide; in others, only a certain number of them.

The mode of cure consists in filing off a little of the lateral edges of the teeth affected.

2. The second species is caused by the uncommon shortness of the jaw. It may be known by observing that the crowns of the teeth are not too large, and that the alveolar arches are strikingly diminutive.

Here the mode of relief is the same as in the foregoing case.

Extraordinary Number of Teeth.—Sometimes the number of the teeth exceeds what is the usual share of the human species in general; and this particularly occurs whenever the number amounts to more than thirty-two. Columbus has seen thirty-three (p. 34.); Fauchart, thirty-three and thirty-four (edit. 2. tom. i. p. 3.); Bourdet, thirty-six (p. 25.); and Ingrassias, thirty-six, including twenty-four grinders. *Text 2.*

1. With respect to the redundant number of each class, it is when there are six incisives, or four canine teeth, or more than ten molares in one jaw. The case is incurable.

2. In some instances, the excessive number is owing to there being a double row of teeth. This malformation may happen to both jaws, or be confined to one. It has been

noticed in both jaws by Munick, p. 144; Plinius, c. xi. p. 623; C. Bartholinus, p. 464, &c.

Arnold met with a boy, fourteen years old, who had altogether seventy-two teeth in his mouth. There was a double set of the incisives, canine teeth, and three posterior grinders; but the anterior grinders were triple: consequently there were counted in each jaw eight incisives, two canine on each side, and twelve molares. The incisives were not arranged in an even double row, but each row seemed irregular, and its order as it were promiscuous. The arrangement of the canine and grinding teeth was more regular. None of these teeth were affected with caries. *Obs. Physf. Med. p. 69.*

3. There may be a larger number of teeth than common, in consequence of the presence of one of the milk-teeth; for when the latter does not fall out at the usual period, the corresponding permanent teeth come out in the vicinity of it.

Here the cure consists in drawing the superfluous milk-tooth.

Deficient Number of Teeth.—Sometimes the number of the teeth falls short of what is usual; and this happens whenever they are fewer in the adult subject than thirty-two.

1. The defective number may be owing to a preternatural shortness of the jaw. Sometimes one or more teeth remain concealed during life. Thus, the *dentis sapientie* are never cut in persons who have the upper or lower alveolar arch not sufficiently long.

2. The sex also makes a difference; women, generally speaking, having fewer teeth, than belong to men. *Riolan, p. 38, and 39.*

3. The deficiency in the number may proceed from a tooth having been drawn, or dropped out. This is evidently a case which can only be remedied by the insertion of an artificial tooth.

4. Lastly, the limitation of the number may be owing to infancy; for, in children under seven years of age, the natural number of the teeth does not exceed twenty.

Obliquity of the Teeth.—The position of some or all the teeth may be oblique; an inconvenience which may be caused by the milk-teeth not being shed, by tartar insinuating itself into the interspaces of the teeth, by looseness of the alveoli, and, lastly, by a forcible luxation of the teeth affected. The milk-teeth seldom grow obliquely; the permanent ones do so much more frequently. The molares hardly ever rise in a wrong direction; and, in general, they are only the incisives and canine teeth which deviate from the right position.

With regard to the effects of such obliquity, we have to observe, that the teeth affected impede mastication, interfere with the articulation of words, seriously disfigure the countenance, and, unless drawn, or replaced in their natural position, may occasion incurable ulcers on the tongue, lips, or cheeks.

The differences of the obliquity make these cases divisible into several kinds.

1. The obliquity forward is when the tooth projects anteriorly, so as to hurt the cheek or lips. Such a tooth may cause ulceration of these parts, as already mentioned. The parotid duct has been known to be perforated, and a salivary fistula brought on, by an oblique tooth in the upper jaw. *Paseh, l. c. p. 71.*

2. The obliquity backward is when the position of the tooth inclines towards the centre or posterior part of the mouth, so as to be capable of hurting the tongue. Teeth, so circumstanced, have sometimes been the cause of ulcers on the tongue, which in point of obstinacy and malignancy have truly vied with cancer. *Plenck* informs us, that by draw-

TEETH.

ing the left eye-tooth, he once cured an ulcer, which had existed half a year on the left edge of the tongue. P. 20.

3. The converging obliquity is when the crowns of the teeth converge in their situation, or even cross each other.

4. The diverging obliquity is when they diverge.

5. The lateral obliquity is when the side of the body of the tooth is turned more or less forwards or backwards.

6. Obliquity of the fang. Sometimes the fangs of the teeth are curved so obliquely backwards or forwards, that the bottom of the sockets either projects like a small exostosis, or is completely perforated.

Of the Reduction of an oblique Tooth.—With respect to one of the permanent teeth, which is rendered oblique by the presence of one of the first set, the treatment consists in immediately extracting the latter.

The milk-tooth may be known by its pearl colour, its more polished surface, and its smaller size. The permanent tooth is longer, whiter, stronger, and of greater breadth. The crowns only of the second set of grinders are shorter than those of the milk-set. Albini, Annot. Acad. l. ii. p. 19.

But an oblique permanent tooth may be replaced in its right position, by the following means.

1. When the child is very young, and the tooth quite recent, it may be reduced into its proper situation, by frequently pressing upon it with the finger in the course of the day.

2. Or the reduction may be effected with a double silk-thread, smeared with wax and mastic. A noose is to be made at each end of the thread, and fastened to the adjacent teeth. The thread, being then divided into two, is to be made to cross two or three times firmly over the oblique tooth.

3. By a metallic plate. The length of the plate should exceed the measure of the two neighbouring teeth, together with the oblique one. Its width should be less than the height of the teeth. It is to be applied to the inside of such teeth as incline inwards, and to the outsides of those which incline outwards. At the ends of the plate are two holes, through which the silk-threads, smeared with wax, are to be passed, and, after crossing each other, are to be tied over the oblique tooth.

4. By Bruner's machine. When the tooth does not admit of reduction by the preceding means, Bruner's machine may be tried. See A Bruneri Einleitung zur Wissenschaft eines Zahnarztes, p. 83.

When several of the teeth are oblique, the cure is to be attempted by the same operations; but when the side of a tooth inclines forward, it is necessary to use the forceps to bring the part into its right position.

Looseness of the Teeth.—Sometimes the teeth become loose and moveable in their sockets. The proximate cause of this affection may depend upon the loss of the elasticity of the alveoli and gums, upon the too great or too small size of the sockets, or upon the absorption or wasting of the fangs. Loose teeth are very inconvenient in mastication, and easily drop out.

Of this complaint there are several species, the differences of which are referrible to the causes.

1. Looseness of the teeth from second dentition. After the seventh year, the twenty milk-teeth begin to grow loose, and fall out, nearly in the same order in which they were cut.

2. Looseness of the teeth from age. In old persons the sockets become contracted, and the canal in the fangs being obliterated, these parts also diminish. Hence we see the reason why the teeth frequently become loose in subjects advanced in life.

3. Looseness of the teeth from violent concussions. A forcible concussion, such as happens in falls against the teeth, diminishes the elasticity of the gums and sockets, and of course may be a cause of the present disorder.

The cure requires corroborant washes: the tinctura laccæ, astringent decoctions, red wine, spirit of wine, or the terra catechu or sanguis draconis, dissolved in camphorated spirit.

4. Looseness of the teeth from relaxation of the gums. There are people whose gums are pale and relaxed, at the same time that there is no appearance of scurvy.

Here the cure is to be accomplished by the means recommended for the preceding case.

5. Looseness of the teeth either from caries of the socket or fang. This case may be known by the emission of pus from the socket of the loose tooth. Sometimes a cure may be effected by gargles; but, in general, if the tooth is also painful, it ought to be extracted.

6. Looseness of the teeth from scurvy of the gums. In subjects with scurvy, the gums become loose and fungous, and the sockets filled with a fetid purulent matter: hence the teeth are loosened.

The cure requires the internal exhibition of antiscorbutic medicines, and the use of antiscorbutic washes.

7. Looseness of the teeth from mercury. Mercury acts specifically upon the gums, destroying their tone, and promoting the secretion of saliva. Hence, persons using mercury, either outwardly or inwardly, are liable to have their teeth rendered loose.

The cure demands purgative medicines, the expulsion of the mercury from the system, and the use of tonic gargles.

Defect of Teeth.—When the teeth are entirely wanting, several very unpleasant effects are necessarily the consequence. The proper mastication of the food being then absolutely impossible, cardialgia, and other complaints connected with difficult digestion, are produced. The deficiency of the grinding teeth occasions a collapse of the cheeks, and of course an unflattering emaciation of the countenance; while the want of the incisores spoils the voice.

1. It is natural for all young infants to be without teeth, until they are seven or eight months old; but when the teeth do not begin to come through the gums after a child is a twelvemonth old, then the backwardness of dentition may be considered as morbid.

2. In old persons, the teeth naturally fall out, and the alveoli contract into a kind of sharp edge, covered with the callous membrane of the gums, by which the softer species of food may yet be chewed.

3. Want of teeth from rickets. When the rudiments of the permanent teeth are destroyed with the milk-teeth, then of course no secondary teeth ever make their appearance.

4. Loss of teeth from violent causes. Under this head we comprehend the defect of one or several teeth, drawn, or beaten out.

5. Loss of teeth from necrosis. Every form of this disorder makes the teeth fall out in little pieces.

6. Loss of teeth from scurvy. In situations where the scurvy is prevalent, it is common to meet with numerous persons who have lost their teeth in the very prime of life.

Every kind of deficiency of teeth, except that which belongs to infancy, cannot be remedied in any other way but by the insertion either of artificial or natural teeth.

Of the Insertion of Teeth.—There are various species of this operation, but all of which may be included under the following heads.

1. The insertion of a healthy proper tooth. When a tooth that has been extracted, or beaten out, appears to be entirely sound, it is to be immediately replaced in the socket, and tied with thread to the adjacent teeth. Sometimes it spon-

spontaneously becomes fixed again, if care be taken to use an astringent gargle with a view of making the gum contract.

2. The insertion of a proper tooth that has a carious fang. When the tooth, which has been removed from the alveoli, is merely carious in the fang, it may be replaced again, after the carious part has been filed away.

3. The insertion of a proper tooth, which has a caries of its body or crown. When a very small portion of the crown is carious, it may be removed with a file, and the tooth can then be put into its socket again. But if the whole body be diseased, it may be cut off transversely from the root; a small hole may be drilled across the latter part, and, with the help of a golden wire, an artificial crown or body, having also a transverse hole for the passage of the wire, may be fastened to the root. In this state, the tooth may be replaced.

4. The insertion of a tooth taken from the mouth of another living subject, or from a dead subject. The person, to whom the tooth is to be transferred, should not be above the age of forty; but the subject, from whom it is to be taken, ought not to be more than four-and-twenty. The transplanted tooth should belong to the same jaw and side of the face, and be of the same shape and size, as the tooth that is extracted.

The canal of the tooth, which is to be inserted, must be closed with gold; and the tooth must be every where rendered free from inequalities, so that it may be the more likely to adhere.

5. The insertion of an artificial tooth. The form and size which should be given to the artificial tooth must be determined by a model of soft red wax, which has been pressed into the gap made by the lost tooth. In order that the white colour of the artificial tooth may correspond to the light yellowish colour of the rest of the teeth, the new tooth should be macerated in strong coffee, or in the lees of red wine.

Artificial teeth ought to be made of ivory, or of the tooth of the hippopotamus. Each of them should be grooved on both sides, and perforated transversely, so as to admit of being tied to the neighbouring teeth. The nooses of two threads are to be fastened on the neighbouring teeth, and the ends having been drawn transversely through the hole of the artificial tooth, and there made to decussate, they are to be tied in a surgeon's knot. The tooth having been placed in the socket, the threads betwixt the artificial and old teeth must be tightened and made fast. Lastly, an astringent gargle must be used for a few days.

6. The insertion of several artificial teeth. When two, three, or a larger number of contiguous teeth are wanting, an equal number must be formed of one piece of ivory, or other substance, and fastened at once to the neighbouring teeth.

7. The insertion of a whole set of artificial teeth. When all the teeth of the upper and lower jaws are lost, a complete set may be fixed on the margins of the alveolar arches. Should any of the natural teeth remain, they may often be of great assistance, in rendering the lodgment of the artificial ones more firm and secure. When the whole, or the greater part, of the teeth of either jaw is lost, an artificial set may also be inserted.

The custom of wearing ivory teeth, and of binding them in with a gold wire, is very ancient: Lucian and Martial speak of it as practised among the Romans. But ligatures of wire have been found to hurt the natural teeth, with which the artificial are connected; whereas silken twill cannot affect them to any considerable degree for several years.

Guilleman gives us the composition of a paste for making artificial teeth, which will never grow yellow: the composition is white wax granulated, and melted with a little gum elemi, adding powder of white mallich, coral, and pearl.

Thus whole sets may be made for one or both jaws, so well fitted to admit of the necessary motions, and so conveniently retained in their proper situation, by means of springs, that they will answer every purpose of natural teeth, and may be taken out, cleaned, and replaced by the patient himself with great ease.

Wearing out of the Enamel.—(See CRANIUM.) The bodies of the grinding teeth being wide, excessively hard, and exposed to perpetual friction, they become worn much sooner than the rest of the teeth, and flat in consequence of the destruction of their points. Halleri Element. Physiol. t. vi. p. 29.

With respect to the effects of the loss of the enamel, it is to be observed, that the teeth which are deprived of it become so sensible, that painful sensations are produced in them by heat and cold, and by solid as well as liquid aliment. In the end, also, they readily become carious.

The species of this affection depend upon the causes.

1. Loss of the enamel from age. After the age of thirty, almost all the teeth in the human subject have been somewhat worn by long mastication. Some writers assert, that in youth, the waste of the enamel may be repaired by nature; but if the teeth be destitute of vascularity, the evil must be always irreparable. See CRANIUM.

2. Loss of the enamel from gnashing of the teeth. Persons who in the night are in the habit of gnashing their teeth destroy the enamel. For the purpose of preventing the ill consequences of this practice, it has even been recommended to cover the teeth in the night-time with a thin gold plate.

3. Destruction of the enamel by the use of tobacco-pipes. Plenck informs us, that in the incisor teeth of men, who had for many years been accustomed to smoke pipes, he has seen the distinct impression of a black semicircle.

4. Loss of the enamel from long and violent brushing of the teeth. They who daily rub and brush their teeth forcibly with a rough hard tooth-powder, or too stiff a brush, inevitably destroy, in the course of a few years, all the enamel on the front surface of the teeth. Here the cure obviously depends upon the avoidance of the cause.

5. Loss of the enamel from applying the file to the teeth. Whenever this operation is carried to too considerable a depth, the enamel is removed by mechanical violence.

6. Loss of the enamel from biting a very hard body. This sort of violence sometimes splits the enamel, which immediately falls off in pieces, at the very time of making the bite.

7. Loss of the enamel from its being preternaturally brittle. When the enamel is thus affected, it is apt to break in chewing and biting substances without the exertion of any particular degree of force.

8. Loss of the enamel from the projection of an opposite tooth. A tooth which juts out considerably, so wears the corresponding tooth in the opposite jaw, as to make a deep impression in it. The treatment consists in shortening the tooth, which is injurious on account of its length, with a file.

Concretion of several of the Teeth into one Mass.—A true ankylosis of the teeth cannot happen from any process like ossification, because they possess no vascularity; and some of the cases, referred to by writers, were probably original malformation.

There are several varieties specified.

TEETH.

1. The true concretion of the teeth, which happens when the teeth are connected together by a substance resembling bone.

2. The spurious concretion, or that arising from the excessive closeness of the teeth to each other, in which state they seem as if they had actually grown together.

3. The concretion from tartar. Sometimes the interspaces of the teeth are so filled up with tartar, that the teeth cohere in such a degree, as to cause an appearance resembling what may be supposed to proceed from an actual bony concretion of those bodies. The mode of treating this case will be considered in speaking of the tartar of the teeth.

4. The close contact of the fang of the tooth with the socket. In this circumstance, the tooth either cannot be extracted, or, in the event of great force being used, the tooth is broken away from the jaw.

Elongation of the Teeth.—Sometimes one or more of the teeth appear to become longer.

1. Elongation of a tooth from the deficiency of the opposite one. Thus, when one of the molares of the upper jaw is drawn out, the corresponding tooth of the lower jaw seems lengthened; because after a time the neighbouring teeth are worn down by the friction which they continually exercise against each other.

2. Elongation from preternatural softness of the tooth. Plenck informs us, that he has seen in a female child eight years old, the right canine tooth of the lower jaw elongated, and which, after being extracted, was found so soft, that the crown and fang could be compressed with the finger.

3. Elongation of a tooth from excessive growth is mentioned by writers; but this case cannot be possible, as the teeth are known not to be vascular.

4. Imaginary elongation. Persons whose teeth are affected with stupor, are apt to fancy that their teeth are longer than natural; but without real cause. The cure consists in removing the stupor.

Foulness of the Teeth.—The teeth are often seen covered with a fœtid, fetid, yellowish, or dark-brown mucus.

The proximate cause is the adhesion of the mucus of the mouth and fauces to the surface of the teeth.

1. Morning foulness. In almost all men, the teeth become coated in the night during sleep with a dirty mucus, and appear foul in the morning. The reason is, because during sleep the saliva is more slowly secreted in the mouth; and, on account of the motionless state of the tongue and jaws, it is not washed off the teeth.

This species of foulness is easily removed by washing the mouth every day with cold water, and the teeth with a bit of rag, the finger, or a wet sponge.

2. Foulness of the teeth from neglect to clean them. They who are not in the daily habit of washing their mouths and teeth with cold water, by degrees have the interstices and fangs of their teeth incruited with mucus in the morning, and with the remaining particles of the food.

With respect to the treatment, merely washing the mouth in this instance is not enough; it is also requisite to clean the teeth occasionally with tooth-powder.

3. Foulness of the teeth from fever. This is remarkably seen in cases of putrid fever, in which, owing to the state of the saliva, the teeth become covered with a yellow or dark-brown coat.

Here the teeth should be frequently washed and cleaned with vinegar.

4. Foulness from ptyalism, especially that produced by mercury. In the beginning of a salivation, the teeth become coated with mucus. The best treatment is to wash and clean them frequently with a honey gargle.

5. Scorbutic foulness. In persons labouring under scurvy, the teeth are invariably covered with a purulent kind of mucus, issuing from the sockets of the loosened fangs.

The cure demands the internal and external employment of anti-scorbutic remedies.

6. Foulness of the teeth from tartar. In the early state of the formation of tartar, the surface of the teeth becomes covered with a mixture of earth and gluten.

The treatment consists in removing the tartar with a thick tooth-powder.

Of cleaning the Teeth.—In persons whose teeth are perfectly sound, it is only necessary to wash their mouths every morning with water that has had the chill taken off it, and that contains a few drops of the spirit of lavender; the mucus being wiped from the teeth with a bit of rag, or sponge. The same should also be done after meals, and the fragments of meat lodged between the teeth must be removed with a tooth-pick, which instrument some recommend to be made of juniper wood.

But in persons in whom a deposition of tartar readily takes place, the tartar ought to be removed with a tooth-scraper, and the teeth well cleaned every week with tooth-powder.

Charcoal, or carbon, is used for cleaning the teeth, and the best is made from the shell of the cocoa-nut. We are informed by historians that the ladies among the ancient Britons used the charcoal made with the wood of the common hazel-nut for this purpose. See DENTIFRICE.

The absorbent earths are used for dentifrices; they mechanically cleanse the teeth from the thick mucus and tartar, and at the same time preserve the tone of the gums. Therefore,

1. The basis of dentifrice powders may be prepared shells, red corals, mother-of-pearl, powdered crabs' claws, bone of the cuttle-fish, lapis hæmatites, &c.

2. For communicating an agreeable colour to the powder, carmine or cochineal may be added.

3. For giving an agreeable odour, ambergris, cinnamon, or cloves may be used.

4. For strengthening the gums, armenian bole, sanguis draconis, or terra catechu, is the best ingredient.

Rough tooth-powders, like that containing pumice-stone, gradually wear away the enamel, especially when they are employed every day.

Acid applications, particularly the mineral ones, do indeed whiten the teeth; but when long used, render them brittle.

Hence crude and burnt alum ought to be rejected from every kind of dentifrice. The nitric, muriatic, and sulphuric acids in tinctures are still more hurtful.

Of the Tartar of the Teeth.—This substance is an earthy crust, which adheres to the teeth. As it fills up the interstices of several of the teeth, and occupies their external surfaces, it is seldom observed upon their insides. By the Greeks it was called *odontolithos*, from *ὄδους*, a tooth, and *λίθος*, a stone. By others it has been termed *tophus*, vel *calculus dentium*.

With regard to the effects of the tartar, it displaces the teeth, and renders them loose and painful; it also separates the gums from the fangs, producing caries in the latter, and a bad smell in the breath.

In respect to colour, the tartar of the teeth is of three kinds, namely, dark-brown, yellow, and black.

Since many persons who never clean their teeth at all are not disfigured with these depositions of tartar, it appears that a peculiar disposing cause is necessary for the occurrence of the complaint. The species are:

TEETH.

1. Tartar from neglect to wash the mouth. It originates from the gluten of the saliva, which, in uncleanly scorbutic subjects, and great wine-drinkers, adheres to the teeth, becomes putrid with the heat, and in putrefying deposits a sort of earthy matter upon the teeth. People who drink chiefly water are seldom troubled with earthy incrustations on their teeth.

The cure requires the removal of the tartar. Small portions of tartar may be taken off by means of a brush and a thickish tooth-powder.

But when the tartar is abundant, thick, and grown, as it were, to the teeth, it must be cut with a suitable instrument placed obliquely, beginning from the neck, and carrying the instrument towards the upper part of the tooth. The tartar having been cut, is then to be removed piecemeal.

Any remaining particles of tartar may afterwards be gradually got rid of by the use of a brush and tooth-powder.

2. Spontaneous tartar. There are certain persons, whose teeth are constantly incrustated with tartar, notwithstanding they are in the continual habit of washing their teeth and mouths.

This peculiar diathesis seems to consist in an extraordinary quantity of earthy matter in the saliva.

Berdmore relates a surprising example of this sort of tartar. A man, thirty-two years of age, had the teeth of each jaw coated with solid tartar, half an inch in thickness, both on the outside and inside of the teeth, and on the surface of the gums, so that the interstices of the teeth were altogether invisible. The gums were every where pushed off the teeth, and painful. The incrustations upon the incisor teeth were so thick, that the lower lip was rendered more prominent. During a fortnight, Berdmore removed every day some of the tartar from the teeth with an instrument, and at length employed a dentifrice and brush. The retracted gums were scarified, and thus made to adhere to the necks of the teeth. The patient was obliged to brush his gums and teeth three times a day, partly with a view of preventing the new formation of tartar, and partly in order that the regeneration of the gums might be still more promoted. But although the patient strictly followed this plan, his teeth and gums, in the course of half a year, became again covered with an extremely thick coat of tartar. Berdmore was therefore under the necessity of recommending the use of a stiffer brush, and a dentifrice made of shells, for the purpose of removing the tartar. P. 56.

With respect to the treatment of tartareous incrustations of the teeth in general, it is essential to remove the tartar and clean the teeth well every day.

The internal and external remedies also, which are usually advised for dissolving stones in the bladder, may be employed, as lime-water, pure potassa, &c.

Sometimes peppermint-water, with a few drops of nitrous acid, is used with advantage.

3. Tartar from the porosity of the surface of the teeth. Persons who are in the habit of using acid tinctures or powders which dissolve the enamel, and make it porous, are frequently troubled with tartareous incrustations.

The cause being avoided, the mode of treatment is the same as in the preceding cases.

Of Blackness or Necrosis of the Teeth.—This is a very peculiar affection of all the teeth, making them appear black, rough, and eroded.

Sometimes only the upper part of the crown exhibits a dark-coloured rosion; while, in other instances, the whole substance of the tooth is eroded.

The proximate cause of this disease is imputed by Plenck to injury of the nutrient vessels of the pulp by disease, before

the growth of the tooth is thoroughly completed; and, therefore, it is a totally different disorder from necrosis of the bones, which is attended with phenomena, connected with the vascularity of the parts themselves.

Hence it is only in infants that several of the teeth are usually thus distempored.

Necrosis of the milk-teeth is indeed much more frequent than of the permanent set.

The following varieties of the complaint, depending on the difference of the cause, have been distinguished.

1. Blackness of the teeth from rachitis. In ricketty infants, the milk-teeth come out of the jaw more tardily, and they soon afterwards turn black and friable, and fall out piecemeal. The secondary teeth also, when rachitis is not cured between the first and second dentition, are affected with the same destructive change, so that subjects of this description are either destitute of teeth during the whole of their lives, or only have in their mouths teeth which have a black eroded appearance.

As for the cure of rachitis, we do not intend to consider it in the present place, and shall merely state that the pure milk of a healthy nurse, salubrious air, a great deal of exercise, good food, absorbent medicines, white alkaline salts, bark, steel, sea-bathing, &c. are the remedies principally recommended.

2. Scorbutic blackness of the teeth. When the scurvy attacks children before the ossification of the teeth is completed, the milk-teeth, as soon as cut, either appear to be already eroded, or in a short time afterwards become so, and put on a black colour.

The cure demands the immediate exhibition of anti-scorbutic medicines, with the assistance of which the second teeth are sometimes perfectly healthy.

3. Blackness of the teeth from the small-pox. In children who are seized with malignant small-pox during the first or second dentition, a black erosion of the teeth is frequently observed.

The cure requires the repeated administration of purgatives, and then the Peruvian bark.

4. Blackness of the teeth from measles. The same black erosion of the teeth has been remarked after severe cases of measles.

The cure is the same as in the foregoing instance.

All the preceding species of necrosis, when they affect the milk-teeth, are to be stopped by their proper specific remedies, in order that the second set of teeth may not be affected; but when these are disordered, the case is irremediable.

5. Blackness of the teeth from tartar. The tartar itself sometimes turns black, and even after its removal, the teeth often remain of a blackish colour, which cannot be effaced.

6. Blackness of the teeth from the application of mineral acids. Nitrous acid diluted with water, in a short time, whitens the teeth; but soon afterwards renders them black and friable. Plenck has seen the lateral edges of the teeth turned black and corroded by the employment of mercurial cosmetics.

7. Blackness of the teeth from cancer. Plenck has twice noticed in men, who were afflicted with ulcerated cancers of the lower lip, the teeth disfigured with a deep black colour. But it is to be remarked, that the affection was confined to the enamel, and did not extend to the bony substance of the fangs.

Preternatural Colour of the Teeth.—This is a change of the natural colour of the teeth to a yellow or ash-colour.

1. Discolouration from neglect to clean the teeth. The

fordes,

TEETH.

fordes, which collect upon the teeth, diminish their gloss and whiteness, and render them yellow or ash-coloured.

The cure consists in removing the fordes.

2. Discolouration from age. The whiteness and polish of the teeth, peculiar to youth, change in the advanced period of life into a dull yellow, which is totally irremediable.

3. Discolouration from the use of mercury. The teeth are discoloured not only by the internal, but also by the external use of mercury. Hence gilders, and other artizans who make use of mercury, have their teeth stained of a leaden colour. Plenck has seen the same sort of disfigurement occasioned by cosmetics containing quicksilver.

The cure requires that the mercury be got out of the system as expeditiously as possible.

4. Discolouration from scurvy, &c. Scorbutic persons are especially noticed as having the colour of the teeth spoiled. Venereal and ricketty subjects are also frequently affected in the same way.

To this head must likewise be referred the discolouration of the teeth observable in mariners.

5. Discolouration of the teeth from pregnancy. In pregnant and suckling women, the lustre of the teeth is often remarked to lessen, and these parts to be discoloured. Lorry, *Traçt. de Morb. Cutaneis*, p. 61.

It is supposed that this change of the teeth is frequently connected with the bad state of the milk, the evacuation and correction of which are the means of cure advised by several authors.

6. Discolouration from taking hot food. Persons who make a practice of drinking very hot liquids, or of chewing substances which are too warm, have the lustre and whiteness of their teeth destroyed. It is questionable, whether the beautiful white colour of the teeth of animals in general may not be owing to their abstaining from hot aliments?

7. Discolouration from dentifrice powders and sinctures containing mineral acids. Thus, burnt alum and spirit of nitre for a short time whiten the teeth; but a little while afterwards, the enamel turns pale and falls off in bits.

8. Discolouration from the smoke of tobacco. The oil of this plant is well known to have the effect of turning the colour of the teeth to a dark brown or black.

9. Discolouration from thinness of the enamel. When the vitreous substance is in a certain degree worn away, the bony substance, which is yellow, can be seen through it. The defect is incurable.

10. Discolouration from an internal caries of the tooth. Such a tooth loses its lustre and whiteness, and becomes pale, ash-coloured, dark-brown, and at length black.

Here the only mode of cure is to extract the diseased tooth.

11. Discolouration from the use of madder. It is remarked, that only the bony part of the tooth is stained red by this root, but not the enamel. The redness also does not extend itself to the portion of the tooth already formed; but only to the part formed while the animal is fed with madder. This colour likewise never disappears: circumstances much against the doctrine of the teeth being vascular.

12. Golden discolouration of the teeth. This species is brought on by art.

Fragility of the Teeth.—In this affection, the cohesion of the substance of the teeth is so slight, that a very inconsiderable force makes it break.

The proximate cause of this fragility of the teeth is probably connected, in many examples, with some imperfections in their original growth.

The varieties described by writers are as follow:

VOL. XXXV.

1. The scorbutic fragility. In people afflicted with the scurvy, the bodies of the teeth by degrees become so fragile that they drop out piecemeal.

2. Fragility from rickets. In children thus affected, the milk-teeth, soon after they have been cut, become dark-coloured, are easily broken, and usually fall out in pieces.

3. Fragility from old age. In old age the teeth are apt to be broken in biting with force, and to fall out piecemeal.

4. Fragility from the application of mineral acids or burning oils. The abuse of such medicines, too long continued, brings on a species of fragility, which admits of no mode of cure.

5. Fragility from caries. Teeth, which are excavated by caries, and rendered thin, are readily broken in mastication, and drop out in pieces.

All the different species of fragility are incurable.

Mollities, or Preternatural Softness of the Teeth.—This disease is so remarkable a softness of the substance of the teeth, that it can almost be compressed together by the fingers.

The proximate cause is said to be either too great a quantity of the gluten, which connects the earthy particles together, or else a deficiency of the earth.

The species are:

1. Softness of a milk-tooth. Plenck extracted from a girl seven years of age, a canine milk-tooth of the lower jaw, which was livid and soft, like cartilage, and was compressible by the fingers, especially at the fang. *De Morb. Dentium*, p. 39.

2. Softness of the teeth from sarcoctosis of the fang. Sometimes the fang of a tooth is absorbed, and a fungous substance fills up its place. This case has been absurdly instanced as a specimen of mollities of the teeth.

3. Softness of the teeth from scurvy. It is asserted, that in the scurvy, the teeth have been sometimes softened and enlarged. (*Grainger Hist. Febris Anom.* p. 6.) But such accounts must be incorrect, since they imply a vascular organization of the teeth. It merits attention also, that in certain dead subjects, whose bones are all affected with mollities, the teeth are found perfectly hard.

Preternatural Angles, or Sharpness of the Teeth.—Sometimes the form of a tooth is so acute, that it hurts the neighbouring parts by pricking them.

The effects of such a tooth are irritation of the tongue, or of the inner surface of the lips, or cheek. Hence inflammation of these parts, or an ill-conditioned ulcer opposite the sharp portion of the tooth, curable by no means whatsoever, except the removal of the angle or sharpness.

The species are ascribable to the particularity of the cause.

1. Irritating angles, or sharpness from malformation of a tooth. In this case the tooth has a found appearance, and the crown is felt to be too pointed or sharp.

2. Irritating angles, or sharpness from an oblique fracture of a tooth; as sometimes happens from biting hard nuts and other substances. The case can be detected on ocular examination.

3. Irritating angles, or sharpness from the tooth being worn obliquely. This is the most common case.

The cure requires that the pointed or sharp part of the tooth be removed either with a file or a pair of cutting forceps; but if this cannot be accomplished, the tooth should be pulled out.

Fractures of the Teeth.—A fracture of a tooth is a solution of it into two or more fragments.

The solution of continuity may be transverse, oblique, or comminuted. The most common kind of fracture is the separation of a particle of the enamel from the rest.

TEETH.

The effects are, considerable pain in the tooth, and sometimes convulsions; an unpleasant sensation in the tongue upon its touching the fracture. An oblique fracture hurts the tongue, lips, or cheek, by its pointed form. The broken surface of a tooth not unfrequently becomes carious.

The species are:

1. Fracture from violence; as occurs in a fall upon the teeth, a blow on them, or in biting the hard stones of fruits, or in an imperfect extraction of a tooth.

2. Fracture from previous caries, or fragility of a tooth. When either of these causes is present, a very inconsiderable force will break the tooth, and split it into several pieces. The surface of the fractured part ought to be kept covered for several days with mastic.

The fracture of a tooth is an incurable accident.

Fissures of the Teeth.—A fissure of a tooth means a solution of continuity, like a mere line, or a crack in the enamel.

For the most part, the cause originates from biting the stones of fruit, or other hard substances.

The effects are pain and tenderness of the tooth, and, in consequence of the entrance of fordes into the fissure, caries is frequently produced.

The treatment consists in filling up the fissure, while recent, with gum mastic.

Luxations of the Teeth.—The luxation of a tooth means the displacement of it from its natural position in the socket, occasioned by violence.

The causes are biting hard or resisting bodies with extreme force; falls or blows upon the teeth; but, most commonly, the accident is brought on by an imperfect and unsuccessful attempt to draw a tooth.

The disfigurement, arising from the wrong posture of the tooth, is the chief effect. The tooth may be put into its right position again with the aid of a pair of forceps.

Stupor of the Teeth.—This is a very singular sensation in the teeth, which cannot be described by words. It was called by the Greeks *hamodia*, from *αἰμαδιῶν*, *obstupesco*: the French term it *l'agacement des dents*.

The proximate cause is a peculiar affection of the nerves of the teeth.

With regard to the effects, this annoying sensation prevents mastication, and excites a preternatural secretion of the saliva; while it is exasperated by the entrance of air into the cavity of the mouth. For the most part, the complaint is only of a transient nature.

The species are:

1. Stupor of the teeth from eating unripe fruit. Hence we find, the affection is often caused by eating sour cherries, currants, gooseberries, &c.

This case may be relieved by chewing sweet almonds, or applying fomentations to the teeth.

2. Stupor of the teeth from vomiting dark bilious matter from the stomach. The secretions thrown up from the stomach are sometimes of an astringent acid kind, and therefore may give rise to this affection of the teeth. Plenck has many times noticed the occurrence in hypochondriacal subjects. *Doctrina de Morb. Dentium*, p. 42.

The cure demands emetics and absorbents, or mild alkaline remedies.

3. Stupor of the teeth in ricketty subjects. The teeth of persons who labour under rachitis, are, on account of their greater sensibility, particularly exposed to the attack of this complaint.

Besides the radical cure of rachitis, which is to be attempted by tonic and absorbent medicines, external palliative means are not to be omitted.

4. Stupor of the teeth from harsh noises. Thus the pain-

ful sensation is brought on by the acute rough sound made by filing various substances, scraping slate, sawing stone, &c. In a fright, the gnawing of the teeth has been observed to have a similar effect.

Odontalgia, or Tooth-ache.—This signifies pain in one or more of the teeth; the etymology being *ὄδους*, *dens*, and *ἀλγία*, *dolere*.

The proximate cause is an irritation of the nerves which are distributed to the teeth and gums.

As for the effects, the pain in the teeth sometimes rises to such a degree, that restlessness, fever, delirium, spasms, convulsions, faintings, &c. are produced, especially in persons of irritable constitutions.

The cheek of the painful side very often swells upon a little abatement of the complaint taking place; the patient drives considerably; and mastication cannot be performed without an increase of suffering.

The different species of the complaint are as follows:

1. *Odontalgia rheumatica*, or the tooth-ache occasioned by the rheumatism affecting the gums and teeth.

The symptoms of this case are, pain in the teeth, without any thing ailing the gums, as far as can be detected by ocular examination.

The cure demands purgative medicines, and afterwards sudorifics.

Externally, wine and water; or vinegar, in which the radix pyrethri has been boiled; the smoking of tobacco; sinapisms to the cheek; or blisters upon the temples, or nape of the neck; are esteemed amongst the most eligible means of relief.

2. *Odontalgia catarrhalis*. This case is mostly brought on by a cold atmosphere and the suppression of perspiration, or from sudden exposure to cold while the body is very much heated.

This species may be known by the presence of the usual symptoms of catarrh, the discharge of mucus from the nostrils, cough, &c.

It admits of relief by the same means which are proper for a catarrh, or the rheumatic species of tooth-ache.

3. *Odontalgia inflammatoria*. The complaint is brought on by inflammation of the gums. Such inflammation oftentimes affects, at the same time, all the neighbouring parts, as the cheeks, ears, eyes, and indeed sometimes the whole head.

Frequently the case brings on, in a slow manner, the formation of abscesses between the gums and cheek, which abscesses, after a great deal of violent pain, burst.

This tooth-ache is exasperated by every kind of warm medicine, whether given inwardly, or used as an external application.

The cure of the complaint in its early stage demands venesection, purgatives, nitre, and other antiphlogistic remedies.

Externally, there is no better application than the aqua plumbi superacetatis.

4. *Odontalgia arthritica*, or *odontagra*, arises on the abatement of a gouty affection of the joints, but subsides again as soon as the latter disease recommences.

5. *Odontalgia venerea*. Both the venereal disease itself, and the mercury which is administered for its cure, not unfrequently give rise to severe tooth-ache. In each of these cases, purgatives are indicated, and afterwards an emulsion of gum arabic, the warm bath, and the compound decoction of sarsaparilla.

Here drawing the teeth is said to be extremely dangerous, as it is apt to bring on inflammation of the throat, and even fatal consequences.

6. *Odontalgia scorbutica*. This case may be known by the

TEETH.

the existence of the usual symptoms of the scurvy. In addition to an intolerable itching in the gums, very acute pain is also often experienced.

With respect to the cure, topical remedies must be employed, together with such external and internal medicines as are generally requisite for the scurvy.

7. *Odontalgia gastrica* is an acute pain in the teeth and gums, arising from a wrong state of the *primæ viæ*.

It may be cured by emetics, purgatives, and other medicines calculated to put the bowels and stomach into order again.

Odontalgia gastrico-verminosa. People who have worms are frequently tormented with the tooth-ache. Authors attempt to explain the fact as follows: they state that worms in the intestines irritate the great intercostal nerve, which has a strong sympathetic connection with the nerves of the teeth.

The cure demands purgatives and anthelmintic remedies.

8. *Odontalgia ventriculi debilitate, seu irritabilitate*. It sometimes happens that men and hysterical women, whose stomachs are weak and irritable, are afflicted with excruciating tooth-aches, which yield to no remedies but antispasmodics, stomachics, and tonics.

9. *Odontalgia gravidarum*. In the tooth-ache originating from pregnancy, the pain often shifts from one tooth to another, and comes on very repeatedly, although the teeth are frequently perfectly sound. Sometimes the pain is merely sympathetic; but, in most instances, it is connected with that plethoric state of the female constitution known to prevail during pregnancy. Venesection is, therefore, the chief means of relief, and then topical applications may be used.

It is a question, whether the operation of drawing a tooth should ever be performed on pregnant women. There are some women who have such a dread of the instruments for this purpose, that the very sight of them brings on the danger of convulsions and a miscarriage. But, on the other hand, the pain may be so violent as to create a chance of the same evils. Here much address is requisite to persuade the patient to undergo the operation, and at the same time great prudence not to advise it, unless rendered absolutely indispensable by the severity and obstinacy of the pain.

10. *Odontalgia nutricum*. Women who suckle are also particularly subject to be afflicted with excruciating tooth-ache, whether the teeth be sound or carious. When the pain resists the usual means, especially opium and venesection, the tooth must be extracted. This case has been supposed to depend upon a certain sympathy between the *mammæ* and the teeth.

11. *Odontalgia from cutting the dens sapientiæ*. Sometimes great and long-continued pain, delirium, and other alarming symptoms take place, until the tooth has made its way out, or the gums have been divided.

12. *Odontalgia hysterica*. This species of tooth-ache often affects hysterical women a long while, notwithstanding the teeth may be perfectly healthy; nor does it always yield to opium, nor even to the operation of extracting several of the painful teeth.

The treatment requires the warm bath, emollient fomentations to the cheeks, and gargles of the same quality to the mouth.

13. *Odontalgia from the teeth being worn away*. The bony substance of the teeth is so sensible, when deprived of the enamel, that on coming into contact with air, or food, at all too warm, or cold, the most intolerable pain is excited.

14. *Odontalgia from tartar on the teeth*. The tartar separates the gums from the neck and fang of the tooth, so as to expose the latter parts to the cold air, and the stimulating quality of the food. Hence, it is obvious, pain must be the consequence.

The radical cure can only be accomplished by removing the tartar. The complaint may be palliated by the common applications for the relief of tooth-ache.

15. *Odontalgia from a fracture of the body of the tooth*. In this case the nerves of the remaining portion of the tooth are exposed to the air, and sometimes become affected with extreme pain.

Writers recommend for the purpose of relieving this complaint, either applying the cautery to the surface of the fractured tooth, or else covering it with wax, or gum mastich.

16. *Odontalgia verminosa*. Whether the tooth-ache can ever really arise from the presence of worms in a carious tooth, is doubtful. Plenck conceives the occurrence possible, and he proposes as a means of cure the employment of a gargle containing the muriates of ammonia and soda.

17. *Odontalgia periodica* signifies that form of the tooth-ache, which comes on every other day, and resembles in its periods of attack an intermittent fever.

In the treatment, authors recommend the use of purgatives, emetics, and the Peruvian bark.

18. *Odontalgia cariosa*. It is not every sort of caries of the teeth which is accompanied with pain; but only the internal or external humid kind of caries. In the dry caries, and also in the humid, when all the nervous filaments of the bone of the tooth have been destroyed by it, the carious tooth remains free from pain.

In the tooth-ache from caries, the following modes of relief are recommended:

1. Pressure upon the nerve which comes out of the infra-orbital canal of the superior maxillary bone.

2. Pressure upon the nerve which passes out of the *canalis mentalis* of the lower jaw-bone.

3. Sulphuric acid applied to the carious part of the tooth by means of a probe. Plenck has sometimes found this plan useful.

4. *Vinum pyrethri*, vel *rutæ*, or strong vinegar.

5. *Sinapisms* to the cheek.

6. Blisters to the nape of the neck, and behind the ears.

7. The application of a magnet to the painful tooth.

8. Oil of cloves introduced into the carious tooth.

9. Camphorated milk retained for a time in the mouth.

10. Burning the nerve with a heated probe.

11. Opium applied to the carious tooth, or administered internally.

12. Luxating the painful tooth is another mode of relief which has been proposed. With the aid of a suitable instrument the tooth is to be turned a little round in its socket, and then turned back again into its natural position. Thus, the small nerve, which enters the hole in the fang, is either broken or rendered paralytic.

Caries of the Teeth.—This signifies an erosion of the substance of the teeth.

The *dentes molares* are more frequently than the rest of the teeth affected with caries, and the *dentes sapientiæ* oftener than any of the other grinders.

Caries of the teeth varies in respect to its situation, figure, nature, and cause.

In regard to situation, the caries may take place in one, in several, or in all the teeth. It may occur upon the external

TEETH.

ternal or internal surface of a tooth; upon the body or the fang of a tooth; or it may affect every part of it.

As to causes, the caries may proceed from such as are properly called external, as a fissure; a wearing away of the enamel; fordes adhering to the teeth; tartar; a detachment of the gums; a violent effort to bite, by which the apex of the fang, or the bottom of the socket, is contused; the use of mercury; cosmetics; the application of acids, especially those which are termed mineral; dentifrice powders containing alum; cold damp air; smoking, or chewing tobacco, &c.

Sugar has been imagined to be hurtful to the teeth; but probably without real foundation. General de Beaufort ate every day for forty years a pound of sugar, and lived to the age of seventy. After death, his viscera were found free from disease, and his teeth sound. (*Anecdotes de Médecine*, tom. ii. p. 35.) Plenck put a healthy tooth into some syrup diluted with water, and kept it there two months, at the end of which time it was taken out, and found to have undergone no change. *Doctrinâ de Morb. Dentium*, p. 52.

The internal causes are scurvy, rachitis, scrofula, &c.

In relation to the particular nature of caries of the teeth, there are two species; one termed humid, which quickly destroys the tooth affected with it; the other is the dry caries, which advances slowly, lasts a long while, is altogether indolent, and cannot be palliated by any known remedy.

The effects of caries are fetor of the breath; repeated attacks of tooth-ache; infection of the neighbouring teeth; and not unfrequently the corresponding tooth on the opposite side of the mouth becomes also affected with caries, as several authors whimsically suppose, from nervous sympathy. In the situation of the diseased tooth, especially, over the carious fang, the gum is most commonly attacked with a parulis, or epulis. Sometimes chronic ophthalmia originates from the irritation of the diseased fang (*Journ. de Méd.* tom. xxxvi.); or else a fistula of the gums or cheek, or an ozæna of the antrum Highmorianum. Even a locked-jaw has been known to arise from carious teeth. *Truka Com. de Tetano*, p. 151.

In respect to figure or form, the following species of caries may be established.

1. Caries foraminosa, or a carious canal, which runs from the external surface of the crown, and penetrates the substance of the tooth.

In the treatment, it is proper to clean out the carious canal with a needle, and by injecting a fluid into it. Then it is to be burnt with a heated needle; and, lastly, closed with wax, mastich, gold, or lead.

2. Caries of the whole crown or body of a tooth. When the middle of the crown of a tooth is eroded in such a manner, that the caries is wider superficially than it is more deeply, then the gold, or lead, or whatever is used for filling it up, cannot be retained in its place.

In this circumstance it becomes necessary to burn the carious surface with a suitable instrument; or to destroy it with caustic applications; or to apply antiseptics.

But when, notwithstanding all these means, the caries yet spreads, the tooth ought to be extracted, in order to remove the pain, prevent the occurrence of other diseases, and not incur the risk of the tooth breaking in pieces in the attempt to take it out at a later period, when it may be excavated and rendered too thin.

3. Caries maculosa. If the superficial spot only appear upon the external surface of the tooth, it may be removed with a file.

4. Caries striata. When the caries occurs in the form

of a longitudinal black streak, it is either in the middle of the crown, or on the lateral margins of the tooth. This case may be occasioned by the teeth being placed too closely together, and also by the use of cosmetics. It admits of being taken off with a file.

5. Caries of the fang of a tooth. The body of such a tooth is sometimes found. The tooth, however, is frequently painful, the cheek of the affected side, and the gum near the painful tooth swell, and an abscess is formed, which is less common in the other species of caries.

The cure requires that the tooth should be drawn out as soon as the inflammation has subsided. It is reckoned dangerous to perform the operation while the parts are much inflamed.

6. Internal caries of a tooth. In this complaint the tooth is painful, and exhibits a leaden colour, and if it be shaken with an instrument the pain is considerably exasperated. Thus the diseased tooth may be detected amongst many which are healthy, even when several of them are thought by the patient to be unsound.

The cure requires the tooth to be extracted.

7. Caries of all the teeth. This affliction is sometimes induced by the scurvy, and rachitis. The radical cure is of course impossible; but the progress of the caries can be checked by the internal use of antiscorbutic medicines, the remedies against rachitis, and by giving assa-fœtida.

Externally, antiseptic washes may be useful.

Plumbatio dentis is the filling of the carious cavity with thin sheet-lead, tin, or gold. Gold is preferable to lead, which is apt to be acted upon and dissolved by acid food, and may therefore produce the saturnine colic; but, on the other hand, lead is more easily introduced into the tooth, and it can be more firmly fixed there. Some dentists give the preference to tin.

The operation is proper, if the carious tooth has a narrow entrance. It can only be performed on the incisors, canine teeth, and first grinders, which are furnished with but one fang.

The operation is contraindicated, when the orifice of the caries is wider than its bottom, as the lead cannot then be retained. Also, when pain and inflammation are present, the introduction of the lead must be deferred until these symptoms have subsided.

The instruments for this operation are,

1. The introducer.
2. The perforator.
3. The planatorium.
4. The file.
5. The plates or leaves of gold, about three or four times as thick as those commonly met with.

As for the operation itself,

1. A thin plate of lead, tin, or gold, is to be put into the hollow of the tooth, by means of the instrument called the introducer.

2. The lead or gold is to be gradually compressed more and more closely, so that it may fill up well the sides of the cavity. This is to be done with the planatorium. Then some holes are to be drilled in the metal with the perforator, and these are to be filled with lead. Lastly, the place is to be rendered even and smooth with the file.

The lead, for some days after the operation, proves rather disagreeable to the tongue; but, in a short time, the patient is habituated to it, and he experiences no longer any such inconvenience.

Sometimes pain and inflammation follow; in which case, the lead must be taken out for a few days with a pointed instrument.

TEETH.

There have been persons who have had lead in their teeth seventy years, and upwards, without any annoyance from it.

Of drawing or extracting a Tooth.—We shall conclude this article with a few observations upon the surgical operation of extracting a tooth from its socket.

The following cases make the performance of it necessary.

1. A carious tooth, producing a severe degree of pain, which can be abated by no remedies.

2. A sharp tooth, which irritates and hurts the tongue, and does not admit of being amended with the file.

3. An ulcer, or abscess of the maxillary sinus.

4. A tooth which renders the socket carious, or causes abscesses, or excrescences of the gums, fistulæ of the jaw, or some other troublesome complaints.

5. A milk-tooth not being shed at the usual period, and its presence forcing one of the permanent set to grow in a wrong direction.

6. A tooth growing out of the palate, or in any other unnatural place.

On the other hand, the operation is contraindicated, when the gums are highly inflamed; or when a tooth-ache, excited by mercury, or the scurvy, is present. Drawing a tooth, in these circumstances, might give rise to extensive inflammation and angina in a dangerous degree.

The common instruments are,

1. The odontagra.

2. The pelicanus.

3. The clavis, or key.

These three instruments are objectionable in one respect: namely, they pull the tooth out of its socket obliquely; and hence they often break the alveolar process, or the tooth itself.

4. But the tooth-instrument which Aitken has described, draws the tooth out of the socket perpendicularly; and, on this account, has an advantage. See *Essays on several important Subjects in Surgery*, London, 1771, p. 196.

5. The tooth forceps.

6. The pes caprinus, or punch.

The molares, when they can be firmly taken hold of, may be extracted with either of the first four instruments.

The incisores, canini, and first molares, may be drawn out with the forceps.

Stumps and fangs cannot be taken hold of with these instruments; they must, therefore, be pushed out of the alveolar process with the pes caprinus, or punch, and then be removed with a pair of forceps.

The patient and surgeon are to place themselves as follows.

1. If the tooth be in the upper jaw, and it is to be taken out with the odontagra, pelicanus, or punch; or if the tooth, which is to be drawn, is in the lower jaw, the patient must be seated in a low chair, or on the ground, the surgeon standing behind him.

2. But if the tooth is to be taken out with the key, or from the upper jaw with the forceps, the patient is to sit in a common chair, and the surgeon is to stand in front of him.

The following are the different methods of performing the operation.

1. Of extracting a tooth with the odontagra.

The inner gum of the tooth about to be drawn, is to be depressed with the claw of the instrument nearly down to the alveolar process. The other part of the instrument is to be applied to the crown of the tooth.

While the thumb is employed in making firm pressure

upon the claw, the handle is to be held with the fingers, and, under the direction of the palm, the tooth is to be raised perpendicularly from its socket.

By means of the screw, which admits of being turned, the instrument may readily be adapted to the larger teeth.

2. Of drawing a tooth with the key.

The key is applied to the tooth nearly in the same way as the odontagra, except that the thumb of the other hand is placed upon the claw. At the commencement, the key is to be turned very gradually; and the tooth, when it yields, is to be cautiously and slowly raised, lest it slip away, and remain adherent to the gum.

3. Of drawing a tooth with the pelicanus.

The claw of this instrument is to be applied to the inside of the neck of the tooth, while the rotula is to be put upon the two neighbouring teeth. The thumb of the hand not holding the instrument is to be applied to the inside of them, so as to counteract the resistance of the rotula.

4. Of the extraction of a tooth with the forceps.

The neck of the tooth being firmly grasped with the forceps, is to be gradually moved, until it is sufficiently loosened to admit of being taken out perpendicularly.

5. Of taking out a tooth with the pes caprinus, or punch.

The two points of the instrument are to be firmly applied, under the gum, to the lower part of the neck of the remaining portion of the tooth. The thumb of the hand not thus employed is to be covered with some linen, and applied internally. The fang is then to be pushed out of the socket, and removed with a pair of forceps.

With regard to the symptoms arising after the operation: a slight hæmorrhage, and a swelling of the gums and cheek, are the usual consequences. These, however, are free from danger, and, when the mouth is washed with a gargle of tepid vinegar, they are soon relieved.

The more serious consequences, which sometimes occur after the extraction of a tooth, are,

1. A violent and dangerous degree of hæmorrhage.

2. Alarming inflammation of the gums and cheek.

3. Abscesses of the gums; very apt to take place, when the gums have been considerably bruised by the instrument, or when splinters of bone are left behind.

4. A fracture of the alveolar process, or of the palate. This accident is most liable to happen, when the fangs of the teeth diverge, or when the fang and socket have grown together by the process of ossification. The existence of the last case may be known by the neck of the tooth being curved. Here the tooth should always be drawn out towards its concave side.

5. Dislocation of the jaw. This may occur, if the mouth be too much open, or the lower jaw be brought too much forward, in the operation. The luxation ought to be immediately reduced. See **LUXATION**.

6. Fracture of the jaw. See **FRACTURE**.

7. Caries of the socket.

8. Lastly, fracture and luxation of the tooth may be the consequences of an unsuccessful attempt to perform the operation.

In the preceding remarks, we have been chiefly assisted by Plenck's excellent compendium, entitled "*Doctrina de Morbis Dentium*," &c. Lovanii, 1796.

Some interesting observations on the diseases of the teeth, particularly with a view to the question whether these parts are vascular, will be found in the article **CRANIUM**.

For a description of the diseases of the gums, we refer to **GUMS**, *Diseases of*.

TEETH.

A Danish physician, named Hagerup, maintains in certain theses that one may hear with the teeth.

As to animals, there are some fishes which have teeth on their tongues, as trouts; others have them at the bottom of the gullet, as the cod-fish; some, as the great sea-dog or shark, called *canis carcharias*, have three, four, or five rows of teeth on the same jaw; the crocodile three, and those all incisors; vipers have two large crooked canine teeth, which are moveable, and ordinarily lie flat, only being raised when they would bite; and the rana piscatrix, sea-frog, or sea-devil, has whole rows of the like moveable teeth. The toad and cuttle-fish have no teeth, and yet they can bite. See *Anatomy of Fish*.

TEETH, Chemical Analysis of. The teeth closely resemble bone in their composition. The bodies consist of a cartilaginous basis, united with phosphate of lime, and small proportions of other earthy salts. The enamel differs so far only from the bodies, that it contains no cartilaginous matter, but consists entirely of earthy substances. The teeth have been often examined, and with various results, according to the state of chemical knowledge at the period of examination. We do not think it necessary to give an account of all that has been said on the subject, but shall confine our attention principally to the latest and most perfect analyses. We shall begin with the analysis of Mr. Pepys: he found the enamel of teeth composed of

Phosphate of lime	-	-	-	78
Carbonate of lime	-	-	-	6
Lofs and water	-	-	-	16
				100

The bodies of the teeth, according to the same chemist, consist of the following proportions.

	Roots of the Teeth.	Teeth of Adults.	First Teeth of Children.
Phosphate of lime	58	64	62
Carbonate of lime	4	6	6
Cartilage	28	20	20
Lofs	10	10	12
100			

A much more complete analysis, however, of the enamel of teeth has lately been made by Berzelius. He gives the following table of his results, compared with the composition of the bones of the same animals.

	Dried Human Bones.	Enamel of Human Teeth.	Bones of Oxen.	Enamel of Ox Teeth.
Cartilage	32.17	—	} 33.30	} 3.56
Blood-vessels	1.13	—		
Fluate of lime	2.00	3.2	2.50	4.00
Phosphate of lime	51.04	85.3	55.85	81.00
Carbonate of lime	11.30	8.0	3.85	7.10
Phosphate of magnesia	} 1.16	} 1.5	} 2.05	} 3.00
Soda, muriate of				
foda, water, &c.	1.20	2.0	2.45	1.34
100				

Thus confirming a discovery made many years before by Morichini, an Italian chemist, namely, that the enamel of teeth contains fluoric acid; a circumstance which had been called in question by later inquirers.

Fossil Ivory and bone have been found by Fourcroy and Vauquelin to retain proportions of animal matter, varying from 45 to 15 per cent.; a curious fact, and highly illustrative of the powers of intimate mixture, or rather perhaps chemical union, in preventing the destruction of organic substances.

TEETH, Artificial, are those set in lieu of natural ones, which are wanting. See **TEETH, Diseases of.**

TEETH, Mark of, in the *Mangee*. See **MARK and EYE of a Bean**. See also **TEETH, infra**.

TEETH of Fish. See *Anatomy of Fish*.

TEETH, in Rural Economy, little bones fixed in the jaws, which serve not only to reduce the food and nourishment, but shew the age in some animals. The horse has forty teeth, including the tushes, which are thus distinguished. Twenty-four are called *grinders*, being placed at the bottom of the mouth, beyond the bars, twelve on each side of the channel, viz. six above, and six on each side. These teeth continue, and do not give place to new teeth in their room, so that they are of no use in distinguishing a horse's age; and they are subject to wolves teeth. In regard to the other sixteen, twelve of them are called in their infancy *milk* or *foal* teeth, and the remaining four go by the name of *tushes*. The twelve foal teeth are short, small, and white, and are seated on the fore-part of the mouth, six above, and six below: and these change and cast, to give place to others; which, in process of time, become long, large, and yellowish.

These new teeth are distinguished by different names given them, according to their putting forth; and it is the manner of their coming forth that gives the knowledge of the first years of a horse's age.

Of these twelve, four are called *nippers*, four *middling* teeth, and four go by the name of *corner* teeth. The four nippers are seated on the fore-part of the mouth, two above, and two below. When a horse has put forth these, he is concluded to be from two and a half to three years old.

The middling teeth are placed near the nippers or gaterers, one above, and one below, on each side of the jaws. They come out and appear between three and a half and four years.

The corner teeth are placed still more forward in the mouth, one above, and one below, on each side of the jaws.

They begin to shoot between the fourth and the fifth year, and are got above the gum at five years; and when surmounting the gum at that age, they become hollow, and mark commonly till seven or eight years. By marking is meant, that in the hollow or cavity of the corner teeth a little black speck is formed, which, from its resemblance, is called the bud or eye of a bean, or the mark. But when the horse passes six, the cavity begins to fill, and the black mark disappears by degrees; yet this diminution of the cavity and the mark continues from six to seven and a half. However, at eight years, the cavity is filled up, and the black mark gone; and the tooth is then full, and even as if it had been shaved. It is then said, that the horse has *raised*, which happens a little before the eighth year; and after that, the horse does not mark; so that the surest knowledge of his age is then formed from his tushes.

The tushes are placed beyond the corner teeth, upon the bars, two on each side below, without being preceded by any foal teeth. The two under tushes cut sometimes at three years, sometimes at three and a half, sometimes at four;

four; but the two upper tushes sometimes at four, sometimes at four and a half; sometimes before and sometimes after the corner teeth, without any certain rule; and till the age of six they are chamfered within. And at about ten years of age the two under tushes appear much worn, which serves for that age. After that they grow out in length, and become bare of flesh, because the gum shrinks and retires; and at last, about the fifteenth or sixteenth year, the horse *shells*.

It is sometimes said, that a horse is not capable of any great fatigue till his tushes have cut the skin. See AGE, in *Horseman's lip*.

The teeth in sheep are divided into two kinds, the *incisores* and the *molares*, or the cutting and dividing, and the rubbing and grinding teeth. Such sheep as are full-mouthed have eight of the first sort of teeth; throwing up two every year, consequently lose their sucking teeth. The *incisores* are found to wear down in proportion to the action which they have; but the *molares*, having more strength, and a different form, do not suffer so much in this way.

It has been suggested by an experienced sheep-farmer, that these sorts of young animals mostly renew their first two teeth at from about fourteen to sixteen months of age; and after that, every year nearly at the same time, until they are turned three years old, or, in the technical language of the sheep-master, three shear, when they become full-mouthed; for although they have eight teeth before in the under jaw, it is commonly believed that they only cast and renew the six inside ones. Shepherds, however, differ much on this point, some contending that they only shed the six fore-teeth, while others maintain that they cast the whole eight fore-teeth. The matter is, therefore, not yet well ascertained. Some properly remark, that sheep are very uncertain in their throwing up their teeth; much depending upon their being early or late lambed, well or ill fed, and other similar circumstances. Tups have been known to have four broad or renewed teeth, when by the age, as shewn in the above manner, they ought to have had only two. Some sheep are remarked to be more backward than others, by several months, in proportion to their strength of constitution, and other matters.

In Romney Marsh the teeth of sheep are found to decay much faster, it is believed, than in any other part of the country. Close feeding wears the teeth exceedingly; of course, the teeth of the sheep of those who stock the hardest commonly decay the soonest. The sheep graziers in this district are very particular in mousing their sheep, which are kept or rejected according as their mouths are found to be good or bad; as, where the latter is the case, they have great difficulty in maintaining themselves during the winter season.

It is noticed that sheep, about the time of renewing their teeth, are very tender in their mouths, and do not thrive so well as they do at other seasons. At one season a teg, it is supposed, may starve any sheep by close feeding; but on the renewal of its broad teeth, any sheep may starve it.

In the above district, the barrens or old breeding ewes are generally cast off when they have had their third lamb; though sometimes, if their mouths be good, and they are often better than those that have had only one lamb, they are kept for the fourth lamb: nor is this supposed a bad practice, since by it some valuable ewes may be reserved.

Sheep are seldom kept here to any great age: some favourites are, however, kept till ten years old, without a tooth in their heads. Some have heard of their living twenty years. In the county of Hereford they are said to live to a great age: they live on long grafs in the summer season, and

pease-straw and other similar matters in the winter, which do not wear their teeth so much as when they labour hard on a close short-set turf. See SHEEP.

The teeth of the various other sorts of domestic animals have hitherto been but little noticed or attended to by store or stock masters, though they are probably, in many cases, as much changed, and serve to mark the ages and growths of the animals as much and as certainly, as in the instances and cases which have been given above.

TEETH, *Mammoth's*. See MAMMOTH'S *Teeth*.

TEETH, *Wolf's*. See WOLVES' *Teeth*.

TEETH of a *Wheel*, in *Mechanics*. See WHEEL.

TEETHING. See DENTITION, and *Diseases of TEETH*, *supra*.

TEETMOW, in *Geography*, a town of Bengal: 40 miles S.S.E. of Curuckpour.

TEFEE, a town of Brasil, in the government of Para, on the river of the Amazons; 220 miles W. of Fort Rio Negro.

TEFELSDORF, a town of Transylvania; 7 miles N. of Schesburg.

TEFEN, a town of Asiatic Turkey, in Natolia; 28 miles S.W. of Amasieh.

TEFESSAD, or TFESSAD, a town of Algiers, whose ruins extend along the coast of the Mediterranean near a league, supposed to have been the ancient Tipasa; 32 miles S.S.W. of Algiers. N. lat. 36° 32'. E. long. 2° 54'.

TEFETHNE, or TEFTANE, a town of Morocco, on the coast; 60 miles W. of Morocco.—Also, a river of Morocco, which runs into the sea near Mogodor.

TEFFEREG, a town of the archbishopric of Salzburg; 1 mile S. of Windisch Matray.

TEFLIS, a town of Asia, capital of the principality of Georgia, and see of a bishop, founded, according to an old inscription in the citadel, by a certain prince Sarang, A.D. 1063, is situated on the N.W. side of the great plain of Karajoes, at the foot of a hill, occupying both banks of the river Kur, over which is a bridge. This city is surrounded with strong walls, except towards the river; and has a large fortress at the declivity of the mountain, which contains a garrison, and is often made use of as a place of refuge for criminals and debtors. All the houses are of stone, with flat roofs, which serve, according to the custom of the East, as walks for the women. The buildings are neat and clean; but the streets are exceedingly dirty and narrow. The town contains one Roman Catholic, thirteen Greek, and seven Armenian churches. Near it are some warm springs, and hence it is called Thelestokar, or Warm town. In the year 1386, this town was taken by Tamerlane, and the king of Georgia made prisoner. In 1723 it was taken by the Turks; and in 1734 retaken by Kouli Khan. Before it was taken by Aga Mahomed Khan, in 1797, it contained 4000 houses, and 22,000 inhabitants. Although most of the houses, which are neatly built, are now standing, the population does not exceed 15,000 souls. It was for many years the residence of prince Heraclius, and is at present that of the Russian governor and commander-in-chief, who has at all times a large force stationed in the city, to the disgust of the inhabitants, who shudder at the thoughts of their wives and daughters being constantly exposed to the view and importunities of strangers. This circumstance tends to render the Russian name detested by the Georgians: 100 miles N.N.E. of Erivan. N. lat. 42° 45'. E. long. 45° 20'.

TEFTERDAR, the name of an officer of dignity in the Eastern nations. In Egypt he is lord high treasurer of the tribute paid out of the lands to the grand signior. He is named
for

for a year by the Porte, but is generally continued in his office many years. This office is sometimes given to one of the poorer beys, to help him to support his dignity; and frequently to a quiet one, who is not likely to enter into intrigues. For one party never cares that a stirring man of the opposite party should be invested with an office of this dignity. See *DEFTARDAR*.

TEFUT, in *Geography*, a town of Africa, in the country of Darah, formerly the capital of the ancient kings of Darah, now gone to decay.

TEFZA, a town of Morocco, built by the Arabians on the side of a mountain: the surrounding walls are composed of blocks of marble; 70 miles N.E. of Morocco. N. lat. $31^{\circ} 40'$.

TEFZRA, a town of Algiers; 15 miles S. of Tremecen.

TEG, a term used in some parts of the kingdom by the farmers, to express a lamb of a year old. Among sportsmen it denotes a roe of two years old. When a flock of ewes and lambs are turned into a turnip-field, the young lambs of three weeks old will immediately fall to eating the turnips, and scoop them very prettily; but these tegs will not touch them for several days. They usually stay till almost starved to death before they begin, but when they have begun, they soon grow fat.

In the Romney Marsh system of management, both the ewe and the wether tegs are kept upon the upland grass farms during the winter season, by which advantages are gained in various ways. They are by this means enabled to keep more ewes and fattening sheep on their marsh-lands, and to have the tegs when the pastures require them. See *SHEEP*.

TEGADOO BAY, in *Geography*, a bay on the east coast of the most northern islands of New Zealand, discovered by captain, then lieutenant Cook, in 1769. S. lat. $38^{\circ} 10'$. W. long. $181^{\circ} 14'$.

TEGÆA, *JIMMEL*, in *Ancient Geography*, a town of Africa, mentioned by Hirtius, situated S.W. of Leptis.

TEGANAN, an island of the Mediterranean, in the vicinity of that of Rhodes.

TEGAPATAM, in *Geography*. See *FORT St. David*.

TEGAREE, a town of Bengal; 11 miles N. of Kishenagur.

TEGAZA, a town of Africa, capital of a district in Zenhaga; near it is a salt-mine, about 300 miles from the Atlantic, and 400 S. of Cape Non. N. lat. $22^{\circ} 20'$.

TEGE, in *Ancient Geography*, a town of Africa Propria, between the two Syrtes. Ptol.

TEGEA, a town in the S.E. part of Arcadia, at a small distance from the Argolide; and placed by M. D'Anville on the site of the modern Moklia. In this place was a famous temple of Minerva Alea, in which was a statue of the goddess, which was removed to Rome by Augustus. This temple contained a number of other curiosities; and the priesthood in it was exercised by a young female under fifteen years of age. Near this temple was a stadium, in which were celebrated games in honour of Minerva, and others in memory of a victory gained over the Lacedæmonians. The public place was ornamented with statues, and particularly one of Mars Gynecotheone, ($\gamma\gamma\eta\kappa\theta\epsilon\omega\tau\eta\varsigma$) sculptured upon a column. The epithet served to maintain the remembrance of a victory obtained by the valour of the females of Tegea. At a small distance from the public place was a magnificent theatre, encompassed with bronze statues. This city suffered much in the wars which raged in Arcadia in the time of the Achæan league. Pausanias says that here was a temple of Venus Urania, near that which was dedicated to Ceres

and Proserpine. The Tegeates were a valiant people. Herodotus (l. i. c. 61.) mentions them with commendation. The Lacedæmonians ravaged the territory of Tegea, and at length obtained a superiority over its inhabitants.

TEGEA, a town of the isle of Crete, said to have been inhabited by Agamemnon.—Also, a town of Macedonia.

TEGEHET, or *TEGEGILT*, in *Geography*, a town of Africa; 120 miles S.S.W. of Fez.

TEGEL, *ERIC*, in *Biography*, a Swedish historian, and principal secretary to Eric XIV. His father, having incurred the just resentment of Eric, as the cause of the misfortunes that occurred during his reign, was apprehended by Charles, duke of Sudermania the brother of Eric, and put to death at Stockholm in 1568. Charles, however, took the son under his protection, and sent him to Germany for improvement; and when he had visited Spain and Poland, appointed him his secretary. In 1614 he was nominated by Gustavus Adolphus historiographer of the kingdom, and in 1617 a privy-counsellor. He died at Stockholm in 1636, and left several works, of which the following were printed in Swedish: *viz.* "The History of Gustavus I. in two Parts." Stockholm, 1622, fol. "The History of Eric XIV. with Stierman's Remarks;" 16-1721, 4to.

TEGENUM, or *TEGIANUM*, in *Ancient Geography*, a town of Lucania.

TEGERHY, or *TEIGAREA*, in *Geography*, a town of Africa, in the country of Fezzan; 80 miles S.W. of Mourzouk. It is a small town, and collects from its lands little produce besides dates and Indian corn. N. lat. $26^{\circ} 17'$. E. long. $15^{\circ} 5'$.

TEGERN, a town of Bavaria, on a lake called the Tegern See, anciently Lacus Tigurinus. Here is a celebrated abbey, founded by Albert and Ockar, two Bavarian princes; 28 miles S.S.E. of Munich.

TEGESSUS, in *Ancient Geography*, a town of the island of Cyprus.

TEGEWSE, in *Geography*, a town of Africa, near the lake of Marks, anciently called Tichafa; 38 miles S.S.W. of Gafsa.

TEGHURI, a large river of Mingrelia, which rises between the Alani and Soanni hills, and disembogues into the Phasis, 10 versts above the Scharistkali.

TEGIANUM, in *Ancient Geography*, a town of Italy, in Campania, according to Clavier; though others assign it to Lucania, and call it Tegenum.

TEGIUM, a town of Asia Minor, in the Troade.

TEGLA, in *Geography*. See *TUGGALA*.

TEGLIO, a town of Italy, in the Valteline, situated upon the top of a mountain, is a long straggling place, containing about 300 houses, about 9 miles from Tirano, and 12 from Sondrio. Close to the town are the ruins of a fortress, standing upon an insulated rock, and formerly esteemed of great strength. This elevated spot commands a rich and extensive prospect from Tirano to the lower part of the valley, beyond Sondrio, as far as Morbegno. The government of Teglio is said to contain the 12th part of the Valteline; it is the most populous district, and contains about 8000 souls. In a good season, it produces much more corn than is sufficient for the consumption of the inhabitants, and rivals Sondrio and Tirano in the goodness of its wine.

TEGNA, in *Ancient Geography*, a town of Gaul, on the banks of the Rhone, not far from Valentia, to the north; the modern Tein.

TEGOMA, in *Geography*, a town of Africa, in the country of Afoudan; 50 miles S. of Agades. N. lat. $19^{\circ} 10'$. E. long. $12^{\circ} 20'$.

TEGO.

TEGORARIN, a town of Africa, in Biledulgerid; 70 miles N.N.W. of Gardeiah.

TEGUCO, a town of New Mexico, in the province of Culiacan; 40 miles N. of Culiacan.

TEGUIXIN, in *Zoology*, a species of lizard; which see.

TEGULA, in *Ancient Geography*, a town of Sardinia, on the route from Sulci to Nora. Anton. Itin.

TEGULET, in *Geography*, a town of Abyssinia; 180 miles S. of Gondar. N. lat. $9^{\circ} 54'$. E. long. $38^{\circ} 35'$.

TEGUMENT. See INTEGUMENT.

TEGYRA, in *Ancient Geography*, a town of Greece, in Bœtica.

TEHAE', in *Geography*, a town of Curdistan; 30 miles E. of Amadiéh.

TEHAMA, a sandy belt which encompasses the peninsula of Arabia, beginning at Suez, and terminating at the mouth of the Euphrates. It is of various breadth; for the most part about two days' journey from the sea-shore to the rise of the hills; or at least this is the breadth of the plain adjacent to the Red sea. It bears every mark of having been anciently a part of the bed of the sea. Its bottom soil is a greyish clay, with a large proportion of sand, and having marine exuviz interspersed to a great distance from the sea-shore. It contains large strata of salt, which in some places rise up to hills. Its regular inclination towards the sea indicates that it has emerged gradually. The small eminences on the confines of this plain are composed of calcareous stones, with a blackish appearance, as if they had been burnt by the sun. The adjoining hills contain schistus and basaltes. The sea, it is thought, still continues to recede, and the Tehama on that side is gradually extending its limits. History confirms these appearances of the gradual recession of the waters; and mentions, as sea-ports, several places which are at present inland, without noticing the present maritime towns, which must have been of later origin than the formation of the land on which they stand. These newly-formed lands, however, are barren and unfruitful.

TEHRAUN, one of the five large districts of the province of Irak, in the Persian empire: the other four being Ispahan, Naen, Mullayer, and Kermanshaw. Tehraun is also the name of the present capital of Persia, which is rendered interesting by the surrounding scenery. To the S. are the extensive ruins of the grand and once proud city of Rae; to the E. the mountains of Elburz (famed in the Persian traditions as the abode of dæmons); to the N. the snow-clad summit of the lofty Dumavend; and to the W. a plain enriched with cultivation and villages, and forming a delightful contrast with the rugged and stupendous rocks which skirt it on the N. and S. Tehraun is about four miles in circumference, surrounded by a strong wall, flanked by innumerable towers, and a noble dry ditch, with a glacis between it and the wall. The only building of consequence within the city is the citadel, which contains the palace of the sovereign and his officers. It was founded by Kurim Khan, enlarged by the late king, and beautified by the present sovereign. The fortifications can be considered as formidable only in a country where the military art is unknown. The population is variable, being in summer about 10,000, and in winter not less than 60,000 people. The environs of Tehraun are not unpleasent; the plain, to the E. and W., being covered with villages, and abounding in grain. On the N. side the king has completed a palace, which, from its situation, and the fine gardens that surround it, is a most delightful residence. There are many reasons which have probably induced the late king to fix upon Tehraun as the capital of his dominions. Its central situation, and the easy defence

which it affords to the Persian empire; the fertility and productiveness of the surrounding country; the number of wandering tribes that have settled round it, and that may be easily and soon assembled; and above all, perhaps, its proximity to Astrabad, the native city of Aga Mahomed Khan, and also to Mazanderan and Dahestan, countries possessed by the Kajer tribe, of which he was the chief, and on whose power and affection to his person his authority was in a great measure founded;—all these considerations might have induced him to make this city the capital of the empire. N. lat. $35^{\circ} 40'$. E. long. $50^{\circ} 52'$.

TEHROOT, or ZEHEROOT, a town of Persia, in the province of Kerman, surrounded by numerous gardens; 8 miles N.W. by W. from Subzistan, and about 52 miles from the ruins of Bumm.

TEHUACAN, or TEGUACAN, a pleasant town of New Spain, between Oaxaca and Orizava. It is situated in a delightful vale, near a river of the same name, called also Rio Grande, of a nitrous quality, and so petrifying a nature, that the shores resemble ruinous walls. It has four churches; and the streets, squares, and houses are neat and modern. The chief market is that of wheat, which is excellent, and the pomegranates are highly esteemed. Besides numerous families of Spaniards and Mulattoes, here are about 2080 Indians. In the vicinity of this town are two wheat-harvests, one in May, the other in September.

TEHUELS, a large lake of South America, towards the S. of Chili.

TEHUKHA, a town of Thibet; 4 miles S. of Jhanfu Jeung.

TEICHOPŒUS, *τειχοποιος*, among the Athenians, an officer who had the care of the city walls; their number was the same with that of the tribes, every tribe having the choice of one.

TEIGN, in *Geography*, a river of England, in the county of Devon, which runs into the English Channel at Teignmouth.

TEIGNMOUTH, a market-town in the hundred of Exminster, and county of Devon, England, is situated, as its name imports, at the mouth of the river Teign, and is sheltered on the east and north-east by a chain of hills, near the foot of which it stands. It is distant from Exeter 12 miles S. by E., and from London 187 W.S.W. A small rivulet divides the town into two parts or parishes, called West and East Teignmouth. The town is recorded to have been burnt in the tenth century by the Danes, who, having landed here, and defeated the king's lieutenant, ravaged the country to a considerable extent. It was also nearly consumed in the reign of queen Anne, when the French landed and set fire to it: one of the new streets, erected with the money procured by a brief for the distressed inhabitants, was named French-street, as a memorial of the calamity. Since that period the town has become of much greater importance, and is now one of the most fashionable watering-places in the western part of England. The principal resort of company is East Teignmouth, where the public rooms and theatre are situated: the former, a neat building, contains tea, coffee, assembly, and billiard-rooms; the theatre has been recently built on a spot of ground given by lord Courtenay, and was first opened in the summer of 1802. A walk or promenade leads from the public rooms towards the south, over an extensive flat called the Dan, on which is a small fort erected for the defence of the town. The view hence, up the river, is extremely beautiful; the ground gradually rising on each side into verdant hills, well cultivated, and adorned with woods. The cliffs overhanging the sea have a singular appearance, being, with the exception of

a few broad patches of verdure, of a deep red colour, and mount in rude irregular shapes to the height of seventy or eighty feet. Near the centre of West Teignmouth is the church, a very ancient stone fabric, built in the form of a cross: the roof is supported in a singular manner by the ramifications of a wooden pillar, that was formed from the trunk of a single tree. East Teignmouth church is a venerable pile near the beach, and, from the appearance of its architecture, was probably one of the earliest structures erected after the coming of the Normans. The trade of Teignmouth consists chiefly of commercial intercourse with Newfoundland; the exportation of clay, and the importation of coal; and is carried on principally in craft built at the place, where are conveniences for launching vessels of a hundred tons. The clay exported is brought from Bovey, for the most part by a canal; and dug on the estate of James Templar, esq., who, with true patriotism, is employed indefatigably in promoting the solid interests of his country, by improving agriculture, and encouraging manufactures. West Teignmouth had anciently a chartered market, held on Sundays; but this was discontinued by order of the sheriff in the reign of Henry III. The market is now held on Saturdays. Salmon, trout, whiting, mackerel, and various other kinds of fish, are taken here; and by some excellent local regulations, the inhabitants have the privilege of supplying themselves before any can be sold to the dealers. The lord of the manor holds a court-baron, or court-leet, in the town once every year: at which court a jury is nominated, two constables deputed and sworn, and a portreeve chosen, who is invested with considerable authority. In the population return of the year 1811, West Teignmouth was stated to contain 441 houses; East Teignmouth, 188; the inhabitants of the former being 2080; of the latter 813: making an aggregate of 2893 persons, occupying 629 houses.

Nearly opposite Teignmouth, and almost under the promontory called the Nefs, is the hamlet of Shaldon, the property of lord Clifford, which has lately become a favourite summer residence for many families who visit the watering places on this coast. The chapel, erected about the year 1670, stands in a beautiful situation, a little above the Teign, about three quarters of a mile from the hamlet, and is approached by a level walk shaded with luxuriant trees.—*Beauties of England and Wales*, vol. iv. Devonshire. By J. Britton and E. W. Brayley, 1807. Warner's Walk through the Western Counties, 1800.

TEIJEUT, a town of Morocco; 15 miles S.E. of Mogador.

TEIL, a river of France, which runs into the Atlantic, N. lat. 47° 39'. W. long. 3° 8'.

TEIL, *Le*, a town of France, in the department of the Ardeche, on the Rhone; 12 miles S. of Privas.—Also, a town of France, in the department of the Ille and Vilaine; 15 miles S.E. of Rennes.

TEILLEUL, *Le*, a town of France, in the department of the Channel; 6 miles S. of Mortain.

TEIN, a town of Bohemia, in the circle of Pilsen; 6 miles N.E. of Tachau.

TEIN, or *Teyn*, a town of Bohemia, in the circle of Bechin; 4 miles S. of Bechin.

TEINITZ, a town of Bohemia, in the circle of Pilsen; 26 miles S.W. of Pilsen. N. lat. 49° 30'. E. long. 12° 57'.—Also, a town of Moravia, in the circle of Brunn; 27 miles S.S.E. of Brunn.

TEINITZ *Jungfern*, a town of Bohemia, in the circle of Schlan; 8 miles W. of Schlan.

TEINTS, and *Semi-Teints*, in *Painting*, denote the se-

veral colours used in a picture, considered as more or less high, or bright, or deep, or thin, or weakened, and diminished, &c. to give the proper relief, or softness, or distance, to the several objects. See COLOURING.

The word is pure French, where it signifies the same.

TEIRCE, or TEIRS. See TIERCE.

TEISBACH, in *Geography*, a town of Bavaria, on the Iser; 1 mile W. of Dingelgingen.

TEISENDORF, a town of the archbishopric of Salzburg; 12 miles W.N.W. of Salzburg.

TEISKO, a town of Sweden, in Tavastland; 45 miles N.N.W. of Tavasthus.

TEISSIER, ANTHONY, in *Biography*, a voluminous French writer, was born at Montpellier in the year 1632. Having studied Greek and philosophy at Orange, and being destined for the ministry among the Calvinists, he applied to Hebrew and theology at Nismes; and after spending some time in the academy at Montauban, he removed to that of Saumur. From thence he went to Paris, where he cultivated an acquaintance with several learned men; but giving up his designs for the ministry, on account of a disorder under which he laboured, he turned his thoughts to jurisprudence, and took the degree of LL.D. at Bruges. In 1683 he married; but upon the revocation of the edict of Nantes, he was obliged to quit France. He then retired with his wife to Switzerland, and was recommended by Turretin and Heidegger to the family of Escher, a burgo-master of Zurich. Declining to accept advantageous offers if he returned to France, he engaged with the senators of Berne for two years in conducting a French gazette in that city. In 1691 he quitted Berne and went to Zurich; and from thence he proceeded to Brandenburg, where refugees enjoyed common privileges with those of the natives of the country. At Berlin, the elector appointed him historiographer, with an annual pension of 300 crowns, which was successively augmented. He was also honoured with the title of counsellor of legation, and ordered by the elector to translate into French the life of his father, Frederic William, written in Latin by Puffendorf. For this service he was liberally rewarded, though his translation was never printed. He was afterwards employed in composing many works for the instruction of the prince royal; and though his constitution was delicate, he enjoyed good health till his death, which happened in 1715, in the eighty-fourth year of his age. It would exceed our limits to enumerate all his works; an ample account of them may be found in the *General Biography*.

TEI-TCHANG, in *Geography*, a town of Corea; 13 miles N.N.E. of Haimen.

TEITEI, in *Ornithology*, the name of a Brazilian bird, a species of tanagra, in the Linnæan system, called also *guiranhemegeta*, and *guraundi*.

It is of the size of our red-breast, and beautifully coloured.

It sings very sweetly, and is kept in cages, five or six together in the same cage. *Marcgrave's Hist. of Brasil*.

TEITH, in *Geography*, a river of Scotland, formed by streams from several lakes, in the county of Perth, which runs into the Forth, two miles above Stirling.

TEJUCO, the capital of the Diamond district in Brasil, situated in a ravine at the foot of a mountain. Tejuco is separated by the small rivulet of St. Francisco from the opposite mountains. The greatest of the diamond works, called Mandanga, is situated on the river Izgitanhanha, and employs about 1000 negroes, sometimes double this number. This rich river, formed by the junction of several streams, is as wide as the Thames at Windsor, and in general from three

to nine feet deep. The part now working is a curve or elbow, from which the current is diverted into a canal cut across the tongue of land round which it winds; the river being stopped below the head of the canal by an embankment formed of several thousand bags of sand. The deeper parts of the channel of the river are laid dry by large caissons, or chain-pumps, worked by a water-wheel. The mud is then carried off, and the *caçalhão* is dug up and removed to a convenient place for washing by machinery adapted to this purpose. The contrivance for obtaining the diamonds from the *caçalhão* is particularly described by Mr. Mawe, *ubi infra*. Tejuco is situated in a sterile district, which produces nothing for the maintenance of its inhabitants, whose number is about 6000; and therefore depends for a supply of provisions, on farms situated at the distance of several leagues. Nevertheless, Tejuco may be called flourishing, on account of the circulation of property created by the diamond-works in its vicinity. The annual sum paid by government for the hire of negroes, salaries of officers, and various necessaries, such as nitre and iron, does not amount to less than 35,000*l.* and this, added to the demands of the inhabitants of the town and its neighbourhood, occasions a considerable trade. The shops are stocked with English cottons, baizes, and cloths, and other manufactured goods; also hams, cheese, butter, porter, and other articles of consumption, which are brought on mules from Bahia and Rio de Janeiro. Tejuco, from its situation on the side of a hill, is very irregularly built; its streets are uneven, but the houses in general are well constructed, and in good condition, compared with those of other towns in the interior. Its name, signifying in the Portuguese language a muddy place, is derived from places of that description near it, which are rendered passable by being covered with large pieces of wood. The diamonds are locked in the treasury under three locks; and those found in the district are deposited every month, as they are received from the works; they are carefully weighed, and some of them selected and kept separate. The average quantity obtained may be estimated at from 20,000 to 25,000 carats annually, which are sent under a military escort to Rio, and there lodged in the treasury. The diamonds are tied up in black silk bags, and deposited in elegant inner cabinets, all which are locked up in strong chests, bound with iron. Tejuco affords some good barley, but grafs for cattle is scarce and dear. Most parts of the country abound in oranges, pines, peaches, guavas, and a great variety of indigenous fruits: ginger and pepper grow spontaneously, and many spices might probably be cultivated with success. Mawe's Travels in the Interior of Brazil, 1812.

TEJUGUACU, in *Zoology*, the name of a species of lizard, common in the Brazils, and called also *temapara*.

It much resembles the iguana in its general figure, but differs from it in that its whole body is black, only variegated with some white spots. It lives principally on the sucking of eggs, but it is capable of bearing hunger a long time; Marcgrave having kept one alive seven months without eating. This species afforded also a certain testimony to that author of the reproduction of the tail when cut off. Ray.

TEIUM, in *Ancient Geography*, a town of Asia Minor, situated on the Euxine sea, on the frontiers of Paphlagonia, near the small river Billis, 370 stadia from the town of Heraclea. It was a Greek Ionian colony, which derived its name and its origin from *Tios*, a Milesian priest, according to Arrian and Mela. The worship of Jupiter named Patarus was practised in this town, according to Demosthenes. On the E. the territory of this town was bounded by the river Parthenius. The town was much augmented when the empire of the Persians was destroyed.

TEIUNHANA, in *Zoology*, the name of a small American lizard. It is about the thickness of one's little finger, and has a sharp nose. Its tail is very slender, six fingers breadth long, and terminates in a point almost as sharp as a needle. Its head is covered with scales; and its back, sides, and legs, with a tender skin, as soft as fat to the touch; and its tail is covered with extremely minute scales, of a square figure. Ray.

TEKAT, in *Geography*, a town of Asiatic Turkey, in Natolia; 10 miles N. of Kiangari.

TEKEBI, a town of Egypt; 22 miles W.S.W. of Damietta,

TEKEH, a town of Turkish Armenia; 40 miles S.E. of Trebisond.

TEKEREE, a town of Hindoostan, in Candeish; 14 miles E. of Barrawnay.

TEKIN, a town of Asiatic Turkey, in Caramania; 100 miles W. of Tocat.

TE-KING, a city of China, of the second rank, in Quang-tong, near the river Si; 1064 miles S.S.W. of Peking. N. lat. 23° 12'. E. long. 111°.—Also, a city of China, of the second rank, in Quang-tong; 1065 miles S. of Peking. N. lat. 23° 12'. E. long. 110° 50'.

TEKKIUR DAG, a mountain of European Turkey, in Romania; 32 miles S.S.E. of Adrianople.

TEKLA, a town of Bohemia, in the circle of Chrudim; 6 miles S.W. of Leutmischl.

TEKMABAD, a town of Persia, in the province of Segestan; 70 miles E.N.E. of Bost.

TEKOA, a village, and anciently a city of Palestine, built by Rehoboam, king of Judah, and considerable ruins appear of its ancient grandeur. It was the native place of the prophet Amos; 9 miles S. of Bethlehem.

TEKOLY, a town of Hindoostan, in Bahar; 53 miles S.S.W. of Patna.

TEKUPHÆ, or *THEKUPHÆ*, in the *Jewish Chronology*, are the times in which the sun proceeds from one cardinal point to the next.

The same term is also applied to the moment in which the sun enters a cardinal point: these four terms, or *tekuphæ*, into which the Jews divided their solar year, are observed among the Jews with a great deal of ceremony; the reason, as we are informed by Munster, is this:

That people have a notion, that in each *tekupha* the sun has a separate angel appointed to guard and direct it; and that in the very point where the sun finishes one *tekupha*, and enters upon another, before the one director has taken place of the other, the devils have a power to exercise all kinds of tyranny in the water.

And hence, they fancy, that if any body drinks the smallest quantity of water at that time, he will infallibly have a dropsy, or some other grievous distemper.

The *tekupha* of Tifri corresponded to the autumnal equinox, that of Tebeth to the winter solstice, that of Nisan to the vernal equinox, and that of Tamuz to the summer solstice.

TEKY SOUND, in *Geography*, a road on the coast of Georgia, south of the Savannah river, where a large fleet may anchor in ten or fourteen fathoms, and have safe entrance over the bar of the river; the flood tide generally seven feet.

TEL ARESIAS, a town of Asiatic Turkey, on the Euphrates; 5 miles W.N.W. of Diarbekir.

TEL Gizir, a town of Asiatic Turkey, in the province of Diarbekir; 16 miles W. of Merdin.

TEL Kiaran, a town of Asiatic Turkey; 30 miles S.S.W. of Diarbekir.

TEL *Musul*, a town of Asiatic Turkey, in the government of Diarbekir; 33 miles N.W. of Mosul.

TEL *el Judieh*, a town of Egypt, where the Jews had formerly a temple, destroyed by Vespasian; 17 miles N.E. of Cairo.

TELA, in *Ancient Geography*, a town of Spain, on the route from Asturica to Saragossa, between Intercatia and Pintia. Anton. Itin.

TELA, or *Constantia*, a place of Asia, in Mesopotamia, near the mountains, about N. lat. $37^{\circ} 25'$.

TELA *Cellulosa*, in *Anatomy*, the CELLULAR Substance; which see. It is sometimes also called tela mucosa.

TELACH, in *Geography*, an island of Russia, in the Penzinskoi sea. N. lat. $61^{\circ} 35'$. E. long. $159^{\circ} 14'$.

TELAMON, in *Ancient Geography*, a promontory of Italy, in Etruria, at the foot of which was a port, between the rivers Almina and Alma. (Anton. Itin.) Pliny calls this port Telamon.

TELAMONE, in *Geography*, a town of the Stato del Presidii, on the coast; 10 miles N. of Orbitello. N. lat. $42^{\circ} 38'$. E. long. $11^{\circ} 6'$.

TELAMONES, a name given by the Romans to what the Greeks called *Atlantes*; viz. the figures of men supporting entablatures, and other projectures. See ATLAS.

The word, according to some, is derived from the Greek *τέλαμον*, from *τέλω*, or *τλαω*, I bear.

Among the Greeks they were called *atlantes*, *ατλαντες*, which comes from the same word, *ταλω*, or *τλαω*, by the figure metathesis.

TELAMONES is also used by surgical writers sometimes for lint, and sometimes for the fillets or bandages which they apply over their dressings.

TELANA, in *Ancient Geography*, a very ancient town of Asia, in Assyria. Steph. Byz. says that the king made it the place of his residence before Nineveh was built.

TELANADING ISLANDS, in *Geography*, three small islands lying east and west, near the N.W. coast of the island of Gilolo. N. lat. $2^{\circ} 18'$. E. long. $127^{\circ} 30'$.

TELANDRIA, in *Ancient Geography*, an island on the coast of Lycia, in Asia Minor. Pliny.

TELANDRUS, a town of Asia Minor, in Lycia. Pliny.

TELAPSAR, in *Geography*, a town of Asiatic Turkey, in the province of Diarbekir; 20 miles W. of Mosul.

TELARUSE, a river of Asia, which forms the north boundary of the kingdom of Queda, separating it from Lower Siam, and runs into the East Indian sea, N. lat. $6^{\circ} 55'$. E. long. $99^{\circ} 42'$.

TELAUGIA, in *Natural History*, the name of a genus of serupi, of a glittering appearance, usually containing flakes of talc, and emulating the structure of the granites. Hill.

Of this genus we have twelve species.

TELCHINES, in *Ancient Geography*, a people who derived their origin from the isle of Crete. They established themselves in Cyprus, and in Rhodes, where it is said they invented the use of iron and brass.

TELCOOTE, in *Geography*, a town of Hindoostan, in Orissa; 20 miles S.E. of Jaypour.

TELDOM HOTUN, a town of Chinese Tartary, on the west side of the river Saghalian; 745 miles N.E. of Peking. N. lat. $49^{\circ} 56'$. E. long. $127^{\circ} 33'$.

TELE, *τελε*, among the Athenians, those revenues that were brought in by lands, mines, woods, and other public possessions, set apart for the use of the commonwealth; as

also tributes paid by sojourners and freed-servants, and the customs laid upon certain trades and goods.

TELEBA, in *Ancient Geography*, a town of Albania, between the mouth of Soana and that of Garrus. Ptol.

TELEBOAS, a river of Asia, in the environs of the sources of the Tigris; furrounded, as Xenophon says, by a great number of villages.

TELEGRAPH, a machine adapted for communicating intelligence at a considerable distance, by making various signals, which have been previously agreed upon between two parties, to represent letters, words, or ideas. The means of making signals that are used in naval and military operations, are not called telegraphs, although they effect in a great degree the same object. See SIGNAL.

The word telegraph, which is derived from two Greek words, *τελε*, at a distance, and *γραφεω*, to write, was brought into use about 1793 or 1794, when the French directory established machines of this kind for communicating intelligence between Paris and all the principal towns in France. The British government soon after adopted the same measure, and it has since become very general.

No machine for making signals can with propriety be called a telegraph, unless it is adapted to express a sufficient number of letters or words to form a complete language, and which can therefore be made to communicate any information which can be expressed by oral or written language. Less perfect systems of signals, which extend only so far as to communicate intelligence of events which have been foreseen, and the appropriate signals previously arranged, are still called signal flags, signal lanthorns, signal guns, or fires, &c.

When people wish to transmit intelligence to others at a distance, in a quicker manner than by letters sent by messengers or carrier-pigeons, it can be done only by signals. These may be employed in three different ways: either by single signals, which, according to previous agreement, convey whole ideas; or by several successive signals, which, by representing letters and words, answer the same purpose; or otherwise, by employing signals which express numbers, each person being provided with a dictionary in which every word has a number affixed to it.

The first kind of signals were employed in the earliest periods, and some of them were suited to the ear as well as to the eye. For the making of visible signals, the ancients employed fire and smoke, torches, flags, &c.; and in modern times, sky-rockets have been used. For the audible signals, they employed drums and trumpets; and since the invention of gunpowder, the firing of cannon has been applied to the like use. But all these methods are incapable of expressing what could be communicated by speech and writing; and the means of expressing all the possible variations and combinations of the letters of the alphabet, form, in a proper sense, the true telegraphic art. Even the signals commonly used at sea, as they extend only to particular circumstances, are, when compared to signals by letters, only a kind of hieroglyphics.

The proposed object of the telegraphic art is, therefore, to obtain a figurative language, the characters of which may be distinguished at a distance. On the first reflection, we find that the practicable modes of such distant communications must be confined to sound and vision; each of which is in a great degree subject to the state of the atmosphere: for independent of the wind's direction, it is known that the air is sometimes so far deprived of its elasticity, or some other quality that influences the conveyance of sounds, that the heaviest ordnance can scarcely be heard farther than the shot flies. It is also well known, that in thick hazy weather, the largest and

most

most defined objects become totally obscured at a short distance. No instrument, therefore, designed for the purpose can be perfect. We can only endeavour to diminish these irremediable defects as much as may be.

The most barbarous nations employed signals, which could quickly inform them of the approach of enemies, as appears by the testimony of several ancient authors; and there is reason to believe that some sort of telegraphic communication was in use among the Greeks. The destruction of Troy was certainly known in Greece very soon after it took place, and before any person could have returned from it. A Greek play begins with a scene, in which a watchman descends from the top of a tower in Greece, and gives information that Troy is taken. "I have been looking out these ten years (says he) to see when that would happen, and this night it has been done."

In addition to the Stenterophonic tube which was known and used by Alexander the Great, the Romans had a method, in their walled cities, either of forming a hollow in the masonry, or of applying tubes to the walls, so as to confine or augment sound, and convey information to any part of their works. In lofty houses and warehouses, it is now a common custom to have a pipe, by way of speaking trumpet, to give orders from the upper apartments to the lower. By this mode of confining its volume, sound may be carried to a very considerable distance; but beyond a certain extent the sound will lose all articulation, and only convey alarm, without giving directions.

Every city of the ancients had its watch-towers; and the castra stativa of the Romans had always some spot, elevated either by nature or art, from whence signals were given to the troops cantoned or foraging in the neighbourhood; but it appears that they had not arrived to any greater refinements in the telegraphic art, than that on seeing a certain signal they were immediately to repair to their appointed stations. Flags or ensigns, with their various devices, are of the earliest invention, especially at sea, where, from the first idea, which was most probably that of a vane, to shew the direction of the wind, they have been long adopted as the distinguishing marks of nations, and are now so perfected into a system of signals, that every requisite order and question is received and answered by the most distant ships of a fleet.

The mode of signalling in use about half a century ago was very imperfect. It was a good deal amended and simplified by that lamented officer admiral Kempenfelt; and his system, as it was called, continued in use till within these twenty-five years. It was superseded in the navy by sir Home Popham's, who first brought into practical utility a plan originally, it is believed, suggested by Mr. Richard Gower, of the East India Company's service, in his "Practical Seamanship," published in 1794. This was the substitution of ten or twelve numbered flags, for a great number of flags. It is surprising that this easy scheme should not sooner have been discovered and adopted. Instead of the immense "colour chest" that we and our naval cotemporaries can recollect, and the difficulty of finding and hoisting the variety of flags required, it is pleasing to witness the facility with which communications can be now made, by means almost as easy of application as the pen.

The system now in use, originating, as we have stated, with an officer of the East India Company's service, has recently been greatly improved by another of these officers. It is not easy to describe the nature of those improvements; nor proper, perhaps, were it otherwise; for the directors of the East India Company have deemed it expedient to keep them secret. The author of them is captain Thomas Lynn. His work was printed in 1814, at the Company's expence, in a

considerable quarto volume, under the title of "Lynn's Improved System of Telegraphic Communication." It is adopted throughout the extensive service of the East India Company; and we are glad to see it noticed in the preface to the volume, that the highly respectable court of directors most liberally patronized the work and its author. We do not find, notwithstanding the manifest advantage of the "Improved System," that it has yet been introduced into the royal navy; although every officer in that as well as the East India Company's service, who have had opportunities of trying it, are loud in its praise. It adapts itself to every description of telegraphic machinery now in use; or, as far as we can see, that can be used: it requires fewer flags than were heretofore necessary; and its powers are vastly greater than the other codes or systems. This paragraph, and perhaps this whole page of our dictionary, can be thus communicated, word for word, or phrase by phrase, without difficulty, and with a rapidity unattainable by any scheme hitherto published. The numbers, and powers, and meaning of the signals, may be changed at pleasure: so that if the work fall into improper hands, it merely communicates the principle on which the system is founded.

In applying this or a similar mode of communicating intelligence in land service, several objections present themselves: the variety of communications necessary to be made is so much greater, that the combination would become too complicated; and if the person for whom the information is intended, should be in the direction of the wind, the flag would then present a straight line only, and at a little distance would be scarcely visible. The Romans were so well aware of this inconvenience of flags, that many of their standards were solid, and the name manipulus denotes the rudest of their ensigns, which was a truss of hay fixed on a pole.

A beacon or bonfire, made of the first inflammable materials that offered, being the most obvious, is perhaps the most ancient mode of general alarm. By being previously concerted, the number of points where the fires appeared may have particular intelligence affixed. The same observations may be referred to the more modern plan of throwing up rockets, whose number, or the places from whence they are thrown, may have affixed significations. Many of our hills still retain the name of beacon hills, from the signals which used to be made upon them, by means of fire and smoke, which were the chief things employed during the dark ages, and in the times of the feudal system. The fire was used by night, and the smoke by day. Within a few years, signals made by these means were very common amongst the smugglers on our coast.

The machine of ~~Aeneas~~ Aeneas, who wrote a treatise on the duties of a general in the time of Aristotle, is described by Polybius to have consisted of two earthen vessels, made exactly similar in all their dimensions: they were to be filled with water, and each was to have a cock or spout, which could be opened or shut at pleasure, and would, when open, discharge an equal quantity of water from both vessels, so that each of the vessels would take precisely the same period of time to discharge the whole, or any given proportion, of its contents. A float of cork was to be provided for each vessel to rest upon the surface of the water, and support a perpendicular stem or index, which could be divided, and have certain sentences written to correspond with each division. The apertures of the spouts of the two vessels were to be previously adjusted, and the vessels filled with water to the same height, so that their floats and indices would correspond in pointing out the same sentences; then, if both cocks were opened at the same instant, the water would run out from each vessel, and the floats of both would subside together, so that when either index
flood

flood at a particular sentence, the other index would, at the same time, point out the same sentence. Now this operation could be equally well performed when the two vessels were moved to any distance asunder, provided the observers were within sight of each other, to be able to make the requisite signals for opening and shutting the cocks of both vessels at the same moment. The author thus describes the use of this instrument: The two vessels being prepared and adjusted, they must be carried to the two places where the signals are to be made and observed; water is poured into each, and the floats and indices are put into the vessels. When any of the events which are written upon the indices shall happen, a torch or light is raised, which must be held aloft till such time as another is raised by the party to whom it is directed. (This first signal is only to give notice that both parties are ready and attentive.) Then the torch or other light must be taken away, and the cocks set open instantly by both parties. When the interval or division on that part of the index where the event, of which notice is to be given or written, shall be fallen to a level with the vessels, then the man who gives the signals lifts up his torch, and on the other side, the correspondent signal maker immediately shuts the cock of his vessel, and looks at what is written on that part of the stick which touches the mouth of the vessel; on which occasion, if every thing has been executed exactly and equally on both sides, both parties will read the same thing.

The proper telegraphic art was not wholly unknown to the ancients. The Greeks and the Romans made use of pots filled with lighted twigs and straw for signals, over which they poured oil; and these being placed in certain rows, expressed certain letters, according to the order in which each row was lighted.

Polybius describes a new method of communication, which was invented by Cleoxenus, or by Democlitus, and which Polybius himself very much improved. It possesses the principal advantage of the modern telegraph, *viz.* that, by means of signals, it communicates the letters of the alphabet, and can therefore be used to express any thing which can be required. It is only inferior to the telegraph in the means of making the signals, which is by the light of torches, and rather complicated, so that it would be tedious to transmit any thing more than short sentences. Polybius describes this method, which he calls *Pyrria*, in the following manner: Take the letters of the Greek alphabet, and divide them into five parts, each of which will consist of five letters, except the last division, in which there will be only four. Let these be fixed on a board, in five columns. The man who is to give the signals is then to begin by holding up two torches, which he is to keep aloft till the other party has also shewn two: this is only to denote that both sides are ready: these torches are then withdrawn. Both parties are provided with boards, on which the letters are disposed as formerly described. Then the person who gives the signal is to hold up torches on the left hand, to point out to the other party, from what column he shall take the letters as they are pointed out to him: thus, if the letter is to be from the first column, he holds up one torch; if from the second, two; and so on for the others. He is then to hold torches on the right hand, to denote the particular letter of the column that is to be taken. All this must have been agreed on beforehand. The man who gives the signals must have an instrument (*δοκτριον, perspective*), consisting of two tubes, and so placed, that by looking through one of them he can see only the right side, and looking through the other, he can only see the left-hand side of him who is to answer. The board must be set up near this instrument; and the stations on the right and left must each be surrounded with a wall ten feet broad,

and about the height of a man, that the torches raised above it may give a clear and strong light, and that when taken down they may be completely concealed.

The *Iteganographia trithemiana* of a Benedictine monk, in the fifteenth century, seems to have been something of the same kind; but the first recorded experiment, after the manner of the Greeks, is described by Kircher, in his "*Arts magna Lucis et Umbræ*," under the title of *Cryptogamia catoptrica*; it was however imperfect, and could be employed only at a certain distance. Schott, in his "*Technica curiosa*," proposes, after an anonymous author, to erect posts upon an eminence, so as to be distinguished through a telescope, and on which proper signals could be elevated, as might be necessary.

The marquis of Worcester, who is so justly celebrated for having first discovered that the force of steam could be applied to mechanical purposes, brought telegraphic communication to a considerable degree of perfection, if at least we give him credit for having really effected every thing which he mentions in his *Century of Inventions*. This little tract was published in 1663, and contains the following articles.

"No. 6. How at a window, as far as eye can discover black from white, a man may hold discourse with his correspondent, without noise made, or notice taken, being according to occasion given and means afforded, *ex re natâ*, and no need of provision before-hand, though much better if foreseen, and means prepared for it, and a premeditated course taken by mutual consent of parties.

"No. 7. A way to do it by night, as well as by day, though as dark as pitch is black."

The marquis gives us no idea of the means which he used for exhibiting his signals, by which we can judge of the practicability of his plan for communicating any detailed intelligence.

Kefslor, in his *Concealed Arts*, advises characters to be cut out in the bottom of a cask, so as to appear luminous when a light is placed within, and the characters must be changed successively to express words and sentences.

Dr. Hooke's Telegraph.—The first idea of a telegraph upon a similar construction to those used at present, was suggested by Dr. Hooke towards the end of the last century, the siege of Vienna by the Turks having turned his attention to the business. He gave the first complete description of such a machine, as appears by the following extract, from a paper of his, read before the Royal Society on the 21st of May, 1684. "I proposed (says he) some years since, a method of discoursing at a distance, not by sound but by sight: I say that it is possible to convey intelligence from any one high and eminent place, to any other that is in sight of it, though thirty or forty miles distant, in as short a time almost as a man can write what he would have sent; and as suddenly to receive an answer, as he that receives it has a mind to return it, or can write it down on paper. Nay, by the help of three, four, or more eminent places visible to each other, lying in a straight line, 'tis possible to convey intelligence almost in a moment, to twice, or thrice, or more times that distance, with as great a certainty as by writing.

"For the performance of this, we must be beholden to a late invention, which we do not find any of the ancients knew; that is, the eye must be assisted with telescopes, that whatever characters are exposed at one station, may be made plain and distinguishable at the other.

"First: For the stations, if they be far distant, it will be necessary that they should be high, and lie exposed to the sky; that there be no higher hill or part of the earth beyond them, that may hinder the distinctness of the characters,

TELEGRAPH.

ters, which are to appear dark against the sky, beyond them appearing white, by which means also the vapours near the ground will be passed over and avoided. Next, in choosing these stations, care must be taken, as near as may be, that there be no hill that interposes between them, that is almost high enough to touch the visible ray, because in such cases the refraction of the air of that hill will be very apt to disturb the clear appearance of the object. The stations being found convenient, the next thing to be considered is, what telescopes will be necessary for each station. One of these telescopes must be fixed at each extreme station, and two of them in each intermediate station; so that a man for each glass, sitting and looking through them, may plainly discover what is done in the next adjoining station, and with his pen write down on a paper the characters there exposed, in their due order; so that there ought to be two persons at each extreme station, and three at each intermediate one, that intelligence may be conveyed backwards and forwards at the same time. Next there must be certain times agreed on, when the correspondents are to expect it; or else there must be set at the top of a pole, in the morning, the hour appointed by either of the correspondents for acting that day.

“Next there must be convenient apparatus of characters, consisting of at least as many distinct characters as there are necessary letters in the alphabet, (to be made use of as is expressed in *Plate Telegraph, fig. 1.*) And these must be either day characters or night characters. If they are to be made use of in the day-time, they may all be made of deals, and of a size convenient for the several distances, any one of which characters may signify any one letter of the alphabet, and the whole alphabet may be varied 10,000 ways, so that none but the two extreme correspondents shall be able to discover the information conveyed. If the characters are for the night, then they may be made with links, or lights disposed in a certain order, which may be covered or uncovered, according to the method agreed on. There will be also requisite several other characters, which may for expedition express a whole sentence, such as ‘I am ready to communicate;’ ‘I am ready to observe.’ I could instance a hundred ways of facilitating the method of performing the design with the more dexterity and quickness, and with little change, but that I think will be needless at present, since, whensoever such a way of correspondence shall be put in practice, those and many more than I can think of at present will of themselves occur, so that I do not in the least doubt but that with a little practice all things may be made so convenient, that the same character may be seen at Paris, within a minute after it hath been exposed in London; and that the characters may be exposed so quick after one another, that a composer shall not much exceed the exposer in swiftness, and this not only at the distance of one station, but of an hundred; for supposing all things ready at all of those several stations for observing and exposing as fast as the second observer doth read the characters of the first exposer, the second exposer will display them to the observer of the third station, whose exposer will likewise display them for the fourth observer, as fast as his observer doth name them to him or write them down. There may be many objections brought against this way of communication, because it has not yet been put in practice, but hardly any that may not be easily answered and obviated.”

Dr. Hooke illustrates his invention thus: Let A B C (*fig. 2.*) represent three very long masts or poles erected, E the top piece that joins them together, D a screen, behind which all the deal-board characters hang upon certain rods or lines, and may, by the help of small lines connected with

each of them, be exposed at F, or drawn back at D, as occasion may require.

This proposal of our ingenious countryman is very complete and well studied; it would be less convenient and expeditious than the modern telegraphs, but would certainly have answered very useful purposes, with the advantage of being very free from the uncertainties and errors of more complete machines, which, at the same time that they admit of making a greater variety of signs than the letters of the alphabet, are for the same reason more liable to mistakes in exhibiting as well as in reading or translating them. The only obvious improvement on Dr. Hooke's telegraph is, that, instead of concealing the characters behind the screen D, they should be kept down below in the house on which the machine is to be erected, and be hoisted up into the frame when they are to be exhibited.

M. Amontons, an ingenious French academician who studied mechanics, was born at Paris in 1663, and died in 1705, at the age of forty-two. He proposed the following method: Let there be people placed in several stations, and at such a distance from each other, that by the help of a telescope, a man at one station may see a signal made in the next before him: he must immediately repeat the same signal, that it may be seen by persons in the station next after him, who are to communicate it to those in the following station, and so on. These signals may be as letters of the alphabet, or as a cipher, understood only by the two persons who are in the distant places, and not by those who make the signals. The person in the second station making the signal to the person in the third the very moment he sees it in the first, the news may be carried to the greatest distance in as little time as is necessary to make the signals in the first station. The distance of the several stations, which must be as few as possible, is measured by the reach of a telescope. M. Amontons is said to have tried this method on a small tract of land, before several persons of the highest rank at the court of France; but we are not acquainted with the kind of apparatus he employed; all that we know of his method is precisely the same as Dr. Hooke's.

Guyot, a long time after Dr. Hooke, proposed tables, with letters cut out in them: and Paulian, in his *Dictionnaire de Physique*, describes a transparent figure, consisting of one perpendicular and three horizontal stripes, forming ten compartments, each of which can be rendered visible or invisible at pleasure, by blinds or shutters moveable from behind.

Mr. Richard Lovell Edgeworth, in a memoir which he presented to the Royal Society of Ireland (see their *Transactions*, vol. vi. p. 125.), adduces proof, that in 1767 he tried an experiment of the practicability of communicating intelligence by a swift and unsuspected mode; and for this purpose he employed a common windmill, and arranged a system of signals, which could be made by the different positions of the arms of its sails, the canvas being removed from one or more arms, as was required. These signals were made to denote numbers, and both parties were provided with vocabularies, in which all the words were numbered.

French Telegraph.—Although the telegraph was thus fully explained in 1684, it does not appear that this valuable invention was at all practised or applied to any useful purpose until 1793 or 1794, when the events of the French revolution had directed all the energies of that ingenious people to the improvement of the art of war. A report made by Barrere to the sitting of the French Convention in August 1794, attributes the invention of the telegraph which they used to citizen Chappe.

“The new invented telegraphic language of signals is an artful

artful contrivance, to transmit thoughts in a peculiar language from one distance to another, by means of machines, which are placed at different distances of from twelve to fifteen miles asunder, so that the expression reaches a very distant place in the space of a few minutes. This is now brought to such a state of perfection, that a correspondence may be conducted with Lisle, upon every subject and every thing: even proper names can be expressed; an answer may be received; and the correspondence thus be renewed several times a day. The only thing which can interrupt their effect is the weather, when the air is so very bad and turbid that the objects and signals cannot be distinguished. By this invention, remoteness and distance almost disappear, and all the communications of correspondence are effected with the rapidity of the twinkling of an eye. By its aid the operations of government can be very much facilitated, and the unity of the republic consolidated much more by the speedy communications with all its parts.

"The greatest advantage can be derived from this mode of correspondence, because, if thought proper, its objects need only be made known to certain individuals, or to one individual alone, or to the extremities of any distance; so that the Committee of Public Welfare may at present carry on a correspondence with the representative of the people at Lisle, without any other persons being acquainted with their objects. If Lisle was even besieged, we should know every thing at Paris that might happen in that place, and could send thither the decrees of the Convention without the enemy being apprised of it, or able to prevent it."

M. Chappe's or the French telegraph is represented in *fig. 4*, which is made from some sketches taken from the telegraph on the palace of the Louvre, at the time of its first establishment, and published in the Monthly Magazine, and other publications.

A B is a beam or strong mast of wood, erected perpendicularly from the centre of a cabin or small house situated on a rising ground: it must be about 15 or 16 feet high above the top of the house. C D is a balance-beam, jointed to the top of the mast, so as to be moveable on its centre, like a scale-beam. This balance-beam, which is called the long indicator, may be placed vertically or horizontally, or any how inclined, by means of strong cords, which are attached to the central wheel or pulley D, which has two grooves in the edge to receive the cords. The long indicator is about 11 or 12 feet long, and 9 inches in breadth; and at each extremity it carries secondary indicators F, G, which likewise turn upon centres or joints, by means of four cords, which are conducted through a hollow in the centre pin or axis of motion of the long indicator, otherwise the motion of the long indicator to put it into different positions, would derange the cords, and alter the direction of the secondary indicators, which are capable of being placed in any position with respect to the long indicator, by those cords being conducted by pulleys down into the cabin, and there attached to other mechanism, by means of which the whole machine is moved, and can be made to assume any of the positions represented by the small figures in the plate, in which positions it forms a variety of different characters, to denote the letters of the alphabet or numerals.

That the indicators may be very light, and at the same time oppose the least resistance to the wind, they are formed by frames, the interior parts of which are filled up by small oblique and separate boards, which however, being seen in front, appear contiguous. The ends of the small indicators are carried beyond the centres, and carry counter-weights to balance the weight of the indicators; but these ends and balances are made so as to be invisible at a distance.

It is easy to find the number of signals possible to be made with this telegraph: for if we consider the great indicator as being fixed, we shall find that each of the smaller ones may distinctly take five different positions: two where it makes a right angle with the great indicator; two where it makes an angle of 45° ; and one where it falls back upon the great one, in which case it will disappear. Three other distinct positions might also be created; one where the small indicator would be horizontal with the great one, and two where it would make an angle of 135° with it.

The lesser indicators then, considered as single movers, will furnish five times five, or twenty-five signals. As the great indicator is also a mover, there are twenty-five times as many signals as this indicator has distinct positions; and as it has but four distinct positions, one horizontal, one vertical, and two inclined, there are in all four times twenty-five, or one hundred signals.

The manner of using the telegraph was as follows: At the first station, which was on the roof of the principal pavilion of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the Committee of Public Welfare, the words to be sent to Lisle, near which the French army was at that time stationed. Each of the telegraphs in the line employed three persons to work it: one to move the machine, which was done by a single motion of a winch, and could therefore be effected in a moment. A second person was employed with a telescope to observe the telegraphs of the two adjacent stations, to receive the communications, and to know by their signals, if they had understood the communication made to them, and also to receive the answers. The third person was employed to write down the observations made by the second person, and to give orders to the first. The stations were about three or four leagues distant, and an observatory was situated near the Committee of Public Safety at Belleville, to observe the last telegraph.

The grammarian will easily conceive that sixteen signs may amply supply all the letters of the alphabet; since some letters may be omitted, not only without detriment, but with advantage. These signs, as they were arbitrary, could be changed every week: so that the sign for B one day, might be the sign for M the next; and it was only necessary that the persons at the extremities should know the key. The intermediate operators were only instructed generally in imitating and repeating these sixteen signals, which were so distinct, and so marked, as different the one from the other, that they were easily remembered. The construction of the machinery within the house was such, that each signal was uniformly given in precisely the same manner at all times. It did not depend on the operators' manual skill, because the position of the arms could never for any one signal be a degree higher or a degree lower than was intended, their movements being regulated mechanically. M. Chappe, having received at the Louvre the sentence to be conveyed, gave a known signal to the second station, which was Montmartre, to prepare: at each station the observers with telescopes were on watch, and each telegraph immediately gave the signal of preparation which he had received; and this being communicated successively through all the line, all the machines were brought into a state of readiness. The persons at Montmartre then received, letter by letter, the sentence from the Louvre, which they repeated with their own machine, and this was again repeated from the next height, with inconceivable rapidity, to the final station at Lisle, where the observations were written down, and translated according to the key which had been before arranged to be used, either by previous concert, or by some particular signal made with the telegraph, to denote that key which was used. The time taken

TELEGRAPH.

taken up for each movement was about twenty seconds; of which the motion alone took up four seconds; and during the other sixteen, the telegraph was kept stationary, that it might be distinctly observed and written down by the people at the next station. The signs were sometimes made for words, and sometimes for letters: when in words, a small flag was hoisted; and as the alphabet could be changed at pleasure, it was only the corresponding persons at each end of the line who knew the meaning of the signs. In general, news was given every day about eleven or twelve o'clock; but the observers were constantly on the watch, and as soon as a certain signal was given and answered, they begun from one end to the other to move their machines. All the moveable parts were painted of a dark-brown colour, to be more distinctly visible when viewed against the bright sky.

Another line of telegraphs, from Paris to Landau, was completed in 1796: the first of them was erected on a pavilion of the palace of the Tuilleries. The construction was more complicated than the first. A fixed black bar, fifty feet long, was supported horizontally by four uprights. This bar carried five indicators, similar to the smaller indicators of the machines before described. Two of the upright posts which supported the horizontal bar, carried each a similar indicator: in this way the centres of the indicators were all stationary, instead of having the long indicator with smaller ones at the extremities. These seven indicators were moved by pulleys, in the usual way; and there was none of the difficulty of conveying the communicating cords through the hollow axis of the central pulley. Each of the indicators could take seven distinct positions; *viz.* for those which were supported by the horizontal bar, two vertical, four inclined, and one horizontal; and for those indicators which were supported by the upright posts, one vertical position, four inclined, and two horizontal ones. The number of combinations which such a construction can make, is $7 \times 7 \times 7 \times 7 \times 7 \times 7 \times 7$, which gives the astonishing number of 823,543 signals. This number, which is eight thousand times larger than that of the signals of the first telegraph, is doubtless more than sufficient: it, however, allowed them to abridge considerably the telegraphic language, and to transmit whole phrases at a time.

The English Telegraph.—M. Chappe's machine was known in England not long after it was set up, and two working models were made at Frankfort, and sent to England, by which the plan and alphabet became known; and its advantages were so obvious, that the British government tried various experiments on telegraphic communication, and at length lines were established from the Admiralty-office to Deal, Portsmouth, and other points of the sea-coast. These machines are upon the construction represented in *fig. 3*, not being made with indicators, like the French, to move upon centres into different positions, but with six octagon boards, each poised upon an horizontal axis, and supported in a frame in such a manner, that each can be placed vertically, and will then appear of the full size; or if they are placed edgewise, as shewn at *d*, the narrow edge alone will be presented, and this at a small distance will be invisible. The boards are turned by means of cranks, *r*, upon the end of the axles, and from these, lines descend into the cabin below, where each has a handle, which is conspicuously marked with the letter or character which will be indicated when the handle is drawn down.

By the changes in the position of these six boards, thirty-six changes may be easily exhibited, and the signal to represent any letter may be made. By certain positions, a variety of other things may be signified, according to the will of the two persons employed at the two extreme posts in making the signals. Thus, one board being in a horizontal

position, and the others shut, or in a perpendicular situation, may denote the letter *a*; two boards only being in a horizontal position may give the letter *b*; three in the same manner, the letter *c*, and so on. As there may be made as many changes with these boards as with the same number of bells, the letters of the alphabet may be made with ease, and a sufficient number of signals may be formed for extraordinary purposes.

This number of changes is sufficient; for as this telegraph is intended to convey information by representing the successive letters of each word, a greater number of changes than would express all the essential letters of the alphabet, the numerals, and three or four more signals, to signify attention, repeat, period, error, &c. would be only embarrassing, and liable to error. It is a good system to spell every word, rather than attempt to communicate entire words or sentences, as by keeping always to one system, mistakes are avoided. The communication is in itself so rapid, that it is more important to attain certainty in the operation, than to make any sacrifice for the sake of dispatch.

This telegraph was judiciously contrived to have a sufficient number of combinations, without having more than necessary. Five boards would have been insufficient, and seven more than were necessary. But there are several serious objections to it: the form renders it too bulky to admit of being raised to any great height above a building; and after all, the boards are less evident to the eye at a distance than the indicators of the French machine. The stations must, therefore, be nearer together, to render the bars of the frame visible as well as the boards. Neither can this telegraph be made to change its direction, but it can only be seen from one particular point. It was found necessary to have two telegraphs at the Admiralty, one for each line, and also at any point of the line where it branched off.

To enable the telegraph to be used at night, the first French telegraph which was set up was furnished with Argand lamps, but the English was never used in that manner. It would have required a great number of lamps; because it would have been necessary to have fixed lamps to indicate the points of the frame in which the boards work, as well as the boards themselves.

These two forms of telegraph, the French and the English, continued in use for some years. The French made frequent changes in the details of their system, though for a long time they preserved M. Chappe's machine; and when Buonaparte assumed the supreme command in France, the original machines were taken down. A number of machines were set up on various parts of the French coast, and were used in some of their campaigns: they were of a very temporary nature, and composed of the simplest materials, of masts and yards, with large balls at the end; the yards were inclined by cords, so as to effect the signals on the same principle as M. Chappe's original machine. About 1806 a new set of telegraphs was established on the whole extent of the coast of the French empire, of which the following description is given by captain C. W. Pasley, in the *Philosophical Magazine*. See *figs. 5 and 6*.

Modern French Telegraph.—Every telegraph consists of an upright post, R, to which are attached three arms, A, B, and C, exactly similar to each other, and each moving upon its own distinct spindle or axis. The axis of one of these arms, A, is near the head of the post R; and the distance between the centres of motion of either of the two uppermost arms, and the centre of the one immediately below it, is rather less than double the length of one arm. The highest of the three arms, A, can exhibit seven distinct

tinct positions, as is shown by the dotted lines A 1, A 2, A 3, &c.; but the other two arms, B and C, can only exhibit six positions each, because they are hidden by the post when in a vertical position. The total number of combinations, or of distinct signals, which can be made by this telegraph, will constantly be three hundred and ninety-one; but as the arm A, when in the vertical position A 4, may appear to be part of the post, R, it is not safe to employ that position, and this will reduce the number of signals to three hundred and forty-two. As only three bodies are employed in this telegraph, it appears very superior to the Admiralty telegraphs used in England, which, by the combination of double that number of bodies, can only make sixty-three distinct signals. Captain Pasley observes, that the mechanism of the French telegraphs just described, must be either imperfect, or the men employed in working them must have been very unskilful, for the signals were made and repeated in an awkward manner, with what seemed to him much unnecessary loss of time. But these defects, it will be evident, detract nothing from its merit as an invention. In regard to the mechanical construction, he could only observe that the arms, which were painted black, and appeared solid at a distance, were made in the fashion of a Venetian blind, in order, it may be presumed, to diminish the action of the wind in bad weather. Each arm had a counterpoise of thin materials painted white, which, unless the observer be very near the telegraph, becomes invisible.

Fig. 5. shews the telegraph in a state of rest, the dotted lines marking the several positions in which the arms can be exhibited. *Fig. 6.* is a specimen of the telegraph at work. *Fig. 7.* shews the construction of one of the arms on a larger scale, DE being the part which is fashioned like a Venetian blind, and EF the counterpoise.

Sir Home Popham's Telegraph at the Admiralty.—The original telegraphs at the Admiralty, with the six boards, have been lately taken down, and a new kind substituted. It is on the same principle with the French, being an upright mast with two indicators, which move upon centres one above the other, in the manner of the last described. The mast is made to turn round on its vertical axis, so as to present its arms successively to all quarters, when required. The mechanism, which is the invention of sir Home Popham, is the best which has ever been contrived, the movements being very simple, and effected by iron spindles and endless screws, so that the indices below are certain to accompany the indicators exactly in their movements, and place them precisely in their required positions, which cannot be done by the old machinery with cords, because they are liable to expand and contract by wet or dry weather. The machinery for this set of telegraphs was constructed in the most substantial manner by Mr. Maudslay in 1816. (See *figs. 8, 9, and 10.*) LM is a tall mast of an hexagonal form, framed up from six fir planks put together at the angles, and bound by iron hoops at different places, so as to be hollow within. The lower end, L, terminates in a pivot, and the mast is retained in a vertical position by a circular collar at O, which embraces it, and is supported in the roof of the building. The two arms, PM and QR, are moveable upon centres, one at the top of the mast and the other half way down. When the arms are placed in a vertical position, they shut up within the hollow of the mast, so as to be entirely concealed; and for this purpose, two of the six sides are cut away at the upper part, so as to leave an opening through the mast of sufficient width to admit the two arms to work in it. To communicate motion to the arms, a small toothed wheel is fixed upon each arm at the centre of motion, and close to the side of the arm. The

teeth of these wheels are actuated by endless screws or worms, formed on the upper ends of the long spindles *de* and *fg*, which descend down to the bottom of the hollow mast, and have small bevelled wheels upon them, which are actuated by wheels of similar size, fixed on the ends of short horizontal spindles, which have handles, *p, q*, applied at the extremities. (See *fig. 11.*) By turning these handles, motion is given to the vertical spindles *d* and *f*; and by means of the endless screws upon the upper ends of them, the wheels at M and R, on the centres of the arms, are turned round, and the arms are put into any required position. But in order that the people below may at all times know exactly what positions the arms stand in, two dials, *m* and *r*, are formed on the lower part of the mast, the upper one, *m*, being for the upper arm M, and the other, *r*, for the lower arm R; and each dial has an index or hand, which turns round with a motion exactly corresponding to the motion of the arms. For producing this motion, the axle of each hand or index has a small toothed wheel, *s* or *t*, (*fig. 11.*) fixed upon it in the middle; and an endless screw is formed upon the upright spindle to work in the teeth of the wheel. The wheels upon the centre of the arms, and those upon the axes of the indices; have the same number of teeth; and as every turn of the spindles and screws will move the wheels round one tooth, the angular motion of the arms, PM and QR, and the hands, *m* and *r*, will in all cases be the same.

The dials are each divided into eight, corresponding with the eight positions in which the arms are to be exhibited: *viz.* pointing vertically; 1st, upwards; and 2d, downwards: pointing horizontally; 3d, to the right; and 4th, to the left: pointing upwards at an inclination of 45 degrees; 5th, to the right; and 6th, to the left: pointing downwards at an inclination of 45 degrees; 7th, to the right; and 8th, to the left. But of these eight positions, only the four last are made use of to represent characters; because, in the two vertical positions, the pointers enter within the mast, and cannot therefore be seen whether they are pointing upwards or downwards: the horizontal positions of the arms are reserved for the necessary signals of preparation, &c. Each arm, then, has four positions, in which it will express different signals; and these positions are all made with the pointer, at an inclination of 45 degrees from the horizontal line.

These signals either express the letters of the alphabet, or the numeral characters, according to previous arrangement, which must be made known by exhibiting a preparatory signal, before the communication is begun. The signal to prepare for receiving letters is the lower arm extended horizontally to the right; and for the numerals, both arms are extended horizontally to the left.

The upper pointer, PM, used by itself, at an elevation of 45 degrees, denotes,

- A, or 1, when pointing upwards to the left.
- B, or 2, when pointing downwards to the left.
- C, or 3, when pointing upwards to the right.
- D, or 4, when pointing downwards to the right.

The lower pointer, QR, used by itself, at an elevation of 45 degrees, denotes,

- E, or 5, when pointing upwards to the left.
- F, or 6, when pointing downwards to the left.
- G, or 7, when pointing upwards to the right.
- H, or 8, when pointing downwards to the right.

It is easy to conceive, that, by repeating all these positions with both arms exhibited together, instead of singly, various combinations may be made, which are sufficient

TELEGRAPH.

ficient to express all the remaining letters, and some other necessary signals.

The dial for each arm is double; that is, a dial is fixed at each side of the mast, and the axles of the indices or hands proceed quite through the mast, so as to have a hand at each end. These dials are not numbered exactly similar to each other, but are reversed; and the two indices on the opposite ends of the same axle, though they point in one direction, do not indicate the same numbers on the two dials; because each dial is adapted to indicate the meaning which the different positions of the arms will have, when the telegraph is viewed on that side to which the dial faces.

For when a signal is made, that arm which projects from the right-hand side, if the telegraph is examined on one side, will project on the left hand, when the telegraph is viewed on the other side.

It was before stated, that the telegraph can be turned round, so as to present its arms to any direction. This is done by the pivot, L, at the lower hand; but to hold it fast in the desired direction, a circular iron plate is placed on the floor, with holes in it; and a bolt, W, is fitted into two eyes, which are fixed to the axle of the mast. The point of this bolt drops into any of the holes in the plate, and thus holds the mast firm; but if the bolt is lifted up, to draw its point out of the holes, it can be turned round. The arms are made with boards, like Venetian blinds; and each has a piece of cast-iron at the opposite end, to counterpoise the weight, and make the arm move freely into all positions.

Since the telegraph has been brought into actual use, its great utility has been obvious; and many ingenious persons have studied the means of simplifying the methods of representing the signals, with a view to obtain the greater facility and rapidity of communication. This would enable us to avoid the danger of mistakes, by being able to repeat the whole communication several times, which at present is tedious. Many of these contrivances display great ingenuity; but it appears to us, that the defect or difficulty of communicating detailed intelligence by means of telegraphs, arises from the complicated construction of all the languages at present in use, rather than from any defects in the machines, which have been proposed to exhibit the symbols; and that to perfect telegraphic communication, it would be necessary to invent a new and more perfect language, which would be a most valuable acquisition, to facilitate all other modes of communicating ideas.

All languages originated in a very rude state of society, and were at first limited to the expression of very simple ideas. As men advanced in civilization, they found the necessity of increasing the number of their words; and to enable them to express more complex ideas, compound words were occasionally introduced; but, in all cases, knowledge must have made a considerable advance, before any arrangement or classification of words was imagined: because the necessity of any grammar would not be discovered, until the number of words were so multiplied, as to render the use of them troublesome, and liable to confusion. Before a system of grammar was established, no improvements could be made in a language, except by the addition of new words; and every such addition must have introduced new difficulties in the use of the language. Even when a system of grammar is completely established, as is now the case in all the languages of civilized nations, the number of words which were invented, or introduced without any system, is so considerable, as to prevent that perfection of expression which might be obtained, if the language had been wholly constructed in an advanced stage of society. There is no doubt but a new language might

be contrived, which, with a very small number of words, compared with any of the known languages, might express all ideas in a much more expeditious and definite manner than they do. In oral communication, this defective construction of language, and the want of precision, is little experienced, unless by those who begin to learn a foreign language; because the extreme rapidity of expression enables us to amplify and enlarge upon any subject, so as to elucidate any words or phrases which are not directly applicable to the expression of an idea to be communicated, or which are at all indefinite. In writing or reading, the deficiency of language is more observable, from the greater difficulty of expression and communication. But when we attempt to converse by signals, we experience in its full force the great complexity of language, and find that it becomes a tedious operation to represent a sentence clearly by signals, which is spoken or written in a moment; and this must continue to be the case, even if the mechanical operation of exhibiting the signals is reduced to the utmost possible simplicity. As no such scientific language as that which we hint at has been perfected, we must content ourselves to find the best means of communicating our ideas by signals, which shall indicate the letters and words of our present languages: and this may be done in two ways; first, by characters or signals, which shall either express the letters of the alphabet, or words, or, in some cases, complete sentences. The other method is to exhibit signals, which shall indicate numbers; and these numbers can be translated into words, by means of a dictionary in which every word is numbered. The telegraphs which we have described are of the former class, and we have explained the manner of using them; but the latter kind requires a greater variety of signals, because they must be capable of making as many signals as there are words in the language in which the communication is intended to be made. There is some difficulty in making a telegraph so universal as this requires, otherwise the numeral method has decided advantages, in the convenience with which it can be carried on by means of a common dictionary, alphabetically arranged, and in which every word is regularly numbered from one end to the other. In this any word can be instantly found, by its place in the alphabet; and the number corresponding to it being exhibited by the telegraph, and observed by the opposite party, he can as quickly find out the same word in the dictionary by means of its number.

The numeral method is perhaps the easiest of all others, and may be exhibited by fire and smoke in the simplest manner, without any telegraph or complicated apparatus being made for the purpose.

The meaning of a signal is ascertained by the continuance or disappearance of fire and smoke at a different place. In the day-time, the smoke on a particular hill may give notice to an observer on the next hill, that a communication is to be made: he of course will answer it by smoke, to shew that he is upon his watch. The smoke will then disappear on both hills, by a cover being placed over the fire; which, being taken off and put on again repeatedly, will shew a succession of clouds of smoke rising at proper intervals in the air. The observer notes the number of times that the smoke rises without a considerable interval, suppose three times; and he then writes down the number 3. After a more considerable interval, determined on by the parties, the smoke rises again, we will suppose four times; he writes down the number 4. He has now the number 34 to communicate by signals to the next post. At night this is done by a successive appearance and disappearance of fire.

As the number denoted by the successive appearance of
E c 2 smoke

Smoke or fire, or firing of guns, may, if it is a large number, be liable to mistake, a learned professor in Germany proposed to shorten the numbers employed, by using a quaternary instead of the decenary arithmetic. Thus, according to his system, the units were to be placed as in common arithmetic; a figure in the next place, to the left hand, instead of denoting the number of tens, was a multiple of 4, denoted by the figure, that is, it denoted the number of fours to be expressed; in the third place, the figure denoted the number of sixteens instead of hundreds; and the fourth place of figures would be sixty-fours instead of thousands; and so on. *E. gr.* To write down 95, he placed his figures thus: 1133; the 3 in the place of units denoted 3, the next 3 denoted 3×4 , or 12; the third figure, 1, denoted 4×4 , or 16; the next figure, 1, denoted $4 \times 4 \times 4$, or 64; consequently 1133, in the quaternary arithmetic, was equivalent to $64 + 16 + 12 + 3 = 95$ in the common decimal numeration. The advantage proposed by thus changing the figures was, that in making the signals 95, there must be fourteen firings, or appearances of smoke, which, in the other mode, is done by eight firings. In this arithmetic, a greater number than four never appears; and there is less danger in miscounting so small a number. Some of the numbers in the dictionary must be devoted to the single letters of the alphabet, as it is by means of them alone that proper names can be made out.

Mr. Edgeworth, who, we believe, first introduced the numeral system of communication, gives the following account of its advantages, in point of secrecy, over the alphabetical method, which is a great object in telegraphic communication. Although the alphabet may be varied at pleasure, and any arbitrary signs employed, yet these are possible to be deciphered by rules which depend upon the usual arrangements of letters: thus, for instance, a single character being exhibited as a word, must, in the English language, be either A or I. The proportion which exists between the number of words of one, two, three, or any greater number of letters, can be classed in catalogues, and from these the monosyllables of any cipher are easily obtained; and from the letters of these monosyllables, the letters of longer words are discovered. By similar rules, some of which are very ingenious, and depend upon the philosophy of language, any alphabetical cipher may be easily unfolded. (See CIPHER.) But these rules, excepting a few of them, are useless, when ciphers are employed to denote entire words; and the most obvious mode of discovery may be avoided, by omitting those common words which occur so frequently in every language, as *the, and, that, to, &c.*; and even supposing that, from its frequent recurrence, any word should be discovered, no progress can be made from such data, for the cipher of any word is an isolated fact which leads to nothing farther.

Suppose the knowledge of any particular vocabulary should fall into hands for which it was not intended, a slight change in the numeration, without any actual change of the figures, would prevent discovery: for instance, suppose it is settled between the parties, that 6, or any other number, is to be added or subtracted from the numbers which are exhibited before referring them to the vocabulary. The advocates of the numeral system state, that a letter can be communicated much quicker by signals which express words, than by signals which express only letters. Words may be forwarded as fast as they can be looked out in a dictionary, and even faster, whilst only an equal number of letters could have been communicated by the alphabetical mode. Another alleged advantage resulting from the use of words in the telegraphic correspondence is, that the words of the same meaning in different languages having the same number attached to each, a correspondence could be carried on from one language into

another, which, though not grammatically correct, yet would be sufficiently intelligible. Proper names must be spelt, which may easily be done, every letter having a corresponding number.

Mr. Richard Lovel Edgeworth, in the Transactions of the Royal Society of Ireland, vol. vi. p. 125, has described his telegraph, which is simple, and admits of very numerous combinations: it is intended to represent numbers to which words may be referred.

The machinery consists of four indices or pointers, each capable of revolving on a centre or axis, so as to assume different positions. The shape of each pointer is that of an isosceles triangle, of which the base is rather less than half the perpendicular. The four pointers are placed in a row, as shewn by *fig. 12*, and, as in common numeration, the right hand represents units; the second from the right, tens; the third, hundreds; and the fourth, thousands. It is easy to distinguish whether a hand moving vertically, points perpendicularly downwards or upwards, horizontally to the right or left, or to any of the four intermediate situations: this produces eight positions, which can be made by each pointer; but of these eight positions, seven only are employed to denote figures; the upright position of the hand or pointer being reserved to represent 0, or zero. The figures thus indicated refer to a vocabulary, in which all the words are numbered. Telegraphs of this kind, which are to be fixed at permanent stations, which may be seen clearly with tolerable glasses at twenty miles distance, are to be mounted on stone or wooden pillars, sixteen or twenty feet high; four of which must be solidly erected in a row; and on the top of each a moveable circle or platform turns horizontally upon a centre, in the manner of a moveable windmill head. Across the platform an axis lies horizontally, and carries the arm or pointer, fixed vertically at one extremity of the axis, whilst, at the other end, are eight handles to turn the pointer round by. The handles are fixed in their different positions by a catch or alid. By means of the platform, the pointer may be turned to any part of the compass; and as one side of it is painted black, and the other white, either side may be employed, as the colour of the clouds, or the situation of the place, may require.

In managing a correspondence by these machines, it is necessary to have certain signals established; nor are these signals merely arbitrary; it is absolutely necessary that they should be made by the two external pointers of the row, *viz.* units and thousands; or by the two internal pointers, *viz.* tens and hundreds; else they could not be repeated by the intermediate stations without confusion; because, in the middle stations, that pointer which represents thousands, when conveying a message eastwards for instance, must, when an answer is returned to an opposite direction, represent units. The same change will take place between the pointer that denotes hundreds and tens.

When any communication is to be commenced, the pointers that denote thousands and units are to be whirled round till the same is done at the corresponding station. When this signal has been answered, the person who gave it proceeds to send his intelligence. As soon as he begins, the pointer of hundreds at the opposite station is turned to 2, and kept in that position till the word is made out from the vocabulary; the pointer is then turned round to 0, or zero. The person who is speaking, when he perceives by this signal that he is understood, turns all the machines to 0, which is always to be done at the end of every word.

When all his machines are in this position, his correspondent again turns his pointer belonging to the place of hundreds to 2, to shew that he is ready to receive the intelligence, and

TELEGRAPH.

it is to remain there till he receives another word, and so on, till all that is meant to be said is finished: the pointers of *thousands* and *units* are then to be vibrated backwards and forwards, with the points downwards, like pendulums, till the same is done at the opposite station.

If any interruption takes place on either side from a cloud, or shower, or any accident, it is to be indicated by vibrating *thousands* and *units*, with their points upwards; which signal must be repeated from the opposite station; and whoever has made the signal of interruption, must make the signal of recommencement, when he is ready to proceed. This signal is by vibrating *hundreds* and *tens*, with their points upwards, and when this is answered, (but not before,) the business may proceed. It should be observed in general, that every signal should be acknowledged by the party to whom it is addressed.

The vocabulary corresponding with the numbers denoted by this machinery is composed of a large book, *fig. 13*, with mahogany covers, framed, to prevent them from warping. Its size, when opened, is 47 inches by 21; it consists of 49 double pages, that is to say, each sheet is folded in the middle, and when it is opened forms one page.

The book is divided into seven parts by thin slips of mahogany, which serve to open it easily at each of these divisions, every one of which contains seven pages, and each page forty-nine words, No more than forty-nine words are contained in each page, because the numbers 8 and 9, and zero, are not admitted. This omission arises from the structure of the machinery, which points only to seven numbers, reserving 0 for a point of rest, at which point the hands indicate nothing. In every hundred, therefore, only forty-nine numbers are used; and in every thousand, only seven hundreds are counted. Each division of the book, separated by the mahogany rulers, contains all the efficient numbers in seven hundred. Each of these rulers projects beyond the sides of the pages, and is numbered in succession from 1 to 7; and they are so placed

below one another, as to permit the numbers on all sides of them to be seen at once, as in the figure.

When any number of thousands is pointed out, it can, by means of these rulers, be immediately selected: the series of seven pages, which one of these rulers opens, is cut, like the alphabet of a ledger, at the edge in seven divisions. By these means, the page containing the hundred which is wanted is instantly found. In the page thus obtained, the tens, from 10 to 70 inclusive, are divided from each other, so as to be instantly distinguishable, and the units under each division are in like manner easily selected.

The following is a specimen of seven lines of the first page, and though it is but one-tenth of the real size, it is sufficiently distinct. Its contents are divided into eight classes, the words in each class being numbered downwards, from 1 to 77, omitting all cyphers, or zero, and all eights and nines. When once the class required is ascertained, any number in the page can be found immediately. As for instance, the reader will easily select Class VII. N° 11, Class IV. N° 15, and so of the rest. Nothing remains to be explained but the manner in which the class in each page is pointed out by the machinery. For this purpose, before the pointers are turned to any set of figures, the pointer that represents thousands is turned to the class that is wanted, and as soon as the correspondent answers this signal, thousands is returned to 0. Then all the pointers are moved to the places which denote the figures required for any word or sentence. When the class is thus ascertained, an index, which slides on the mahogany cover of the book, is set to the column belonging to this class. When an observation is made, the number of thousands can be opened by the ruler. As soon as it is read off by the telescope, the number of hundreds is opened by the pages, where they are cut away, and the number of tens and units is seen on the page. As the pointers are moved in succession from thousands to units, the different divisions of the book can be opened as fast as the pointers are moved.

Specimen of the Vocabulary belonging to Mr. Edgeworth's Telegraph.

The principal objection to Mr. Edgeworth's machine is, that it would be of a vast size, and each pointer would require a man to work it. He describes, at the end of his paper, a portable machine, which is made of spars and poles jointed together, and braced by cords. We think the second kind of French telegraph, which was set up between Landau and Paris, would answer the purpose very well: it has five indicators, and the movements are made by machinery in the house below.

Major C. Le Hardy, in the Transactions of the Society of Arts for 1808, vol. xxvi. has described a telegraph which is well adapted for exhibiting signals which shall indicate numbers. It has four indices or pointers, each consisting of

a long arm, carrying a square index-board or pointer at the extremity. One of these pointers represents units; the second, tens; the third, hundreds; and the fourth, thousands. All the four indices move on a common centre by the machinery; and to distinguish them one from another, each board is placed at a different distance from the centre of motion, so that in their motion they describe four circles of different radii. The position of the arm, with respect to the horizon, is made to indicate the number which is to be expressed by each index respectively, and there are ten different positions for each, answering to the numeral characters.

To identify these ten positions, a large frame is fixed close behind the pointers, parallel to the plane of their motion; and

and this frame supports ten radial bars, which diverge from the common centre of motion. The radii are again intersected by other bars, forming four concentric arcs of circles, each corresponding in radius with the length of one of the four pointers or signal-boards. By means of the radii, the positions of the pointers, and their corresponding numbers, are read off, whilst the arcs serve to distinguish the different pointers of units, tens, hundreds, and thousands, because they always shew the length of the arms from the centre. By this machinery, 10,000 can be exhibited; and for higher numbers, there are two square signal-boards, which can be turned so as to be invisible or visible at pleasure; one represents 10,000, and the other 20,000, and both together 30,000, either of which numbers is to be added to the number shewn by the arms, according as these signal-boards are exhibited. By this addition, this telegraph can exhibit as high as 40,000.

The frame with radial bars is a good method of reading off the exact position of the arms; and it is so much more certain than trusting to the eye alone, that by its aid the arms may be shewn in a much greater number of positions; still, if each arm is distinctly capable of exhibiting ten signals, it will be sufficient for the numeral method. Mr. Edgeworth's pointers, as we have seen, were only capable of eight positions for each; and this obliged him to mutilate the system of numbers, by taking away all the eights, nines, and zero.

The dial-plate of a clock has been proposed as a model, and would make a most excellent telegraph, as it might exhibit 144 signs, so as to be visible at a great distance. The dial should only be divided into six divisions instead of twelve; and this being raised twenty or thirty feet above a building, and the indices and the dial being painted with very distinct colours, would be clearly visible. The dial, if supported on one post, might be always turned to the direction in which the information was to be conveyed.

In the Supplement to the Gentleman's Magazine for 1794, a telegraph is described, which consists of a semi-circle placed in a vertical position on a strong stand. The circumference is divided into twenty-four divisions, which are rendered visible by circular holes cut through the semi-circle. In the centre is an index, which can successively be brought to point out any division, very much in the manner of the dial of a clock. In the night-time each division is to be furnished with a lamp, and the index is made sufficiently broad to eclipse or hide any of the lamps at pleasure to which it is turned, and by this means the letters of the alphabet are to be designated.

Mr. Garnet's Telegraph.—Of all the proposals for making a variety of signals by the different positions of an index or pointer which moves on a centre, the following is the most certain as to the identity of the positions, and hence it admits of the greatest number of signals from each pointer. It has also a farther advantage, that there is no necessity for any frame or dials, like the three last described machines, which, as their divisions are intended to be observed at a distance, must be exceedingly large. The pointer or indicator of Mr. Garnet's machine is the same as the foregoing, and its different positions represent different characters or letters: its length should be two and a half or three feet from the centre, for every mile of distance. The distant observer can find out, and exactly read off these positions by a wire fixed across the eye-piece of the telescope with which he observes, which eye-piece turns round on the end of the tube of the telescope, so as to bring the wire to be parallel to, or correspond with the distant pointer. This is as easy to do as to look through the telescope.

The index or pointer has a small circle fixed on its axis of motion, and turning round with it. This circle is divided into twenty-four divisions, or even more, and each division is lettered with a letter of the alphabet. A fixed index is also provided, to which any letter on the divided circle can be brought by turning the pointer round, and this determines the position of the pointer. Or, instead of an index, the divided rim of the circle may be concealed in a box, with a hole at one side just sufficient to see one letter or division at a time, and then there can be no mistake in setting the pointer. The eye-piece of the telescope is to be made to turn round upon the end of the tube, and is to have a circle fixed upon it similarly divided and lettered. A fine wire is also to be stretched across the centre of the eye-piece in the focus of its lenses; and there must be likewise an index or mark on the telescope, to read the divisions of the circle on the eye-piece. If this circle be likewise enclosed in a box, having a hole to see only one letter at a time, there will be less danger of mistake.

The instrument being correctly adjusted, it is obvious that (the eye-piece of the telescope being turned round till its wire covers or becomes parallel to the distant pointer) the index on the telescope will point out the same letter on the divided circle of the eye-piece, as is indicated by the index and circle of the distant pointer: hence the two parties have the same letter or character presented to them by their respective instruments.

The idea of reading the signals by means of wires on the eye-piece of the telescope is very valuable, and promises many advantages. In intermediate stations, there is always danger of confusion in making signals to parties in both directions; because an arm which inclines towards the right when the telegraph is viewed in one direction, in an opposite direction will appear to incline to the left; and indicate a different thing: hence it is always necessary for the parties to be informed, by a previous signal, in what direction the communication is to be made, that the observers, when they see a signal made, may know whether it is intended for them, or for the next station beyond. Now when the telescope is used, if the circle of each telescope be figured to correspond with the circle of the pointer which is to be observed with it, all signals will become intelligible to any party who observes them.

The Rev. John Gamble suggested a form of telegraph, which consisted of four arms, each ten feet long, and furnished with a circular board at the end. All the four moved upon a common centre of motion, and independently of each other, so that one, two, three, or four, could be exhibited at different degrees of elevation with respect to the horizon, or with respect to each other, so as to afford a great number of signals. One of these was erected in 1803 upon one of the towers of Westminster Abbey, but has long been removed. About the time when telegraphs were first used, this gentleman published a small pamphlet, entitled "Observations and Telegraphic Experiments," which contains some good ideas.

Nocturnal Telegraphs.—In 1801, Mr. John Boaz of Glasgow obtained a patent for a telegraph, which effected the signal by means of twenty-five Argand lamps. These were arranged in five rows, with five in each row, so as to form a square. Each lamp being provided with a blind, with which its light could be obscured, the lamps could be made to exhibit letters and figures, the same as Dr. Hooke's characters, by leaving such lamps only visible as were necessary to form the character. The machine is described in the Repertory of Arts, First Series, vol. xvi. p. 223; and in the Philosophical Magazine, vol. xii. p. 84.

In the Philosophical Magazine, vol. xxix. Capt. Pasley has described a telegraph, which is nearly the same as Mr. Boaz's, but with six lights only; also what is called a Polygramic telegraph.

The Chevalier Edelcrantz has described a machine in the Transactions of the Society of Arts, which is for working the vanes of a telegraph with boards, like *fig. 4*, so that by merely pressing keys, like an organ, and then turning a handle, the required signals shall be made. The telegraph was proposed with nine boards instead of six; but as we consider this form of telegraph decidedly inferior to those with arms moving on centres, we shall not enter into any further description of it.

To conclude, we class the telegraphic art amongst those which are not carried to such a state of perfection as to be incapable of farther improvement: it is much to be wished that it could be so systematized, that the communication of intelligence could be effected with the same ease and certainty as by writing. We are confident of the possibility of this, from having observed the abbé Sicard conversing with his deaf and dumb pupils by making signs of the simplest nature with the hands, in which manner he could communicate his ideas on any subject with more rapidity than by writing.

TELEM, in *Ancient Geography*, a town of Palestine, in the tribe of Judah, towards the extremity of this tribe, along the frontiers of Edom.

TELEMANN, GIO. PHILIP, in *Biography*, one of the greatest and most voluminous musical composers during the first fifty or sixty years of the last century, in Germany. He was born at Magdeburg in 1681, and preceded Keiser as opera composer at Hamburg, for which city he produced thirty-five operas. His compositions for the church and chamber are supposed to be more numerous than those of Alessandro Scarlatti. In the year 1740, his overtures on Lulli's model amounted to six hundred.

This composer, like Raphael and some other great painters, had a first and second manner, which were extremely different from each other; in the first he was hard, stiff, dry, and inelegant; in the second, pleasing, graceful, and refined. Telemann, who lived to a great age, drew up a well-written narrative of his own life, in the early part of which he was an intimate acquaintance and fellow-student with Handel.

The list of Telemann's printed works, inserted in Walther's Musical Lexicon in 1732, amounted to twenty-nine; and in Gerber's Continuation of Walther, fifteen or sixteen more are specified. But still double the number of those printed were long circulated in manuscript from the music-shops at Leipzig and Hamburg.

The best account of Telemann's professional merit as a composer, was published at Hamburg immediately after his decease at 85, in 1767, by professor Ebeling, an excellent musical critic, a friend of Emanuel Bach, a man of a refined taste, sound judgment, and a perfect acquaintance with the merits and various styles of the great musicians of his country.

TELEMBO, in *Geography*, a river of South America, which joins the Patia, 8 miles N.W. of Baracoas.

TELENGUTES. See TELEUTES.

TELENTO, a town of Persia, in the province of Laristan, on the sea-coast; 10 miles S.W. of Congo.

TELEOLOGY, formed of *τελος*, *end*, and *λογος*, *discourse*, the science of the final causes of things. This is an ample and curious field of inquiry, though pretty much neglected by philosophers.

TELEPHANES, in *Biography*, a celebrated performer

on the flute in the time of Philip of Macedon. According to Pausanias he was a native of Samos, and had a tomb erected to him by Cleopatra, the sister of Philip, in the road between Megara and Corinth, which was subsisting in his time. The epitaph upon this musician, which is preserved in the Anthologia, equals his talents to those of the greatest names in antiquity.

“Orpheus, whom gods and men admire,
Surpass'd all mortals on the lyre:
Nestor with eloquence could charm,
And pride, and insolence disarm:
Great Homer, with his heav'nly strain,
Could soften rocks, and quiet pain:—
Here lies Telephanes, whose flute
Had equal pow'r o'er man and brute.”

Telephanes was closely united in friendship with Demosthenes, who has made honourable mention of him in his harangue against Midias, from whom he received a blow in public, during the celebration of the feast of Bacchus. As this was a kind of musical quarrel, we shall relate the cause of it.

Demosthenes had been appointed by his tribe to furnish a chorus, to dispute the prize at this festival; and as this chorus was to be instructed by a master, Midias, in order to disgrace Demosthenes, bribed the music-master to neglect his function, that the chorus might be unable to perform their several parts properly before the public, for want of the necessary teaching and rehearsals. But Telephanes, who had discovered the design of Midias, not only chastised and dismissed the music-master, but undertook to instruct the chorus himself.

TELEPHIASTRUM, in *Botany*, Dill. Elth. 375, so called by Vaillant, from its resemblance to *Telephium*. See TALINUM.

TELEPHIOIDES, Tourn. Cor. 50. t. 485. Dill. Elth. 377. t. 282. See ANDRACHNE.

TELEPHIS, in *Ancient Geography*, a town of Asia, in Greater Armenia, situated in the vicinity of the river Phasis.

TELEPHIUM, in *Botany*, a name adopted from Dioscorides, whose *τελεφιου* the plant we are about to describe was supposed, by Imperato, Clusius, and most authors, to be. Dr. Sibthorp however satisfied himself that the plant of Dioscorides was *Cerintbe minor*, and possibly also the *aspera* of Willdenow. To this conclusion he was led, first, by the authority of the famous old manuscript with drawings, at Vienna; and next, by observing that *C. minor* is particularly common in Greece among vines in the spring, as well as in other cultivated ground, as Dioscorides relates of his *τελεφιου*. The yellow colour of the flowers also answers to his description, which our *Telephium*, in that point, does not, nor did Dr. Sibthorp observe the latter in any part of Greece.—Linn. Gen. 149. Schreb. 201. Willd. Sp. Pl. v. 1. 1506. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 173. Juss. 313. Tourn. t. 128. Lamarck Illustr. t. 213. Gært. t. 129.—Class and order, *Pentandria Trigynia*. Nat. Ord. *Holeraceæ*, Linn. *Portulacææ*, Juss. Gen. Ch. *Cal.* Perianth inferior, of five oblong, obtuse, concave, keeled leaves, the length of the corolla, permanent. *Cor.* Petals five, oblong, obtuse, erect, tapering downwards, inserted into the receptacle. *Stam.* Filaments five, awl-shaped, shorter than the corolla; anthers incumbent. *Pist.* Germen superior, triangular, acute; style none; stigmas three, acute, spreading. *Peric.* Capsule short, triangular, of one cell with three valves, and a central unconnected receptacle, half as long as the capsule. *Seeds* numerous, roundish-kidney-shaped.

Eff. Cl. Calyx of five leaves. Petals five, inserted into the receptacle. Capsule with one cell, three valves, and many seeds.

1. *T. Imperati*. Green Orpine. Linn. Sp. Pl. 388. Willd. n. 1. Ait. n. 1. (*T. legitimum*; Clus. Hist. v. 2. 67. Ger. Em. 520. *Telephio di Dioscoride*; Imperat. Hist. Nat. 662.)—Leaves alternate.—Native of Switzerland, Italy, and the south of France. A hardy perennial, kept in our botanic gardens, flowering in summer. Numerous decumbent, round, herbaceous, leafy stems, a span long, but slightly branched, spring from the crown of the root, spreading in all directions. The leaves are scattered, nearly sessile, obovate, entire, smooth, glaucous, rather succulent, an inch long, more or less. Cymes terminal, solitary, convex, of numerous smooth flowers, with white, or pale flesh-coloured, petals.

2. *T. oppositifolium*. Barbary Orpine. Linn. Sp. Pl. 388. Willd. n. 2. (*T. myosotidis foliis, amplioribus, conjugatis*; Shaw Afric. n. 572. f. 572.)—Leaves opposite.—Found by Shaw in Barbary. Nothing is known of this species but from his rude figure, and short description. The leaves are elliptic-oblong, above an inch in length; the lower ones stalked. Tops of the flowering branches recurved, as in the *Helioscopium*. Petals small. Capsules of three valves, with many seeds; so that there seems no doubt of the genus.

TELEPHIUM, in Gardening, furnishes a plant of the small hardy perennial kind, of which the species usually cultivated for garden use is the true orpine (*T. imperati*).

Method of Culture.—This plant is increased by sowing the seeds in the autumn or spring, in dry light mould, either where the plants are to remain, or in beds to be afterwards planted out. They appear in the spring, when they should be kept clear from weeds, and they will flower the following year.

It is also capable of being increased sometimes by offsets, slips, or cuttings, planted out in the spring season.

It likes a dry light soil, in which it grows best and lasts longest. The plants afford variety in the common borders and clumps when placed in the fronts of those parts.

TELEPHIUM, a malignant dangerous ulcer. The term is derived from Teleplus, who was wounded by Achilles, and whose wound, it is said, became before he died a disease of the above kind.

TELEPHORUS, in Entomology, the *NECYDALIS Cærulefcens*; which see.

TELESCOPE, from *τελε*, at a distance, and *σκοπία*, I see, is an optical instrument that enlarges the visual angle subtended by a distant object, and thereby is said to magnify it, so as to render it visible to the eye of an observer. This property of making distant objects appear close to the eye, never fails to excite the surprise of every one who looks through a telescope for the first time; but few, comparatively speaking, have their curiosity fully gratified, as it regards the means by which this wonderful phenomenon is effected. They are told, that the tube through which they look, contains magnifying glasses, or polished specula, which, by a peculiar arrangement, produce the surprising effect they witness, and there the explanation usually ends; but it is our province to give our readers a better account of this astonishing instrument, which we propose to do in a systematic manner, first by giving a short history of its invention and improvements; secondly, by giving a popular explanation of the theory of the dioptric construction, including the doctrine of aberrations; thirdly, by explaining the theory of the cata-dioptric construction; fourthly, by describing the most approved instruments, with reference to

the drawings that represent their figures on their respective stands; fifthly, by shewing how their magnifying powers may be measured by dynameters, and varied by different arrangements; and lastly, by exemplifying their uses in measuring small angles and their corresponding terrestrial distances. But before we proceed further with this subject, we must request our readers to peruse the articles ABERRATION, CATOPTRICS, DIOPTRICS, LENS, MIRROR, REFLECTION, REFRACTION, and SPECULUM, in the preceding volumes of our work, in order that we may not have occasion to repeat what would otherwise have been necessary to be introduced in this place, to render our account sufficiently full, particularly in that part of it which relates to the theory of single lenses.

1. *The History*.—The invention of the telescope, which was one of the noblest that modern ages can boast of, has enabled man to raise his eyes far above the surface of the globe he inhabits, in search of worlds that were invisible to the unassisted eye; and the more perfect his instrument is made, the more celestial bodies he discovers scattered through the infinitude of endless space. Whether this invention was casual, or the offspring of ratiocination, cannot perhaps be positively affirmed from any existing document; but the probability is, that it was in a certain degree casual: lenses of both the concave and convex formation were used separately to assist the human eye, antecedently to the construction of any telescope; and the general belief is, that some accidental placing of two lenses, one convex and the other concave, of different focal lengths, at such distance from each other, that the rays transmitted through them formed a picture on the retina of the eye, led to the discovery that they possessed the wonderful property of rendering a distant body apparently more large, and consequently more near, than it will appear to the unassisted eye, or to an eye using any single lens whatever: this discovery, once made, would obviously lead to the construction of an instrument, in which this simple combination of two lenses would be the basis.

The honour of having constructed the first telescope, which was no doubt of the dioptric or refracting sort, (from *διόπτρον*, a perspective instrument,) has been attributed to various inventors, several of whom may have been equally entitled to the claim of originality, though only one can be considered as the first inventor. We profess not to be in possession of better information on this subject than our predecessors were, and therefore shall satisfy ourselves with the enumeration of those persons who appear to us worthy of being put on the list of competitors for the honour of this noble invention. Mr. W. Molyneux has asserted, in his "*Dioptrica Nova*," that our countryman Friar Bacon well understood the nature of all sorts of optical glasses, and how to combine them so as to form some such instrument as the telescope; and Samuel Molyneux, the son, has affirmed, that not only the invention but construction of a telescope is fairly attributable to Bacon, as may be collected from various Latin phrases in his *Opus Majus*; and Dr. Jebb, who edited this work, adduces a passage from Bacon's manuscript, to prove that he actually applied telescopes to astronomical purposes so long ago as in the 13th century; the friar having died in the year 1294.

The passages to which Mr. Molyneux refers, in support of Bacon's claims, occur in his *Opus Majus*, p. 348, and p. 357. Jebb's ed. 1733. The first is as follows: "Si vero non sint corpora plana, per quæ visus videt, sed spherica, tunc est magna diversitas: nam vel concavitas corporis est versus oculum vel convexitas:" whence it is inferred, that he knew what a concave and convex glass was. The second is comprised in a whole chapter, where he says, "De visione

TELESCOPE.

visione fracta majora sunt; nam de facili patet per canones supra-dictos, quod maxima possunt apparere minima, et e contra, et longe distantia videbuntur propinquissime, et e converso. Nam possimus sic figurare perspicua, et taliter ea ordinare respectu nostri visus et rerum, quod franguntur radii, et flectentur quorsumcunque voluerimus, ut sub quocunque angulo voluerimus, videbimus rem prope vel longe, &c. Sic etiam faceremus solem et lunam et stellas descendere secundum apparentiam hic inferius, &c.:" *i. e.* greater things than these may be performed by refracted vision; for it is easy to understand by the canons above-mentioned, that the greatest things may appear exceeding small, and on the contrary: also that the most remote objects may appear just at hand, and on the contrary: for we can give such figures to transparent bodies, and dispose them in such order with respect to the eye and the objects, that the rays shall be refracted and bent towards any place we please; so that we shall see the object near at hand or at a distance, under any angle we please, &c. So that thus the sun, moon, and stars, may be made to descend hither in appearance &c. Mr. Molyneux has also cited another passage out of Bacon's Epistle ad Parisiensem, of the Secrets of Art and Nature, cap. 5, to this purpose: "Possunt etiam sic figurari perspicua, ut longissime posita appareant propinqua, et e contrario: ita quod ex incredibili distantia legeremus literas minutissimas, et numerarem res quantumque parvas, et stellas faceremus apparere quo vellemus:" *i. e.* glasses or diaphanous bodies may be formed, that the most remote objects may appear just at hand, and contrarily; so that we may read the smallest letter at an incredible distance, and may number things though never so small, and may make the stars appear as near as we please.

Dr. Smith, however, who must be considered as having been a competent judge of this subject, was unwilling to allow the inference, that Bacon actually made a telescope, and conjectures that he only conceived in his mind how such an instrument might be constructed; which, by the bye, is still allowing the invention, though not the construction, to have been his. But be this as it may, we find no further notice taken of any such instrument as a telescope until about the year 1560, when John Baptista Porta, a Neapolitan, is said by Wolfius to have made a telescope; but the description he gave of his invention in his *Magia Naturalis* is so defective, that Kepler declared it unintelligible; neither does it appear that this telescope was used in any celestial observation. Soon after this time, *viz.* in the year 1579, according to the account of Thomas Digges, in his *Stratificos*, his father, Leonard Digges, had learned from a manuscript book of the learned Bacon, how to discover objects at a distance, by perspective glasses set at due angles, when the sun shone upon them; but it is not evident whether the construction resembled that of a telescope or of a camera obscura, nor whether it was of the dioptric or catoptric kind.

According to Descartes, James Metius, while amusing himself with making mirrors and burning-glasses, happened to look through two lenses, one concave and the other convex, placed by accident at a proper distance from each other, and thus discovered the property that such a combination of glasses possesses of shewing objects at a distance; this discovery is said to have been near the end of the 16th century. The same discovery has been also attributed to John Lipperheim, a maker of spectacles at Middleburgh; but Borellus, in his book entitled "De vero Telescopii Inventore," makes Janfen, or Hansen, (Zacharias Joannides,) another maker of spectacles at the same place, the real inventor of the telescope in the year 1590; and there seems to remain

little doubt but that Janfen was entitled to the honour. The account is, that after having arranged the glasses in a tube, this ingenious mechanic halted to present it to prince Maurice, under a persuasion that it would benefit him in his wars; but the secret soon became public, and Lipperheim immediately copied the invention. This first telescope magnified about fifteen or sixteen times, and its inventor viewed with it the spots of the moon, the body of Jupiter, and even saw some small stars above and below his disc, which appeared to move round him, and which therefore must have been his satellites. From this source, it is supposed that Metius gained his information, as well as Cornelius Drebell, of Alcaer in Holland, who afterwards made similar instruments. We may also mention Francis Fontana, an Italian, as one who claimed the honour of this invention in the year 1608; but from what we have already said, of Janfen particularly, he cannot be considered as the first inventor; though it is possible that the report of such an invention having taken place might incite him to devise the means of effecting a similar contrivance. This, it is generally understood, was the case with the famous Galileo, who, when professor of mathematics at Padua, heard it reported at Venice, in the year 1609, that a Dutchman had presented count Maurice of Nassau with an optical instrument, which had the property of making distant objects appear as though they were near; but notwithstanding about twenty years had elapsed since the invention, the means used for producing the wonderful effect were not known; and Galileo, on his return to Padua, in a very few days not only contrived but constructed a telescope, which he presented to the doge Leonardo Donati, and to the senate of Venice, together with an account of the construction and uses which the instrument might be applied to, both by sea and land; for which service it is well known that his stipend as professor was thenceforth tripled. Among other discoveries that were made with Galileo's telescope in the heavenly regions, the four satellites of Jupiter were found by him to revolve round this planet in their respective periods, and were called the *Medicean stars*, in honour of the house of Medici. This discovery took place early in the year 1610, and Galileo, pursuing his favourite study till March, published at Venice his "Nuncius Sidereus," containing an account of all his discoveries, and dedicated it to Cosmo, the grand duke of Tuscany, who, in a letter written by himself, invited the astronomer to quit Padua for an increased stipend, without the labour of a lectureship. The first telescope which Galileo constructed had only a power of three times; his second was six times more powerful; and his third magnified thirty-three times, which, at so early a date, was no contemptible instrument.

Hence Galileo, though evidently not the first maker of a telescope, has been considered as entitled to all the merit that is due to such a noble invention, seeing he had no model before him, nor instructions how to proceed in the accomplishment of his ingenious work. But though Galileo was successful in the construction and uses of his telescope, which was of the refracting sort, with a concave eye-glass, as we shall shew presently, yet it remained for that sagacious mathematician Kepler to explain, on philosophical principles, the *rationale* of that construction. It was he who first explained the nature and effects of both the converging and diverging rays of light, after passing through the respective lenses, and who demonstrated the principles by which new arrangements might be made in the glasses, that would produce a superior instrument. He shewed that in small obliquities of incidence, the angle of incidence exceeds the angle of refraction about three times.

He also first proved, that in a plano-convex lens, parallel rays are made to converge to a point which is distant from the lens just the diameter of the sphere of convexity; and that, if both sides of the lens are equally convex, this point will be at the centre of the circle of convexity. It remained however for Cavallieri to discover and to prove, in cases where the radii of curvature of the two sides of a double-convex lens are unequal, that as the sum of both the diameters is to one of them, so is the other to the distance of the focus: and it may be proper to notice here, that the same rules are applicable to concave lenses, except that the focus is at the contrary side of the glass.

It is remarkable, however, that Descartes, the pupil of Kepler, makes no mention of his tutor's improvements, in the art of constructing a telescope, having been carried into execution for several years after Galileo's was brought into use. It was not till the year 1630, that Scheiner describes, in his "*Rosa Urina*," the plan of substituting a convex instead of a concave eye-glass, as suggested by Kepler, to be used for astronomical purposes, where the inversion of the object is a matter of no importance, but where the increased field of view is of material consequence. The same mechanician soon after adds a second convex glass to his eye-tube, by means of which the objects become erect, which addition was no improvement to the vision, but rather a detriment; and after him, Rheita gave an erect position to objects, by using three similar lenses in the eye-tube instead of two, which greatly improved the vision, without other detriment than the loss of a little light: and because Rheita's telescope was adapted for viewing objects on the earth, as well as in the heavens, it was distinguished by the name of the *terrestrial* telescope, by way of distinction from Scheiner's *astronomical* one. In both these telescopes, as well as in Galileo's with a concave eye-glass, the power is estimated from the focus of the object-glass divided by the focus of the eye-glass, as will be seen hereafter.

The study of dioptrics now became general, and several improvements were offered by different individuals in the construction of the refracting telescope; but among the real improvers must be placed the very ingenious Huygens, who, being well acquainted with the aberration of the rays of light arising from the spherical figure of the glasses, contrived a better arrangement of the eye-glasses than had before been devised. It was however very soon found, that the power of a telescope of any of the preceding constructions, could not be increased by shortening the focus of the eye-glass alone, beyond certain limits, without introducing great indistinctness, arising from the spherical aberrations; and that the best mode of gaining power, without diminution of light and distinctness, is an increase of the focal length, without much increase of aperture of the object-glass; and a little experience shewed, that it is necessary to increase this length in the duplicate ratio of the proposed increase of power: *i. e.* in order to magnify *twice* as much, the focus of the object-glass must be made *four* times as long as that of another telescope that has the same light and distinctness; and for any other power in a similar proportion. The consequence of this discovery was, that different makers began to vie with each other, with respect simply to the length of their telescopes: among these may be mentioned Eustachio Divini at Rome; Campani at Bologna; sir Paul Neille, Mr. Reive, and Mr. Cox, in England; and in France, Borelli and Auzout. The last-mentioned mechanician succeeded in grinding an object-glass of the astonishing length of 600 feet; and it is said, that Hartsocker made them even longer than this.

It will here occur to the reader, that tubes of this enor-

mous length, if practicable, could not be manageable by an observer; and hence we find, that these very long object-glasses were fixed on the top of long poles, or to growing trees, and so contrived as to be capable of adjustment for the axis of vision when turned to different altitudes, agreeably to the required position of the remote eye-glass.

But while the length of the telescope was thus inconveniently increased, and the trouble of making good observations therewith proportionably augmented, it became a question to determine in what proportion the aperture might be enlarged with the increase of focal length of the object-glass. Auzout wrote a paper, and delivered it to the Royal Society in the year 1665, in which he affirmed, that the diameter of the object-glass ought always to be in a subduplicate ratio of its focal length, or nearly so; and accordingly drew up a table of apertures suitable for all focal lengths, from 4 inches to 400 feet: upon which Dr. Hooke very properly remarked, that the same glass may have its aperture advantageously enlarged or diminished, according to the quantity of light proceeding from the object viewed.

While powerful telescopes were thus obliged to be unmanageably long, and obtained the name of *aerial* telescopes, from the circumstance of their having no tubes to be inclosed in, the immortal Newton had his penetrating mind occupied with meditated improvements on the figure and arrangement of lenses, and proceeding, as he always did, on rational principles, discovered, from the elongated and coloured spectrum formed by rays of light passing through a triangular prism, and from experiments calculated to investigate the cause of such an oblong form and coloured appearance, that light is not homogeneous, and that different rays are differently refrangible, when transmitted through the same medium. This grand discovery presented difficulties standing in the way of the improvement of the refracting or dioptric telescope, apparently much greater than those which had previously been discovered, as arising only out of the spherical figure of the glasses; and all hope of success in making short telescopes of great power, and yet with sufficient light and distinctness, but without an admixture of coloured rays, was given up.

Yet to a mind like Newton's, it naturally occurred, that what could not be practically effected by refraction, might probably be accomplished by reflection of the rays of light into a focus, where, as there would be no separation of the colorific rays by a refracting medium, there would be no colour nor elongation of the focal point, arising from any other aberration, than what might be caused by the figure of the reflecting surface; he therefore abandoned his proposed plan of grinding lenses after the figure of some of the conic sections, (for which sir Christopher Wren contrived a machine,) to avoid the effects of spherical aberration in dioptric telescopes, and turned his mind to the improvement of catoptric or rather cata-dioptric telescopes, which had been previously proposed to Descartes by Merenne, and actually constructed by James Gregory of Aberdeen. The composition for the best metal for reflection, and the mode of grinding and polishing, as proposed and practised by Newton, we have already detailed under our article *SPECULUM*; but as reflecting telescopes have been constructed differently, we will here introduce a short account of the respective differences, before we resume the remaining narrative of the improvements in dioptric telescopes. The first construction of the reflecting telescope was the Gregorian, and most of the portable reflectors continue to be of this construction at the present day: its large speculum is concave, perforated at the centre, and placed at the interior end of the large tube; and the small reflector is also concave, placed

TELESCOPE.

placed opposite the central hole of the large one, in such an adjustable manner, that the rays, after a second reflection, *cross* one another, and come to the eye-glass in such a way, that an *erect* picture of the object, or rather of the image of the object, is formed on the retina of the eye. In this construction, it has been supposed that the figure of the large concave speculum ought to be truly parabolic, because this is the figure recommended by Newton for his construction; but this conclusion is erroneous; for it is the joint effect of both the specula that must be adverted to in their respective figures, so that the rays may come without aberration to the eye-glass after *both reflections*; and in order to produce this joint effect, the curve of the large speculum must be somewhat *more* than parabolic, *viz.* approaching to hyperbolic, because the small speculum is also concave, and has its separate aberration.

In the Newtonian construction, the large speculum is, or ought to be, truly parabolic, and the small one *plane*, set diagonally at an angle of 45° ; so that the rays, after the second reflection, come to the eye-tube on the *side* of the large tube, and near its aperture: the rays do not *cross* here, but come to a focus at the eye-glass, where the object is represented inverted and well defined, as well as bright; for when the rays fall obliquely on the small reflector, they are almost all reflected without dispersion, which is an advantage that this construction has over the Gregorian. When the Newtonian telescope was proposed to Huygens, he had the candour to acknowledge, which proved to be the fact, that there would not be that limit to the aperture of a reflector, that is prescribed by natural necessity to that of a refractor, and that the power as well as light may be made far to exceed those of the latter.

The next construction of a reflecting telescope was that of Cassegrain, described in the Philosophical Transactions of the year 1672. This differs from the Gregorian only in this particular, that the small speculum is *convex*, and the focus of the large or concave one may be longer than is required in the other, for the same length of tube; the rays do *not cross* after the second reflection, and consequently the object is seen inverted, as in the Newtonian: but here the curve of the large speculum is less than parabolic, in order that the joint effect of both the reflections may be an exemption from aberration. This adjustment of the figures of the metallic surfaces is best understood and accomplished by the first-rate opticians, and is but little known to mere theorists.

Of the Herschelian telescope we shall only say, in this place, that it differs from the Newtonian in no other respect, except in its size and powers, and that the second reflector is dispensed with, the length of the tube being equal to the focal distance of the large speculum, and the head of the observer being consequently placed at the upper end or aperture of the tube; so that, in this construction, as little light as possible is lost from the single reflection, the principal loss being that which is intercepted, on its entrance into the tube, by the head of the observer. The parabolic curve for the face of the speculum is equally proper for the Herschelian as for the Newtonian telescope.

From these short historical notices it will be seen, that Merfenne first suggested the hint for constructing a reflecting telescope, which must have been before the year 1651, when his *Catoptrics* were printed; or, according to Descartes' third and twenty-ninth letters, written in 1639, though not published till 1666, before these letters were written. Gregory, who might or might not have seen Merfenne's suggestion, published an account of his construction in his "*Optica Promota*," in the year 1663; but as he was not

a skilful mechanic himself, it is understood that his telescope was but an indifferent one, and that the theory of his construction was not completely realized to his wish. At this juncture, sir Isaac Newton, who was a good mechanic, as well as mathematician and experimental philosopher, took the subject into his consideration, and, by his successful labours, prevented the invention from falling into oblivion. His proceedings met with interruption from the occurrence of the plague; but about the end of the year 1668, he began his experiments on speculum metal, and, in the year 1672, produced two small reflecting telescopes. In these, the large specula were ground into a spherical concave surface, as being the easiest to execute; but he was aware that the parabolic curve, recommended by Gregory, would be preferable, when it could be accomplished by mechanical contrivances, which he judged to be within the reach of human ingenuity. The result of these labours was communicated to the Royal Society of London; and, through the medium of their secretary, Mr. Oldenburgh, to the ingenious Huygens, who testified his approval of this construction in an account which was published in the *Journal des Sçavans* for the year 1672: and in this way, nearly the whole of Europe became acquainted with the Newtonian construction. In the mean time, Cassegrain, a Frenchman, who had varied Gregory's construction, by substituting a convex instead of a concave small speculum, as we have already stated, in the same journal (*des Sçavans*, 1672), contested the honour of having been the first improver of the original Gregorian telescope; which claim drew from Newton several objections to Cassegrain's construction, that will indeed apply equally to the Gregorian. We have, however, recently witnessed in captain Kater an advocate for Cassegrain's telescope, in preference to that of Gregory, (see *Phil. Trans. of London*, 1813 and 1814,) principally with respect to the brightness and distinctness of objects respectively seen by them; and his conclusion is, that much of the light is dissipated by the *crossing* of the rays in the *focal point*, which is a doctrine waiting for confirmation. In Cassegrain's telescope, the picture of the object itself is viewed by the eye; but in Gregory's, the picture of the image representing the object at the point of crossing is only viewed; which circumstance constitutes the essential difference in the two constructions: and it is very probable that the light proceeding from the image of an object may not be so vivid as that proceeding from the object itself, of which the image may be considered as a less enlightened representation.

It is remarkable that no improvement was made on Newton's small telescopes till about the year 1723, when Hadley presented to the Royal Society a reflecting telescope of Newton's construction, in which the focus of the speculum was 10 feet $5\frac{1}{2}$ inches. Though Newton's were only six inches long each, they were compared to the six-foot refractors, such as were made at that time; but what must have been the public feeling, when Hadley produced his enlarged instrument! This was found at least equal in power to the famous Huygenian refractor of 123 feet; at least, its power and distinctness were equal, though the light was not quite so bright.

Since Hadley's time, the reflecting telescope has experienced considerable improvements from the labours of Mr. Short, Mr. Mudge, the Rev. John Edwards, Dr. Herschel (now sir William Herschel), and others who are our own contemporaries.

But while reflecting telescopes were undergoing their various improvements, and were superseding the use of the long refractors, the idea of correcting both the spherical and

prismatic aberrations was not abandoned. We have already asserted, under our article *CIRCLE*, that Chester More Hall, esq. of More Hall in Essex, so long ago as in the year 1729, constructed telescopes of different glasses; some of which have been preserved, and found, on examination, to be of the achromatic kind, though not known by this designation. But as we are not in possession of any record respecting the invention and mode of constructing such telescope, we do not presume to say that this was the archetype of the modern achromatic instrument; and, therefore, we do not consider it as detracting from the merit of the philosophic optician, who afterwards deduced the principles of the invention from accurate and ingenious experiments, and made known his successful application of them at a time when his claim to originality might have been disputed, if the prior invention had been then divulged.

It was not till about the year 1747 that Euler, not knowing what had been done by Hall, and profiting by a hint that had been suggested by sir Isaac Newton, conceived the plan of constructing an object-glass of two such materials, of different refractive powers, as might counteract, by repeated refractions, the dispersion of the differently refrangible rays, and thus bring all the rays into one focal point, so as to admit of a highly magnifying eye-piece. Accordingly two object-glasses were so inclosed in a box, as to include clear water between them, to be used instead of a single lens; and though the experiment failed of success, the memoir, written by Euler on the occasion, attracted the attention of the late Mr. J. Dollond, mathematical-instrument maker of London, who soon after set about making experiments, as Newton had done, to ascertain if the refractive and dispersive powers of various transparent substances are in a constant ratio, with the view of compounding, which he at length effected, an object-glass that would bring the rays of light transmitted through it to a focal point, without the prismatic aberration.

In the memoir which Euler had written, and which was published in the Berlin Memoirs of 1747, he assumed that the indices of refraction might be expressed by the powers of a certain invariable root, and that the exponents of those powers are proportional for the different rays of light passing through different media. This paper coming to the hands of the ingenious Dollond, excited his attention; and in the year 1753 he addressed a letter to James Short, "concerning a mistake in M. Euler's theorem for correcting the aberrations in the object-glasses of refracting telescopes;" which letter was published in the Philosophical Transactions of the same year; the object of which was to prove that Euler had assumed a hypothesis, as the basis of his calculations, which was contrary to both reason and experiment, or, as Short observes in his accompanying letter, "contrary to the established principles of optics." To this Euler replied, and maintained that his optical principle was a true law of nature; but the practical test of its truth was wanting, the use that it was intended to be put to.

In 1754, the Swedish geometer Klingenthierna took up the subject, which now attracted the attention of various mathematicians, and attempted to prove that the Newtonian principle, opposed to Euler's, is in some extreme cases irreconcilable with natural phenomena, and therefore ought not to be received as a law of nature. Dollond, therefore, thus opposed, had recourse to actual experiment, agreeably to Newton's plan of philosophizing; and, rejecting the proposal of putting water between two menisci, with a view of correcting the prismatic aberrations by a number of refractions, proceeded to institute a regular series of experiments, in order to determine what could be done by the opposite

refractions of different diaphanous media; and as these experiments were the foundation of all the improvements that have followed in the construction of colourless, or what Dr. Bevis denominated *achromatic*, object-glasses of a refracting telescope, we shall here introduce a summary account of them.

In the first place, Dollond contrived to form a hollow inverted pyramid with two opposite sides of glass, as in *fig. 1*, *Plate XXIV. Astronomical Instruments*, and placed in an inverted position, within a triangular and equilateral prism of glass, to rest as represented in the figure. The vessel was then filled with clear water, and a ray of light made to pass through both the water and glass prism: the angle at the junction of the glass plates, closing the vessel, was capable of enlargement or diminution; and the glass sides were made to recede or approach, until an object seen through the water and glass prism was in its true place, *i. e.* until the refraction of the water balanced the opposite refraction of the glass. The result of this experiment proved contrary to what had been expected from Newton's experiments; *viz.* an external object seen through this compound prism was fringed with colours. But to be quite sure that there was no deception in the appearance, a glass prism, formed to an acute angle of only 9 degrees, was substituted, which was also more convenient for the experiment, and then the vessel was closed, as in *fig. 2*, until the opposite refractions balanced each other as before; but still the object viewed through the compound prism was tinged with the prismatic colours. The mean rays in these trials proceeded in a straight line, after quitting the second wedge of water; but the extreme rays were deflected, or turned respectively out from exact parallelism.

After having thus ascertained that equal and opposite refractions of glass and water will not destroy the colours, the author varied the experiment, by altering the wedges of water, till he found that the refraction occasioned by the water must be to that occasioned by the glass as 5 : 4, before the colours will disappear. The next step was to pursue the proportions thus ascertained, in the construction of an object-glass containing water; but after uniting a deep and double convex lens of pure water with a concave one of glass, the object seen through the telescope with this compound object-glass was indeed free from colour, but by no means so distinct as was desired, and consequently the spherical aberration yet remained. This telescope was made in 1757, and served to prove that the separation of the extreme rays, or what has since been called the *dispersive power*, in the case of an union of glass with water, is *not proportioned to the mean refraction*; as sir Isaac Newton had asserted it to be, in the same experiment (see Newton's Optics, p. 112, 3d edit.): consequently the idea must now have occurred of trying other diaphanous substances with different refractive powers, to see what the *dispersion* would be in them. After an interval of some time, during which different kinds of glass were procured, the ingenious and persevering artist found, for the first time in the year 1757, that the *dispersive power* of the crystal or white flint-glass was *greater* than that of the English crown-glass, and also that the power of the latter was very similar to that of the Venice straw-coloured glass. He determined, therefore, to try a wedge of flint-glass, and another of crown-glass, formed to different angles, as in *fig. 3*, until, when reversed, their opposite refractions were equal; which equality took place, when their angles were respectively 25 degrees and 29 degrees; in which case, the sines of half the angles, or the indices of their refractions, were 216 : 250, or nearly as 19 : 22. But though the direction of the pencil of light

was

TELESCOPE.

was now unchanged, as was expected, the compound rays had not all the same divergence. The shape of the wedges was then modified, so that the colours disappeared by a due opposition of their respective dispersions; and when this was effected, the refractive powers of the two wedges were found nearly $2 : 3$; and, consequently, the sines of half their angles, $19 : 33$; which ratio is nearly $4 : 7$. In this situation of the wedges, the rays which enter parallel emerge also parallel, while they are equally deflected from the points of emergence. These results may be obtained very strikingly by an union of four wedges, or pair of compound wedges, as represented in *fig. 4*, where the crown receives the rays first, and where the rays, at equal distances from the central line of union, meet always at the same point. This, therefore, pointed out the construction of a double object-glass, such as is represented in *fig. 5*, in which the convex curve of the crown-glass is to the concave curve of the flint of given qualities nearly as $7 : 4$, or nearly in the ratio of their respective dispersive powers. But to avoid the too great effect of spherical aberration, arising from the quick curves, the single convex lens of crown-glass was made into a double convex, with double the radius of convexity; and also the single concave might be made double, with a similar increase in its radius of concavity, to answer the same purpose as the combination last described. But, in this case, the convexity of one glass would not fit the concavity of the other, so as to come nearly in contact throughout: it appeared necessary, therefore, that while the internal faces fitted each other, the external concavity of the flint-glass should be eight times less, or of longer radius than before proposed, in order to maintain the balance of opposite dispersions; or otherwise, as in *fig. 6*, if the double concave faces of flint-glass remain as above stated, the front convexity of the crown-glass must be five-sevenths of the due curvature, as proposed above; while the inner surface remains in perfect contact with the concavity of the other. In these combinations, the superior refraction of the convex lens, being diminished one-third part by the opposing refractive power of the concave lens, required this convex to be ground and polished to a focus three times shorter than would be required for the same lens used singly; and the option, that is afforded the artist, of varying the curves at pleasure, provided the combined effect of the compound lens shall produce a proper effect in banishing the colours, admits of a modification that will correct the spherical aberration also, in a great measure. Telescopes on this achromatic principle were first constructed in the year 1758, and when their merit was once acknowledged, the great number that the inventor and his successors have had occasion to make, both for sale among their customers, and for exportation, have afforded them the easy means of trying a variety of concave and convex glasses together in succession, before they were finally paired; so that their success not only originated in, but has been continued by, the aid of experiments, which no one but the Dollonds has had the power of executing to so great an extent. See DOLLOND.

Nor was J. Dollond's success confined to the manipulation of object-glasses alone; he had previously contrived and constructed the improved system of eye-glasses, in which object he was followed by his son-in-law, Ramsden.

This improvement consisted in extending the usual number of eye-glasses to five, so systematically arranged, that by dividing the errors of spherical aberration, they reduced their amount to an inconsiderable quantity.

The value of this arrangement will be best understood from his own words, which we will extract from his letter, published in the Philosophical Transactions of the

year 1753. "If any one," says he, "would have the visual angle of a telescope to contain 20 degrees, the extreme pencils of the field must be bent or refracted in an angle of 10 degrees; which, if it be performed by one eye-glass, will cause an aberration from the figure in proportion to the cube of that angle; but if two glasses are so proportioned and situated, as that the refraction may be equally divided between them, they will each of them produce a refraction equal to half the required angle; and, therefore, the aberration being in proportion to the cube of half the angle taken twice over, will be but a fourth part of that, which is in proportion to the cube of the whole angle; because twice the cube of one, is but one-fourth the cube of two; so the aberration from the figure, where two eye-glasses are rightly proportioned, is but a fourth of what must unavoidably be, where the whole is performed by a single eye-glass. By the same way of reasoning, when the refraction is divided between three glasses, the aberration will be found to be but the ninth part of what would be produced from a single glass; because three times the cube of one, is but one-ninth the cube of three. Whence it appears, that by increasing the number of eye-glasses, the indistinctness which is observed near the borders of the field of a telescope, may be very much diminished, though not entirely taken away."

We have given this quotation at full length to shew, that in his adoption of several glasses in an eye-piece, the ingenious mechanic was not entirely indebted to his experiments, unassisted by reasoning and mathematical inferences, and accordingly the Royal Society rewarded his skilful labours with Copley's medal. John Dollond was succeeded in his business by his no less ingenious and industrious son, Peter Dollond, who improved the achromatic object-glass still further, by placing a double concave flint-glass between two convex ones of crown-glass, as in *fig. 7*, and by enlarging the aperture to $3\frac{1}{2}$ inches in a 45-inch telescope; of these, a great number has been manufactured, and several of five-feet focal length. His calculations of the radii of convexity and of concavity were never publicly made known; and perhaps constituted a secret, on which the continuance of his celebrity depended, when the time of his father's patent had expired. The business is now successfully conducted by G. Dollond, the nephew, to whom we are indebted for much liberal information; but at no period had any of the Dollonds an agent in Paris, as is said in the new Supplement to the Encyc. Britannica. For several years from the time of the eldest Dollond's death, the foreign Transactions were crowded with dissertations and memoirs on the combinations of achromatic lenses mathematically determined, and the subject afforded ample scope for the geometrical and analytical researches of an Euler, a Clairaut, and a D'Alembert, as well as for Boscovich, Klingentierna, Kästner, and Hennert: but in this, as in some other speculative investigations, the labours of the profound mathematician have not much benefited the practical advancement of the art to which these labours have been directed; nay, they have tended to keep at a distance from each other the mathematician and the mechanic.

Boscovich's eye-piece, however, may be considered as constituting an exception to the preceding remark, and deserves here to be particularly noticed. According to one of his theorems, an eye-piece free from colours may be composed of two similar lenses of the same glass, provided they be placed from each other just one-half of the sum of their focal distances; which is very similar to the eye-glass now commonly adopted, in preference to a single lens, in the common astronomical refracting telescope, the only difference

ference being, that in Boscovich's the lenses are of equal convexity; whereas, in the common improved astronomical eye-piece, the inner lens has a longer focus than the outer one, in the ratio of 3 : 1, and being both plano-convex, they both have their curved faces turned towards the object-glasses.

From the preceding experiments of the Dollonds, have resulted all the advantages that the achromatic refracting telescopes possess over the long telescopes with simple object-glasses, and which have put them in competition with the best reflectors in the essential qualities of power, light, and distinctness of vision. There is, however, an imperfection, notwithstanding Dollond's great skill and perseverance, which remains yet to be overcome, if it is not invincible, which is, that while the colours occasioned by the extreme rays are corrected with sufficient accuracy by the compound object-glasses, yet the intermediate rays are not perfectly corrected; and if any media can be so modified as to correct all the rays that fall on every point of the surface of the object-glasses, so as to make them unite at the same point in the line of the axis; then, and not till then, will the object-glasses be quite perfect. Peter, the son of John Dollond, who, we have said, succeeded to his father's business, pursued this subject after his father's death; and in the year 1765, communicated to the Royal Society by letter the result of his experiments. He remarks, that when his father had made object-glasses of one convex lens of crown-glass, and of one concave of flint-glass, to be used with convex eye-glasses, it was found that the excess of aberration was in the convex portion of the compound object-glass, and that the equality of the counteracting aberrations could not be carried to any great distance from the centre of the glasses; he therefore attempted, about the year 1758, to make short object-glasses of the same sort, to be used with concave eye-glasses; but it was found, that, as the field of view, in using a concave eye-glass, depended on the aperture of the object-glass, the limits of the aperture were too confined with a double object-glass. This trial led the senior Dollond to a conclusion, which the son took up, and profited by; namely, that the excess of spherical aberration, occasioned by one double convex lens of crown-glass, might be diminished by substituting two plano-convex lenses of similar glass and curves, placed one at each side of the double concave of flint-glass. The senior Dollond had succeeded with this construction when a concave eye-glass was used, and when the compound focus was short; but it remained for the son to complete a long object-glass of this construction, to be used with convex eye-glasses; which he succeeded in doing, first with a telescope of 5-feet focus, and 3 $\frac{1}{2}$ inches aperture, and afterwards with a 3 $\frac{1}{2}$ -feet one of the same aperture, which he invited the Royal Society to see, and which was the prototype of the numerous achromatic telescopes of the same dimensions, which have been since constructed and dispersed by sale through all the regions of the globe.

Among the first achromatic telescopes made by P. Dollond, was one purchased by the duc de Chaulnes, who examined very minutely the radii of the respective glasses, and published an account of them in French measures, which, converted into English inches, will stand thus; 32.4 and 40.8 for the outer convex of crown-glasses; 22.2 and 30.6 for the double concave of flint; and 30.6 with 35.5 for the inner convex of crown-glasses; but as the qualities of the respective glasses are not specified, no useful inference can be drawn for the construction of another telescope, in which the glass of each lens may be of another quality. This telescope, we learn from the present Mr.

G. Dollond, had a focal length of 46 inches: and the five-foot telescopes subsequently made, have each an aperture of four inches: but the largest and best telescope of the achromatic kind ever made by P. Dollond, is that of ten-feet focus, and five inches aperture, lately converted into a superb transit instrument by Mr. Troughton, and placed in Greenwich Observatory. See *TRANSIT Instrument*.

Soon after Peter Dollond's telescopes began to be in repute, namely, in the year 1759, Benjamin Martin, at the same time a mathematician and a mechanic, who had long turned his attention to the construction of telescopes, and described various constructions, published his "New Elements of Optics," a book now, like Edwards's Treatise, extremely scarce, in which he has entered more minutely into the doctrine of both kinds of aberrations, as they relate to practice, than any other author has done, either before or since. He not only followed the steps of J. Dollond in determining by glass wedges or prisms the relative refractive and dispersive powers of different specimens of glass, but ground single object-glasses of several kinds of glass, with tools of the same radius, and then compared the geometrical foci of each with the refracted or real foci, by nice measurements: by this means he ascertained the difference between the focus determined theoretically from the known radius, and the real or practical focus of the refracted rays in each glass by measurement, considering at the same time the distance of the radiant point: and thus he gained, as we shall have occasion to shew more particularly hereafter, the ratio between the sine of the angle of incidence and of the angle of refraction in each separate specimen, which ratio, in a ray passing from air into glass, had been assumed in all former optical theorems as 3 : 2 in all kinds of glass, and consequently the focus for parallel rays had been put equal to radius in double convex lenses, and also equal to the diameter in single convex, without regard to the quality of the glass, with respect to its refractive power. The rectification of the old theorem, founded on the constant ratio 3 : 2, formed the basis of the "New Elements of Optics," in which one half of the difference between the old theoretic and the refracted, or

practical foci was called a , and then $\frac{R}{2a} = F$ with parallel

rays became the basis of the rectified theorems, which we propose to give presently in their proper place. According to these new elements, and from a measurement of the angles of dispersion, or of the coloured spectra contained between the extreme rays, as given by a prism of flint, and another of crown-glass respectively, the ratio of which he determined to be as 5 : 3, he calculated that "the radii of the lenses must have the same proportion as the differences of the sines of incidence and refraction in red and violet rays, in prisms of equal refracting angles of white and crown glass;" and that, therefore, "the radii [or foci] of the lenses must have the same proportion as the angles of dissipation in refractions by such prisms; and, of course, the same proportion as the lengths of the coloured spectra produced thereby." From these considerations the author concludes, that "in all cases of a compound lens for producing vision without colours, the ratio of the radii, r and R , of the concave and convex lenses (when two only are used) must be that of 5 : 3; and that then the ratio of their focal distances for parallel rays will be that of 3 : 2 nearly. The ratio of the foci of two lenses being thus determined that shall make the colours vanish, the longitudinal aberration arising from the respective curves was next considered; and in doing this, care was taken that the comparative foci of the two lenses was not to be altered by an alteration in the curves now to be rectified. By Huygens's

TELESCOPE.

gens's general theorem, the aberration arising from the curves of any lens may be determined and compared; and it being known from this theorem, that the longitudinal aberration is equal to $\frac{1}{3}$ ds of the thickness of a double convex lens of equal radii, a double concave was determined from an equation of this aberration such, that its contrary aberration might counteract the aberration of the assumed convex lens of equal radii; and the numbers thus produced for the radii of the double convex of crown-glass, and of the double concave of flint respectively, were 8.36, 8.36, 10, and 23 inches, in which the focal distances of the two lenses are said to be nearly as 2 : 3. In this combination, the compound focus is stated to be 23.3 inches, and the radius $r = 23$ is contiguous to the convex glass. Other calculations were also made where the radii of the convex lens were unequal, as well as those of the concave, but we do not learn that a good achromatic object-glass, put together agreeably to Martin's calculations, was ever yet constructed. In the instance before us, it is evident that the curve 8.36, coming in contact with the concave 23, must touch it in the middle, and therefore the proportions are impracticable.

While these various improvements in the construction of a telescope were going on, we must not omit to mention that different kinds of micrometers were applied to it successively, by different ingenious men, for the purpose of measuring small angles; by which addition, the science of astronomy has been greatly promoted. Among those promoters of this noble science, may be enumerated Auzout, Gascoigne, Hooke, Le Fevre, Kirchius, Cassini, Fouchy, Hollman, B. Martin, Savery, J. Dollond, Dr. Maskelyne, Ramsden, Dr. Herschel, Smeaton, Rochon, Kästner, Cavallo, Troughton, and Arago, the present astronomer royal of France.

But it remained for the ingenious optician of Islington, C. Tulley, to whom we are indebted for much valuable information on the subject of our present inquiries, to calculate and manufacture, from any two given specimens of crown and flint glass, a double object-glass that shall, generally speaking, be found both achromatic, and also as free from the effects of spherical aberration as art can make it.

After this artist had made himself master of Martin's proposed plan of compounding an achromatic object-glass, he found that the curves calculated for this purpose would not produce their desired effect with any specimens of glass that could be procured; but still he thought that a careful repetition of Martin's experiments might lead to results favourable to his views, when some modification was made in their application. He therefore, in the year 1800, obtained six sorts of glass, differing in specific gravity, and ground them all to the same radius by a tool of speculum metal, that did not much alter its figure by attrition in grinding, and in giving a partial polish: these lenses were fitted successively to one cell, that was received by a tube having an eye-piece at the opposite end, in order that the solar focus of the refracted rays might be the more accurately measured with each glass used as an object-glass of a telescope; and though the polish was imperfect in these lenses, ground and partially polished by the same tool, yet the image of the sun was clearly defined by them. These focal distances, limited by the solar image, were in the next place measured carefully by a nicely divided scale, and were found to differ from one another considerably, as we shall hereafter have occasion to state more particularly: the radius of curvature of the tool was also ascertained with equal care, and found to exceed in length the longest of the focal lengths of the refracted rays. The radius of the tool was then divided by each of the refracted focal lengths, and the quotients were called so many divisors or multipliers, accordingly as the geometrical was

to be determined from the refracted focus, or the contrary. These quotients, therefore, bore the same proportion to unity, that the geometrical focus bore to the refracted focus of each lens, and turned out to be very nearly the same quantities that Martin had determined with glasses of similar qualities, and that he denoted by the expression $2a$ in his rectified theorems. In fact, they were the numbers from which the ratio of the sines of the angles of incidence to the sines of the angles of refraction were accurately determined, as will be explained hereafter. The specific gravities of the different lenses were then taken with a good hydrostatic balance, and were found to increase with their corresponding divisors, but not in a regular proportion. From these experiments a set of tables was constructed, containing in parallel columns, both for crown and flint glass, the specific gravities, varying from 3.466 to 2.428, together with the corresponding ratios of the sines of the angles of incidence and of refraction; and also the ratios of the two curves, that shall produce an assigned longitudinal spherical aberration in any lens; all which calculations are extended from the ratios 1 : 1, 1 : 1.01, 1 : 1.02, &c. in succession, up to 1 : 6, where the aberration is a minimum, as was long ago determined by Huygens: and what is worthy of remark, the French plate-glass, which had the specific gravity lowest, and its divisor only 1.004, and which, consequently, had its refracted focus nearly equal to its geometrical focus, was, in all probability, similar to the glass manufactured at the time when the experiments of sir Isaac Newton were made, from which the original optical theorems were framed. From these tables, our skilful optician takes his curves by inspection suitable for glass of any given specific gravity, such as will suit his tools for telescopes of different lengths; and having as it were the command of the whole range of varying ratios, he can immediately fix on suitable curves for any glass, and for any compound focal length, or even assign a fellow that shall match any practicable lens, convex or concave, that has been previously polished. Such is the facility which this ingenious and persevering optician has attained in the highest branch of his art, whilst, at the same time, his skill in grinding, polishing, and centering his glasses, is not exceeded by any other artist. The principal deviation from Martin's rules, that Tulley found it necessary to adopt in his practice, is the application of a *correcting number* to the calculated or tabulated aberration arising from the figure of the flint-glass, on account of its difference of refractive power, as compared with that of the crown-glass: in order to gain which correcting number in all different cases, he first reduces the geometrical foci of the two separate lenses into the refracted foci by his divisor = Martin's $2a$, and extracts the square root of the cubes of those refracted foci respectively; then dividing the root of the flint-glass by the root of the crown-glass, he gains the *correcting divisor*, by which the calculated aberration of the flint-glass is divided, to produce the *corrected aberration* for the concave lens; which lens must now have its radii determined agreeably to this corrected aberration from the general theorem, or may be taken from the tables to be substituted for the radii that would have been requisite, if the proportional aberration had remained uncorrected. And lastly, that the foci of the separate lenses may be so proportioned to each other, and to the compound focus of both the lenses, which is usually given when a telescope is to be made, the ratio between the focus of the crown-glass and of the compound glass, having been calculated by an appropriate theorem, as will be explained, is tabulated to suit different sorts of glass agreeably to their specific gravities; so that Martin's constant ratio of 5 : 3 is varied according to the variation of the specific

TELESCOPE.

cific gravity, which is assumed as bearing a due proportion to the dispersive power: Thus, when a piece of crown and a piece of flint glass are produced for an achromatic object-glass, the specific gravity is first taken, and then the tabulated numbers, corresponding to these gravities, are taken from the columns of the tables, and the work is put in hand as soon as suitable tools are selected for producing the curves: or rather, when the relative foci are determined, the curves are fixed on in the tables that will suit the aberrations in question, and that can also be produced by such tools as are in use; for the formation of a new grinding tool is a serious undertaking, that the optician will wish to avoid. But after all, the chief practical difficulty remains; the same curves cannot always be worked to be exactly similar, even in the same glass, with the same tools, and by the best workmen; which circumstance leaves the nice calculator, in some measure, under the controul of his materials, and renders final adjustments indispensable. These observations are corroborated both by the candid acknowledgment of Tulley, and by the subjoined extracts, which we beg leave to transcribe from the letters of our estimable correspondent Mr. G. Dollond.

"The perfection of our object-glasses," says Mr. Dollond, "is in a great degree promoted by the great pains we take in selecting those glasses that suit each other the best; and also in adjusting them very carefully: yet that is not every thing that is necessary to produce good object-glasses; they must be correctly worked, and the glasses be of perfect and proper quality.

"With respect to the surfaces used in our various object-glasses, it would be almost endless to enumerate them, as they depend upon, and vary with almost every piece of glass that is used in their formation; and there are some nice points in the method of working them, which I should not wish at present to disclose. Our usual mode of proceeding is, in the first place, to calculate the proportions that are requisite for the kinds of glass that are to be used, and then to select from our great number of tools those that come the nearest to the surfaces determined upon; and it frequently happens that we have not any that will answer, particularly for the spherical aberration. We do not enter into those very nice calculations that would be satisfactory to a theorist; we only aim at something near to what is required; for to practical men, it is always more easy to produce what they wish by practical methods. Mr. Short, the celebrated maker of reflecting telescopes, used to proceed by first making his large metal as nearly correct or parabolical as he could, and then, from a number of small metals, to select, by trial, that which corrected the large one in the best manner.

"In all matters relating to the practice of optics there is much uncertainty, and it frequently happens that, with the very best endeavours, we cannot produce by the same means the same effect, where extreme correctness is required; so that you may very readily conceive, that very exact calculations, however requisite, will not always answer. In a rough way of taking the focal lengths and surfaces of an achromatic object-glass, composed of crown and flint glass of the usual densities, we should say crown 1 : 3 and flint 2 : 3; the outer surface of the crown shorter than that which is next to the flint, and the shortest radius of the flint next to the crown; and the nearer it can be brought without touching in the middle, the more perfect will be the performance; though this will in a great degree depend on the aberrating powers of the glasses used; for sometimes we find it necessary to make the crown nearly of equal radii. The French opticians make the radii of the convex lens very unequal, and place the shortest radius next to the flint; and instead of crown they use Bohemian plate, which is nearly of the same

refracting power, but of a different colour, their flint-glass being of a much less specific gravity than the English.

"The great barrier to further improvement, particularly in the extension of the aperture, is the want of good glass, which circumstance has ever been lamented; and from the excessively increased duties, which act against the improvement of every manufacture, a prohibition is now likely to take place altogether."

In this historical account of the invention and successive improvements of the telescope, we have said nothing about the ingenious experiments of Dr. R. Blair, professor of astronomy in the university of Edinburgh, which were made, with a view to ascertain the dispersive powers of different liquids, about the year 1787, and for this reason, that we consider any telescope of which a liquid forms a constituent part, to be a temporary rather than a permanent instrument. Neither have we given Dr. Herschel's labours so prominent a place in our narrative as they deserve, because we shall have occasion to describe his reflecting telescope, with reference to its appropriate plate, in a subsequent section of our article.

Besides the preceding improvers of the telescope, several persons, chiefly amateurs, have taken out patents, either for alterations in the appendages of this instrument, or for peculiar modes of using them for particular purposes, with a short notice of which we shall conclude this section of our article. On the 4th of April, 1791, Mr. Robert Blair, a surgeon in the navy, took out a patent for securing to himself the advantages to be derived from using a fluid medium, in conjunction with glass, to correct the prismatic aberration in an object-glass of a refracting telescope, agreeably to the experiments previously made on this subject by Dr. Robert Blair, as we have just stated. On the 26th of January, in the year 1799, Mr. Cater Rand, of Lewes in Sussex, took out a patent for "an improved military and naval telescope, for ascertaining distances, and the size and extension of objects, at sight, by means of a new micrometrical adjustment." This micrometrical telescope, however, was nothing more than the parallel wire micrometer, applied to a common pocket achromatic telescope, in which a vernier scale projected from the eye-piece, and indicated the quantity of the measured angle to the professed accuracy of 6"; but how the instrument was kept steady enough without a stand for the use of such a micrometer, is not explained. Mr. Dudley Adams, of Fleet-street, optician, took out a patent, on May 30, 1800, for rendering telescopes more portable; the object of which was to secure the advantage to be derived from using tubes, with slits made in such a way as to make them move smoothly, and yet without shake, within one another. Mr. G. H. Brown, secretary to the Westminster fire-office, in Bedford-street, Covent-Garden, has described, in the 11th volume of the Repertory of Arts and Manufactures, a reflecting telescope, that always lies in a horizontal position; and, receiving the rays of light on an inclined plain mirror, having a central perforation, and placed near the insertion of the eye-tube, reflects them to the large concave speculum, which, by a second reflection, forms the image in the eye-tube. Benjamin Martin constructed a reflecting telescope in this way, which he used in a vertical position for terrestrial objects; and the only difference in the two constructions seems to be, that in Martin's, the main tube was reclined when viewing elevated objects, such as the heavenly bodies, whereas Brown's plain mirror has a vertical motion independently of the main tube. They have neither of them come into common use.

Mr. Manton, gun-smith, of Davis-street, Berkley-square, London, took out a patent on the 23d of January, 1810, for

TELESCOPE.

for securing the use of an exhausted tube, on a supposition that there would be more light when the rays were refracted to a focus *in vacuo*. Mr. Cornelius Varley, artist, now of Newman-street, London, took out a patent for a graphic telescope, for the purpose of delineating drawings from nature, on the principle of Dr. Wollaston's camera lucida, the date of which is April 5, 1811. And on the 21st of May of the same year, Dr. Brewster of Edinburgh, and Mr. Harris, optician, of Holborn, London, jointly took out a patent for a micrometrical, double-image, and coming-up glass, &c. which has its scale of measurement running longitudinally along the tube. This telescope, being on a new construction, will be particularly described hereafter.

2. *Theory of Dioptric Telescopes.*—Before we can properly describe the various constructions of either the refracting or reflecting telescope, it will be necessary to explain the principles on which those constructions are founded; and for the sake of order, we will confine ourselves, in the first place, to the consideration of the elementary principles of dioptrics, so far as they are connected with the theory of the refracting telescope. Among the various writers who have considered this subject, in both a scientific and practical manner, Benjamin Martin stands first in our estimation; and as his "New Elements of Optics," published in 1759, are but little known, by reason of the scarceness of this work, notwithstanding it contains the result of all his theoretical and practical investigations, we shall make no scruple in availing ourselves of his labours, as often as they contribute to the purpose of either illustration or practical application: our aim being, in this article, as in some former ones connected with it, to bring the mathematician and the mechanic into a state of mutual understanding.

We propose, therefore, to avoid as much as possible all abstruse calculations, that have no tendency to produce practical advantages, but to introduce, in as familiar a manner as possible, those mathematical investigations only, which are essentially explanatory. The first and fundamental principle in dioptrics is this, that in all uniform media, such as air, water, glass, &c. "the sines of incidence are in a constant ratio to the sines of refraction" of any homogeneous ray of light, incident on the surface of such refracting medium; which principle was first discovered by Snell, when Huygens had gone no further than to assert, that in small obliquities of incidence, the angle of refraction was about one-third of the angle of incidence. In the glass which Sir Isaac Newton used, the ratio of the sine of incidence to the sine of refraction was found to be 30 : 21, or nearly 3 : 2, in passing out of air into glass: and had all kinds of glass been found equal with respect to their refractive powers, the radius of convexity would, in all cases, have been equal to the focus of a double convex lens of equal radii; which equality may be considered as the basis of all the *geometrical* theorems in optics, that take no account of the difference of the *refractive powers*. But since the difference of the refractive powers of various specimens of glass has become an object of indispensable examination to the optician of modern times, it has become necessary to introduce into each theorem the ratio between the sine of incidence and sine of refraction, whatever it may be found to be by experiment, before the *refracted* focus of any individual lens, depending on the quality of the glass, in some measure, can be determined from the *geometrical* focus depending on the radius of convexity or concavity. As we have demonstrated, under our article REFRACTION, the constancy of the ratio between the sines of the angles of incidence and of refraction of a mean refracted ray; and have also explained how the *geometrical focus* of any lens may be deter-

mined with converging, parallel, and diverging rays, under the term LENS; we will proceed to apply the doctrine arising out of these demonstrations and explanations to our present purpose. "Let DC (*Plate XXIV. Astronomical Instruments, fig. 1.*) be a ray of light incident out of any medium X, upon the surface, HO, of another medium Y, which we will suppose to be more dense than X; and from the point of incidence C, let it be refracted to F, out of its first direction DCM. This refraction may be considered as arising out of the attracting power at the surface of the medium Y, and as acting upon the ray in a perpendicular direction, by which, on mechanical principles, it will acquire some additional force and velocity of motion through the medium Y. Now upon the centre C describe the circle AOPH, cutting the incident ray in D; and drawing the diameter ACP perpendicular to HO, let DL fall perpendicular thereto, and it will be the *sine of incidence*. Let DC or CE represent the space described in a given time in the medium X; and from E draw EF parallel to AB, to denote the acquired force in C: then the motions in the directions CE and EF, in the same time, being compounded, will produce a motion in the direction found by joining CF; for CF will be the space described in the medium Y, in the same time that DC (= CE) was passed over in the medium X, and consequently will be the *refracted ray*; and GI, perpendicular to AB, will be the *sine of refraction*.

"Through F draw NM parallel to HO, and draw KE perpendicular to AB; then will BF = KE = DL be the *sine of incidence*; and in the similar triangles CIG, CBF, we have CG : CF :: GI : BF. Hence it appears that we have the sines of the angles of incidence and of refraction BF or DL, and GI, as the velocities CF and CD (= CG) in the different media inversely, and on this supposition they are in a *constant ratio*; because the velocities are invariable, being produced by the uniform operation of nature. And on the contrary, if the ray FC be considered as passing out of a dense medium Y, into a rare medium X, it will be deflected by the superior force of the medium Y, into the direction CD; making DL : IG :: CF : CD, as before.

"Let us now conceive AMD, in *fig. 2*, to be the curved surface of a refracting medium Y, and B a radiant point in a more rare medium X, from which two rays proceed, and fall upon the curve in the points M and N indefinitely near to each other: these rays will be so refracted as to cross each other in a certain point F; to determine which from the given equation of the curve, the distance of the radiant, and the refractions of the media, is that problem in dioptrics, on which the various calculations and inferences depend. That we may render the solution of this problem intelligible to our readers, let us make the lines CM and CN the radii of curvature, and consequently perpendicular to the curve at the points M and N; upon MF and NF let fall the perpendiculars CG and Cg, cutting FM in S: also upon the incident rays BM, BN, continued, let fall the perpendiculars CE, Cc; and on the centres B and F, describe the small arcs RM, MO; and put BM = *d*, ME = *a*, MG = *b*; the arc MR = *s*, and the arc MO = *t*; and lastly, the sine of incidence CE to that of refraction CG, as *m* to *n*, the radius of curvature being CM = *r*. Then the triangles MEC, MRN; MGC, MON; MBR, QBe, are similar, as is thus evident: if from the right angles RME, CMN, you subtract the angle EMN, there remains the angle RMN = EMC; and if from the right angles FMO, CMN, you take the angle FMN, there will remain the angle OMN = GMC. These tri-

TELESCOPE.

angles are, therefore, *equiangular*, and consequently *similar*. Hence we derive the following analogies for determining the refracted ray MF; viz. ME : MC :: MR : MN;

that is, $a : r :: s : \frac{rs}{a} = MN$.

“ Again, from the triangles MGC and MON, we have

MG : MC :: MO : MN; that is, $b : r :: t : \frac{rt}{b} =$

$\frac{rs}{a}$ ∴ $sb = at$; and so $a : b :: s : t$, or $\frac{bs}{a} = MO$.

And in the triangles BMR, BQe, we have BM : Be (= BE) :: MR : Qe; that is, $d : d + a :: s :$

$\frac{ds + as}{d} = Qe$. But Ce : Cg (:: CE : CG) ::

$m : n :: Ce - CE : Cg - CG :: Qe : Sg ::$

$\frac{ds + as}{d} : \frac{nas + nds}{md} = Sg$.

“ Lastly, the similar triangles EMO, FSg, give MO : Sg :: MF : SF or GF; therefore, MO - Sg :

MO :: MF - GF (or MG) : MF; that is, in symbols $\frac{bmds - aans - ands}{amd} : \frac{bs}{a} :: t : \frac{mddb - aan - nda}{mddb} = MF$, the focal distance required.

“ As the right angles at E and G are both subtended by the same hypotenuse, or right line MC, it is evident that this line is the diameter of a semicircle, MEGC, passing through them, as in *fig. 3*; and if the curve AMD be a circle, then C will be its centre; and when the point M is extremely near to the vertex A, there will be ME = MG = MC, or $a = b = r$. In this case, the theorem becomes $\frac{rmd}{md - nd - nr} = AF = f$; and the point F, or focus of refracted rays, is then in the axis BC produced.”

From this original theorem for finding the simple refraction of a pencil of diverging rays out of a rare into a dense medium, may be derived other theorems for finding the simple refraction out of a dense into a rare medium, and for the refraction of lenses of any of the common shapes, either at the first or second surface. We will subjoin a small table of such of those theorems as apply to glasses of the ordinary construction.

Theorems for one simple Refraction.

Out of Air into Glass		
Rays.	Convex.	Concave.
Diverging	$\frac{m dr}{md - nd - nr} = f.$	$\frac{-m dr}{md - nd + nr} = f.$
Parallel	$\frac{m r}{m - n} = f.$	$\frac{-m r}{m - n} = f.$
Converging	$\frac{m dr}{md - nd + nr} = f.$	$\frac{-m dr}{md - nd - nr} = f.$
Out of Glass into Air.		
Diverging	$\frac{-n dr}{md - nd + nr} = f.$	$\frac{n dr}{md - nd - nr} = f.$
Parallel	$\frac{-n r}{m - n} = f.$	$\frac{n r}{m - n} = f.$
Converging	$\frac{-n dr}{md - nd - nr} = f.$	$\frac{n dr}{md - nd + nr} = f.$

Hitherto we have considered the refraction of a ray at only one surface of a lens; but as every lens has two surfaces, or radii, r and R , it is necessary to carry our investigation farther, and see what theorems can be obtained for finding the foci of glasses of the different shapes, when double refraction takes place, which is the case in all instances of complete transmission. By way of distinction, we will consider r as the radius of the first surface, or that which receives the rays from the radiant; and R as the second surface, or that which is supposed to be turned from the radiant, in all our subsequent theorems. We must now

consider a ray, as MN, in *fig. 4*, coming out of a dense medium Y, after proceeding in a direction towards F, into the rare medium X; but meeting with a spherical surface ND, on quitting the dense medium, is refracted into the direction Nf, to intersect the axis Df, in the focal point f . When two spherical refracting surfaces are near to each other, as AM, ND, in *fig. 5*, they constitute a lens AMND, of which the radius of the curve AM is r , when the radiant is on that side, but that of ND is denominated R ; and the line BADF, passing at right angles through the middle of the lens, is called the axis. Now to find

TELESCOPE.

find the point f , or focal distance Df , of the ray BM , coming from the radiant B , after being twice refracted, *viz.* at M and N , the points of ingress and egress, is the *general problem of dioptrics*.

In solving this problem, our original theorem for simple refraction gives us $m d f - m d r = n r f + n d f$, (making $MF = \phi$), from which equation we deduce this expression; *viz.*

$$\frac{m}{n} = \frac{r+d}{\phi-r} \times \frac{\phi}{d} = \frac{BC}{CF} \times \frac{AF}{AB},$$

which gives this universal canon: *viz.* "the ratio of the sine of incidence to the sine of refraction, is compounded of the ratio of the distances of the conjugate foci B and F from the centre C , and of the ratio of their distances from the vertex A ." This rule being *general*, finds the focus f , after the second refraction at N : for let $Df = f$, the radius $GD = R$, and the thickness of the lens $AD = t$; then we have for the refraction

out of a dense medium into a more rare one, $\frac{n}{m} = \frac{FG}{fG}$

$$\times \frac{fD}{FD} = \frac{\phi + R - t}{R + R} \times \frac{f}{\phi - t};$$

from whence we get

$$f = \frac{n \phi R - n t R}{m \phi - m t + m R - n \phi + n t} = Df,$$

the focal distance required. If we omit the thickness of the lens t , as being inconsiderable, we may reduce the equation into a more

simple form; for we shall have $\frac{n \phi}{m \phi + m R - n \phi} = f$; and

this will give $\phi = \frac{m f R}{n R + n f - m f} = \frac{m d r}{m d - n d - n r}$,

which equation reduced gives

$$\frac{n d r R}{m r d - n r d + m d R - n d R - n r R} = f.$$

But to reduce the number of symbols, let us put $\frac{m-n}{n} = a$, and consequently $m-n = a$, when n is unity,

and then this equation becomes $\frac{d r R}{a r d + a R d - r R} = f$,

and this may with propriety be called the *universal dioptric theorem*, by which the *refracted focus* of a ray may be determined after passing through any lens of a given density, or refracting power.

The theorems in the subjoined Table I. are all derived from the universal theorem thus determined, and will be of great use to the optician to determine the *refracted focus* of any lens, and for any distance of the radiant, which *refracted focus*, with parallel rays, will be always equal to

the true, or nicely measured *solar focus*, where d is infinite; whereas the focus determined from the old theorems in Table II. where the value of a is omitted, is always the *geometrical focus*, determined on a supposition that the sine of incidence is to the sine of refraction in all glasses as 3:2,

in which case $\frac{m-n}{n}$, i. e. $\frac{3-2}{2} = \frac{1}{2}$ invariably, and $\frac{1}{2} r$,

in a double convex lens of equal radii, of whatever refractive power, = f . In order, therefore, to distinguish the focus determined from the theorems in Table I., from those arising from the theorems in Table II., we will always call the first the *refracted focus*; which is that from which the *powers* of a telescope or of a microscope are derived; and the second we will denominate the *geometrical focus*, which is that arising from the simple consideration of the radii of curvature, without reference to the refractive power of the glass, otherwise than as we have stated; but is notwithstanding useful to opticians in the formation of the curved faces of their grinding and polishing tools; for when the curves of a lens of a given refractive power are to be formed, to produce a given refracted focus, as is frequently required in the nicer optical instruments, the refracted focus must first be converted, by means of the value a of its refractive power, into the *geometrical focus*, and then the radii of curvature belonging to this calculated *geometrical focus*, will be proper for the tools of the lens of a given refractive focus. Hence we consider it as a matter of great practical importance, to give, in the same place, two tables, one for finding the *refracted*, and the other for finding the *geometrical foci* of such lenses as are usually applied in either a telescope or microscope of the refracting construction. In all cases where the glass has two radii, the first, as we have said, will be denominated by r , and the second by R .

But before we proceed to tabulate our theorems for both *refracted* and *geometrical foci* of single lenses, we wish it to be clearly understood by our readers, that the practical application of those theorems, and of others to be derived from them, to the purpose of actual construction of achromatic object-glasses, and of achromatic eye-pieces, is intended to be the leading feature of our article; for while volumes have been filled with abstruse calculations, derived from formulae of the most celebrated mathematicians, the results of those calculations have never produced proper data for the use of opticians; more particularly with respect to achromatic object-glasses, which cannot be constructed from any calculations but what are grounded upon experimental examination of the identical specimens of glass that are intended to be used. And we flatter ourselves, that the information we have to lay before our readers on this interesting subject, will be the *first* that has yet been *published* in such a *practical form* as will facilitate the labours of the working optician.

TELESCOPE.

TABLE I.—Theorems for finding the *refracted Foci of Lenses.*

Lenses with unequal Radii.		
Rays.	Convex.	Concave.
Diverging	$\frac{d R r}{a d r + a d R - r R} = f.$	$\frac{d R r}{-a d r - a d R - r R} = f.$
Parallel	$\frac{r R}{a r + a R} = f.$	$\frac{r R}{-a r - a R} = f.$
Converging	$\frac{-d r R}{-a d r - a d R - r R} = f.$	$\frac{-d r R}{a d r + a d R - r R} = f.$
Lenses with equal Radii.		
Diverging	$\frac{d r}{2 a d - r} = f.$	$\frac{-d r}{2 a d + r} = f.$
Parallel	$\frac{r}{2 a} = f.$	$\frac{-r}{2 a} = f.$
Converging	$\frac{-d r}{-2 a d - r} = f.$	$\frac{d r}{-2 a d + r} = f.$
Lenses with one Radius (R) infinite.		
	Plano-convex.	Plano-concave.

Lenses with both Radii (r and R) negative, or double concave.		
Diverging	$\frac{2 d R r}{-d R - d r - 2 R r} = f.$	$\frac{d R}{-d - R} = f.$
Parallel	$\frac{2 R r}{-R - r} = f.$	$\frac{d R}{-d} = f.$
Converging	$\frac{-2 d R r}{d R + d r - 2 R r} = f.$	$\frac{-d R}{d - R} = f.$

TELESCOPE.

As we explained how Table I. is derived from an universal dioptric theorem, we shall explain how the theorems in Table II. are deduced from one fundamental equation, on a supposition that the sines of incidence and refraction in glass are always as 3 : 2. Let LN, in *fig. 6*, represent a convex lens, O *f* its axis, O a radiant point therein, OA a ray proceeding from thence to A, a point in the surface LBN; then if C is the centre of convexity of that surface, CG, drawn through the point A, will be perpendicular to that surface in the point A; CA or CB is the radius, Af the refracted ray, and *f* the point where it meets the axis after the first refraction. Let DB = *d*, CA = R, EB = *t*, the thickness of the lens; and let the sine of the angle of incidence OAG be called *m*, and the sine of the angle of refraction CAf or GAH be called *n*. Now, since the point A is supposed to be very near to the vertex B, OA may be considered equal to OB = D, and in the triangle CAO, we shall have AO to AC as the angle C to the angle O; that is, *d* : R :: C : O. Also OB + BC = D + R will be as the opposite angle CAO or OAG, the sines of both being the same. Then as *m* : *n* :: *d* + *r* :

$\frac{Dn + Rn}{m}$, which will be as the angle CAf; this, taken from the angle ACO = *d*, leaves the angle AfO = $\frac{Dm - Rn - Dn}{m}$. Lastly, as the angle *f* : O :: AO or OB : Af or Bf; that is, as $\frac{Dm - Rn - Dn}{m}$: R :: D : $\frac{RDm}{Dm - Rn - Dn}$ = Bf, the distance of the point *f*

in the axis, after the first refraction. But since there is a second refraction of the ray AO to some other point in the axis, as F, in *fig. 7*. In this case, the refraction being out of a dense into a rare medium, the sine of incidence will be to that of refraction the *reverse* of what it was before, *viz.* as *n* to *m*; that is, the sine of IaF is to the sine of IaF as *n* to *m*, which, in the case of single refraction, was as *m* to *n*. Here let Ka be called *r*, and Ef = *d*; then there will be *d* : *r* :: K : *f*, and Ef + EK = *d* + *r*, which will be as the angle faK, or its complement IaF;

therefore *n* : *m* :: *d* + *r* : $\frac{dm + rm}{n}$, which will express the angle IaF. Then IaF - aKF = $\frac{dm + rm}{n} - d = \frac{dm - rm - dn}{n}$ = aKF. Now, as F : K :: Ka or

KB : aF or EF; that is, as $\frac{dm + rm - dn}{n}$: *d* :: *r* : $\frac{ndr}{dm + rm - dn}$ = EF. But Bf - BE = $\frac{DRm}{Dm - Rn - Dn} - t = d = Ef$; therefore, putting *m* - *n* = *b*, we shall have $d = \frac{DRm}{Db - Rn} - t = \frac{DRm - Dbt + rnt}{Db - Rn}$.

Also $dnr = \frac{DRmnr - Dbtnr + rntnr}{Db - Rn}$.

Again, $dm + rm - dn = Db + rm$; if, therefore,

we multiply the equation by *b*, and add thereto *rm*, we shall have $dm + rm - dn$

$$= \frac{DRmb - Dbtb + Rntb + Dbrm - Rnmr}{Db - Rn}$$

Then $\frac{dnr}{dm + rm - dn}$

$$= \frac{DRmnr - Dbtnr + Rntnr}{DRmb - Dbtb + Rntb + Dbrm - Rnmr} = EF.$$

This last equation may be abridged, by substituting *p* for $\frac{n}{b}$, that is, for $\frac{n}{m-n}$, then we shall have

$$\frac{pDRmr - pDbtr + Rntrp}{DRm - Dbt + Rnt + Drn - pRmr} = EF.$$

Lastly, if we take *n* = *pb* in *pDbtr*; and *m* - *n* = *b* in *Dbt*; this equation will be finally reduced to this fundamental equation, *viz.*

$$\frac{pDRrm - Dtrn + Rtrpn}{DRm - Dtm + Dtn + Rtn + Drm - pRrm} = EF = f.$$

The ratio of *m* to *n* being taken in glass as 3 : 2, we shall have $\frac{n}{m-n} = \frac{2}{3-2} = 2 = p$ for a glass lens, and the equation will then stand thus; *viz.*

$$\frac{6DRr - 2Dtr + 4tRr}{3DR - 3Dr - Dt + 2Rt - 6Rr} = EF = f;$$

and when *t*, the thickness, is disregarded, we have from this fundamental theorem all the various theorems contained in Table II. for finding the geometrical focus under all the various circumstances that are likely to occur in the position of a single lens, where the refractive power is not adverted to.

To illustrate the respective uses of the theorems contained in the two preceding tables, we must suppose the ratio between the sines of the angle of incidence and of refraction known by some of the usual modes of determining it experimentally; and then, when the ratio of *m* : *n* is so determined, there will be $\frac{m-n}{n} = a$, the symbol intro-

duced in the theorems of the first table; when *d* is equal to the distance of the radiant, *r* the radius, and *f* the proper focus determined by real refraction through the glass used,

the theorem for finding the value of *a* is $\frac{dr - rf}{2df} = a$.

For instance, Martin ground a piece of white flint-glass with a tool of 21.5 inches radius, into a double convex lens, and when a lamp was placed at the distance of 417.25 inches, the refracted focus was measured accurately, and found to be only 18.75 inches; whence, according to the theorem,

$$\text{we have } \frac{417.25 \times 21.5 + 21.5 \times 18.75}{2 \times 417.25 \times 18.75} = 0.599 = a = \frac{m-n}{n};$$

and if we put *n* = 1, then *m* will be 1.599, for $\frac{1.599 - 1}{1} = 0.599$. When the sun is the radiant, then

d becomes infinite, and the theorem becomes, as in the first table, $\frac{r}{2a}$, which gives, in this case, $\frac{21.5}{1.198} = 17.94$ for the

refracted

TELESCOPE.

refracted solar focus; whereas, by Table II., the geometrical focus is $\frac{dr}{d} = r = 21.5$. If the refractive power

of the glass, and consequently the value of a , had been given, and it had been required to determine the radius of the tool that will grind the given glass into such equal radii as will give the refracted solar focus exactly 17.82 inches, then

the theorem $\frac{r}{2a} = f$ becomes, by transposition, $2af = r$,

and $1.298 \times 17.94 = 21.5$, as before. In a specimen of crown-glass ground to the same radius, where d was 414.75

inches, $\frac{dr + rf}{2df}$ gave $a = 0.5318$, and consequently $m : n$

as 1.5318 : 1, with which lens the true solar focus was

$\frac{21.5}{1.0636} = 20.214$; and if the lens had been a single convex,

the true solar focus would have been $\frac{r}{.5318} = \frac{21.5}{.5318} = 40.428$,

or double the length of the former, while the geometrical focus for parallel rays, by Table II., would have been

$\frac{2dr}{d} = 2r = 43.0$; so that for many practical purposes,

where $m - n$ is known in the particular glass used, the advantage of the theorems in Table I., over those in Table II., must be evident

Again, let us suppose that the ratio of $m : n$ is ascertained by a prism of any specimen of glass, or by Dr. Wollaston's or Dr. Brewster's instruments for this purpose, and that it is known to be 1.599 : 1; then we know that $.599 = a$, as before; and let it be required to find the refracted focus with diverging rays, when the radiant is as before at the distance of 417.25 inches, and the radius of curvature of each surface 21.5: in this case the theorem is

$\frac{dr}{2ad - r} = f$, or, in numbers, $\frac{417.25 \times 21.5}{2 \times 0.599 \times 417.25 - 21.5}$

$= 18.75$, as before; and in this way the terms given may be varied at pleasure, and the theorem made applicable to the case in question. If the rays had been converging in

the last calculation, the theorem would have been $\frac{-dr}{-2ad - r}$

$= f$; or, changing all the signs, (which are here negative, because the distance is more than infinite, that is, the rays

more than parallel,) the same may be taken $\frac{dr}{2ad + r} = f$,

or $\frac{417.25 \times 21.5}{2 \times 0.599 \times 417.25 + 21.5} = 17.204$, which is less

than the solar focus by 0.74 of an inch. In this case the rays must have passed through some other glass, in order that they may proceed in a state of convergence before they enter the lens in question, and the focus of that other glass is here considered as the *radiant* point from which the rays proceed in a state of convergence; and this consideration leads us naturally to inquire into the nature of a focus when two glasses are employed jointly to produce it, under the different circumstances of figure and distance.

Suppose the parallel rays A N and B M, in *fig. 8*, to fall on a plano-convex lens M N, with the curved face turned to the radiant, and to be refracted to its focus at F; then if another plano-convex lens be placed in the line of its axis, at any distance less than C F, so as to intercept the converging rays, they will be refracted still more, and will now converge into the

shorter focus f , which is therefore called the *compound focus* of both the lenses. The angle subtended at f , where the eye is supposed to be placed, and which is called the optic angle, is now larger than that formed at F by the first lens, and is equal to what would be formed by the imaginary double convex lens E E, the focal distance of which would be Qf. Now let C F be put = F for the focal distance of the lens N M; O P = y for the focal distance of lens G H; and Qf = x for the focal distance of the imaginary double convex lens E E: also let O f, the compound focal distance, be = f; and C O, the distance between the lenses N M and G H, be = D. As the rays, which tend to the point F, after leaving the lens N M, fall on the lens G H *converging*, let us call O F = d, and then, by common optics, we shall

have $d = \frac{yf}{y - f} = F - D$; from which equation we get

$F + y - D : F - D :: y : f$; and from this analogy the compound focal distance O f is easily obtained. In like manner, the parallel rays L G and S H are refracted by the lens G H, now supposed to be the first lens, to the lens N M, as they proceed towards the point i; but are refracted to the nearer point ϕ , which is the compound focus on the

other side; and now we have $C\phi = \frac{F\phi}{F - \phi} = y - D$;

whence $F + y - D : y - D :: F : \phi = C\phi$, which is therefore known again, because of the similar triangles F N C, F G O, and $f E Q, f G O$; and because $E Q = N C$, we have $C F : O F :: N C (= E Q) : G O :: Q f : O f$; that

is, $F : F - D :: x : f$; and, therefore, $\frac{Ff}{F - D} = x$. But

we had above $\frac{F - D \times y}{F + y - D} = f$; which being substituted

for f , will give $\frac{Fy}{F + y - D} = x$; from which theorem our

problem for finding the compound focus of two lenses, or rather the focus of one lens, that shall have the same focal distance and visual angle as two given ones placed at a given distance shall have together, may be thus found: *viz.*

"divide the *product* of the two focal lengths of the given lenses by their *sum*, lessened by their *distance*, and the quotient will be the focal length of the single lens, as required." By way of exemplification, let the focus of N M be put = 6 inches, and that of G H = 4; and then, supposing the curved surfaces turned to the radiant, which is called the best position, as will be seen hereafter, and the distance = 2, we shall have, by the theorem for

this purpose, $\frac{6 \times 4}{6 + 4 - 2} = \frac{24}{8} = 3$ for the focus in ques-

tion; but if the distance had been = 3, then the result would have been $\frac{6 \times 4}{6 + 4 - 3} = \frac{24}{7}$, or 3.42 nearly. But if

the distance had been made 4, equal to the focal distance of the lens G H, the compound focus would have been 4 also; and if 6, equal to the focal distance of the lens N M, the compound focus would still have been 6, without any gain of magnifying power in either case, over what would have accrued from the respective single lens; also if the lenses are brought into contact, that is, if D = 0, then we shall have the compound focus the shortest possible, *viz.*

$\frac{6 \times 4}{6 + 4 - 0} = \frac{24}{10} = 2.4$. But *distinãtes* is an object

of as much importance as magnifying power; and it will be seen hereafter, that there is a certain distance between the lenses that promotes this quality the most possible, whatever be the radii of the two lenses. This condition is fulfilled when x is $= \frac{1}{2} F$, that is, when the focus of the imaginary lens EE is just one half of that of the outer lens NM ; in which case the compound focus f will be in the middle of the line OF , and the lens GH placed at half the focal distance of the imaginary lens. But it is not necessary that the object, or image of an object uv , should be situated in the exterior compound focus ϕ : this focus may be supposed negative, that is, the image may be between the two lenses MN and GH , as BA in *fig. 11.* which will always be the case when D is greater than y ; or, in other words, when the distance between the two lenses exceeds the focal distance of the inner lens GH ; for let

$$F = 6, D = 4, \text{ and } y = 2, \text{ and we shall have } \frac{6 \times 2}{6 + 2 - 4} =$$

$$\frac{12}{4} = 3, \text{ as in the first instance. Neither is it necessary that}$$

both the lenses be convex or plano-convex, nor yet with the same face outwards; for suppose NM concave, when its focus will be *negative*, or virtually on the opposite side of it, and must be expressed by $-F$; in this case the theorem becomes

$$\frac{-Fy}{y - F - D} = x, \text{ for the focus of the imaginary lens } EE$$

that shall have its focus equal to the compound focus, which will always be *positive* while $F + D$ is greater than y , but when less, then *negative*; and when $y = F + D$, the rays proceed parallel, and the focus is said to be *infinite*. The

$$\text{compound focal distance in this case is } \frac{-Fx - Dx}{-F} = f,$$

and must be affirmative when x is so; but when $D = 0$, then $f = x$. As an example, let the concave NM have a negative focal distance $-F = 3$, and let $y = 2$, while $D = 1$; then the focal distance of the imaginary or equal lens will be

$$\frac{-6}{2 - 4}, \text{ or } \frac{-6}{-2} = 3 = x, \text{ and the compound focal distance}$$

$$\text{will be } \frac{-3 \times 3 - 1 \times 3}{-3}, \text{ or } \frac{-12}{-3} = 4 = f. \text{ Whence, in}$$

this case, f is equal to $2FO$, whereas when NM was convex, we had the reverse, $FO = 2fo$. When $-F = y$, and $D = 0$, i. e. when a concave lens and convex one are placed in contact, with their separate focal distances equal, then x becomes infinite, or, in other words, the rays emerge, and proceed in a parallel direction; but if the focal lengths are unequal, there will be a positive focus and magnifying power, when the convex has the shorter radius; for suppose $-F = 3$, $y = 2$, and $D = 0$, then by the theorem

$$\frac{F \times y}{F - y}, \text{ we shall have } \frac{-6}{-1} = 6 = x, \text{ and in this case } x =$$

$f = 6$ likewise. From these instances it will be seen, on examination, that the *compound focal distance* Of , of the combined lenses, is nothing more than the focal distance f , found

$$\text{by the common geometrical theorem of optics, } \frac{dr}{d-r} = f,$$

adapted to the constant lens GH , where $OF = r$, and $OP = f$, when the rays are *diverging*; or $Of = -f$

$$\left(= \frac{-dr}{-d-r} \right) \text{ when the rays fall diverging on the said lens.}$$

See Table II.

Our general theorem may be rendered more extensive in its application, by varying it according to the data; thus,

$$\text{if } F, x, \text{ and } D \text{ be given to find } y, \text{ it will be } \frac{Fx - xD}{F - x} = y;$$

$$\text{to find } F \text{ with the others given, it will be } \frac{xD - xy}{x - y} = F;$$

$$\text{and to find } D, \text{ there will be } F + y - \frac{Fy}{x} = D. \text{ From}$$

these analogies we may further observe, that we have also the ratio of the two compound focal distances to each other, Of and Cf , thus; as $f : \phi :: F - D \times y : y - D \times F$; and, therefore, when $f = \phi$, then $F = y$; or the said focal distances can never be equal, but when the lenses are equal. Lastly, we may observe, that since the parallel rays LG , SH , refracted through both the combined lenses, intersect the axis in the same point, ϕ , as it would do if it were refracted by the single lens EE , as is evident by continuing it to R ; therefore, since $GO = RQ$, it will follow that the diameter IK , of the principal pencil of rays KcI , diverging from the focus ϕ , will be the same as it would have been, if it had proceeded directly to the single lens EE ; and, consequently, this combination of lenses makes no alteration in that respect.

Having now explained how the focal point of any lens, or pair of lenses, differently circumstanced, may be ascertained by one or other of the dioptric theorems, derived from the refractive power of glafs agreeably to certain laws of nature, it will be proper to explain the different senses in which the word *focus* is applied by optical writers under different circumstances, that our readers may not be at a loss to know in what sense it is to be taken, whenever it occurs in our subsequent details. The *principal* or *solar* focus of a lens, is that which is produced by parallel rays coming from an infinite distance, which that of the sun may be considered, and when the epithet *refracted* is added, it has reference to the particular glafs by which the rays are refracted; but when *geometrical* is expressed or understood, then glafs in general is meant: the *virtual*, refracted, or geometrical focus, is that which, in a concave glafs, would be formed by the diverging rays continued to a point backwards through the glafs till they meet, and is imaginary rather than real, and generally called *negative*: the focus arising from converging rays passing through a convex lens is shorter, or nearer the lens, than the solar focus, and the radiant is supposed to be at a greater than an infinite distance, if such an expression is allowable; but as no such distance is in nature, converging rays can only be produced by their passage through a first lens before they fall on a second, which is often the case in the construction of optical instruments: but the focus from diverging rays is always more remote than the solar focus from the lens that produces it; and, in consequence of the reference it has to the situation of the radiant or illuminated object, is denominated the *proper* and sometimes the *relative* focus; for as the radiant approaches the lens, the proper focus recedes in the same line, and *vice versa*, as we have more fully explained under the article *LENSES*. Because the radiant and corresponding focus may change places at any time, the two points where they are placed, at opposite sides of the lens, are called the *conjugate foci*, from their being so closely allied, that one cannot move without the other. When the radiant is placed therefore in the *princi-*

TELESCOPE.

pal or solar focus of a lens, the rays will emerge and continue parallel, on account of the other conjugate focus being at an infinite distance; and for the same reason, when an object, viewed by a single lens, is placed in its principal focus, the rays will enter the eye in a parallel state, and will be converged to a point on the retina by the humours of the eye, and a number of these rays crossing will form a picture behind the eye of the object viewed: for, what is one of the most remarkable properties of refracted rays coming from a luminous object, they bring with them not only the figure, but the colours of the object viewed, and form a picture or image of it, in the place where the different pencils of rays cross one another; and, what is equally remarkable, this picture is not visible until all extraneous light is excluded. We will not pretend to explain this wonderful property of a lens, that directs the transmitted rays so as to form a picture of a distant object in its focus, but merely mention here, that, without it, no telescope, microscope, camera obscura, or magic lantern, could be constructed on dioptric principles.

After having shewn, by our foregoing theorems, how any focus, solar, proper, conjugate, or virtual, may be determined of a single lens, or of a combination of two lenses with the intermediate distance given, the same might be done for any number of lenses, by considering the compound focus of the first two lenses, as the focal distance of a single lens, to be combined with the third lens, and so on till all the lenses are included. Dr. Smith has given, in his Optics, chap. v. the application of Cotes's theorem "for determining the apparent distance, magnitude, situation, degree of distinctness and brightness, the greatest angle of vision and visible area of an object seen by rays successively reflected from any number of plane or spherical surfaces; or successively refracted through any number of lenses of any sort, or through any number of different media, the surfaces of which are plane or spherical, with an application to telescopes and microscopes;" which account our readers may consult with advantage: but as the illustrations and demonstrations demand more plates than can be given to this article, in addition to the eight we have had occasion to introduce, we have been obliged merely to refer to them in this place.

We propose, however, to substitute some practical theorems, derived from our tables, which we have been favoured with by Mr. Tulley, that will be found extremely useful to the working optician, who must be supposed, generally speaking, unable to transform the theorems which we have given in our tables, for the purpose of finding the focal distance of a lens, or of a combination of lenses already constructed; and which tabulated theorems are principally useful for determining the powers, and for explaining the construction of an instrument to which they are applicable.

Practical Theorems.

1. When r , the radius of one face of a lens, is given, and F , its principal geometrical focus, to find R , the radius of the other face, the theorem is $\frac{rF}{2r - F} = R$ for a double convex: thus, let $r = 9$, and $F = 10.3$ inches, and the calculation will be $\frac{9 \times 10.3}{9 \times 2 - 10.3} = \frac{92.7}{7.7} = 12$ nearly, the truth of which may be proved by our theorem for parallel rays with a double convex lens, in Table II. viz. $\frac{2rR}{R + r}$, or

$$\frac{9 \times 12 \times 2}{9 + 12} = \frac{216}{21} = 10.3, \text{ as before very nearly, for the}$$

required focus; and when the refractive power or ratio between the sines of incidence and of refraction is given, this geometrical may be converted into the refracted focus by the quantity $2a$, used as a divisor; or, on the contrary, the refracted focus may be turned into the geometrical focus by using $2a$ as a multiplier.

2. With a meniscus lens, where r , the convex side, is given, together with F , the theorem is $\frac{rF}{F - 2r}$ for finding R , the concave side.

3. But when the concave side of a meniscus is given with the focus, to find the convex, the theorem becomes $\frac{rF}{2r + F} = R$.

4. When the focus of a double convex lens, and the ratio between its two radii, are given, to find the actual radii r and

R respectively, first our theorem in Table II. $\frac{2rR}{R + r} = F$,

will give the focus, on a supposition that one side is unity, and the other any given quantity that forms the other term

of the ratio; suppose as $1 : 4$; thus $\frac{1 \times 4 \times 2}{1 + 4} = 1.6$, the

rational focus; then suppose the focus given = 12 , and there will be this analogy, as $1.6 : 1 :: 12 : 7.5 = r$; and

also as $1.6 : 4 :: 12 : 30 = R$, or otherwise $\frac{12}{1.6} = 7.5$, and

$7.5 \times 4 = 30$ will be the respective radii r and R , as before.

5. When the compound focus of two convex lenses, and the separate focus of one of them, are given, to find the separate focus of the other, that shall be suitable to form the combination; if we put f = the focus of the lens given, F = the combined focus, and x = the focus of the lens required,

the theorem for this useful purpose is $\frac{fF}{f - F} = x$; for

example, let $f = 36$, and $F = 15$, then $\frac{36 \times 15}{36 - 15} = 25.7$

nearly, for the focus of the lens required, which is a positive focus, because both lenses are double convex, and might be plano-convex, or one double convex and the other plano-convex, or even meniscus, as the ratio of the radii r and R may be disregarded when the focus only is the object of consideration. But whatever be the forms of the curves relatively, F , the compound focus of two lenses, or more, will, in practice, be the refracted focus; and, therefore, in this theorem, f and x will also be the refracted foci of the separate lenses, and, consequently, when the geometrical focus of f is given, it must be converted into the refracted focus by the divisor $2a$, before the calculation is entered upon; it being necessary that all the terms be of the same denomination.

6. If F , the compound focus, be longer than f , the focus of the given convex lens, as is the case in the construction of a double achromatic object-glass, then the lens required will be concave, of which the focus x is sought, and

the theorem becomes $\frac{fF}{F - f} = x$. Let us, in this example,

TELESCOPE.

reverse the numbers of f and F , as taken above, by making $f = 15$, and $F = 36$; and then, as before, there will be

$$\frac{15 \times 36}{36 - 15} = 25.7 = x, \text{ the negative focus of the concave}$$

lens required, which may also have any ratio of its curves, or be a plano-concave, provided its focus be that which has been here determined.

Likewise it must be recollected, that when a positive focus is required from an union of two lenses, one convex and the other concave, the focus of the convex must be shorter than that of the concave; or, in other words, the refractive power, depending on the thickness of the lens, when the same glass is used for both lenses, must predominate in the convex; for it is the difference of the opposite refractions that brings the rays finally to a focus: consequently, if the foci are alike, the rays, being refracted alike in opposite directions, will become parallel, or have what is called an infinite focus: and also, if the focus of the concave be made the shorter of the two, the rays, after opposite refractions, will absolutely diverge by the difference of these refractions, and have an imaginary focus, called a virtual or negative focus, at the other side of the compound lens.

7. If the lens given be concave, and a convex one be required to produce a given compound focus, which is another case in the formation of an achromatic object-glass, the

theorem will be $\frac{fF}{F+f} = x$, where f is the focus of the

concave, and might be put $-f$, to denote its being a negative focus, and x the focus of the convex lens. Let us put $f = 25.7$, and $F = 36$, as above, and then there will

$$\text{be } \frac{25.7 \times 36}{36 + 25.7} = \frac{925.2}{61.7} = 15, \text{ very nearly, for the focus } x$$

of the convex required; which, as we have said, must be the refracted focus, and also f of a like denomination, in order to make the refracted compound focus suitable for a tube of thirty-six inches.

8. If the compound focus should be required to be *negative*, or to have the refraction of the concave lens to predominate, when the convex lens is given with the compound

focus, the concave may be found by this theorem $\frac{fF}{F+f}$

$= x$, as in the last; but then x here is the focus of the concave lens, which therefore will be 15 when that of the convex is 25.7, and the negative focus, as before, 36.

9. But if the given lens be concave, and the compound focus be required negative, the focus of the convex sought

will be had by this theorem $\frac{fF}{F-f} = x$, as in the sixth

theorem; the focus x is here, however, that of the convex, which in the other was that of the concave; so that when $f = 15$, and $F = 36$, x will be again $= 25.7$, but negative.

In all these cases, the two lenses are supposed to be in contact with each other; but if D , the distance between them, which is a variable quantity, were given, similar theorems

might be formed from our general theorem $\frac{fF}{f+F-D}$

above explained, where, in any position of two convex glasses, f is the focus of one lens, F the focus of the other, and D the distance between them, with a positive compound focus; but if one of the two lenses be convex, and the other concave,

the general theorem becomes $\frac{fF}{f-F-D}$ or $\frac{fF}{F-f-D}$,

accordingly as F , put for the concave, or f , put for the convex, is the larger: the former theorem being the "*product* divided by the *sum* of the foci, lessened by the *distance*," and the latter the "*product* divided by the *difference* of the foci, lessened by the *distance*." Hence, by a transposition of one or other of the forms of this general theorem, the data and postulata may be varied as occasion may require. The first form is applicable in cases where sliding eye-pieces, or a sliding secondary object-glass, are used in a telescope, which plans have been recommended and adopted by Dr. Brewster, as we shall see hereafter.

In considering the theory of a telescope, (of either the refracting or reflecting sort,) our attention must be directed to two essential particulars, the *image* of an external object formed at the focus of the object-glass, or of the large speculum, as the case may be; and the *means* by which this image is rendered visible to the eye of an observer: and accordingly as the dimensions, shape, quality, arrangement, and number of the lenses and specula vary from each other, may the constructions be said to differ, though the effect to be produced be intended to be the same. That telescope, of whatever construction, must be considered the most perfect, which exhibits to the eye an image of distant objects the most distinctly, as to light, colour, shape, and proportion; and which, at the same time, amplifies this image sufficiently to afford a minute examination of it, in a field of view that is proportionably large to contain it. That quality, which apparently amplifies the object, or rather the image of the object, by enlarging the angle subtended at the pupil of the eye, therefore called the visual angle, is denominated the *power* of the telescope; and in all telescopes, whatever their other qualities may be, the *light* is *diminished* as the *power* *increases*, so that in every telescope there is a limit to its useful power, which depends on the quantity of light emitted or reflected by the object to be viewed; and it would answer no good purpose to increase the power so much, that a corresponding deficiency of light may render the object invisible. Hence different powers may be applied, with advantage, to objects differently illuminated; and hence different eye-pieces are usually appropriated to the same telescope, particularly when it is destined for celestial, as well as for terrestrial observations. But we proposed to explain first the theory of those telescopes which are usually called *refracting* or *dioptric*, and afterwards of *cata-dioptric*, or those that magnify by the aid of *reflection*.

Under our article LENS we have said (in section 5.) that "the images of objects, opposed in any manner to a convex lens, are exhibited invertedly in its focus," and that "they will be represented distinctly, and in their natural colours," on a paper held at the opposite side of the glass, at nearly the distance of its proper focus, especially if the room be darkened; and in section 7. we have said, that "the diameter of the image of an object delineated beyond a convex lens, is to the object itself, in the ratio of the distance of the images to that of the object;" so that the more distant an object is from the lens, the smaller is the image of that object; and also the shorter is the focus of the lens, until the distance is such, that the rays fall on its surface parallel, or nearly so. Likewise (in section 8.) we have shewn, that "if the eye be placed in the focus of a convex lens, an object viewed through it appears erect and enlarged in the ratio of the distance of the object from the eye, to that of the eye from the lens, if it be near; but infinitely, if remote:" and what is said of an object itself, when viewed through a convex

TELESCOPE.

convex glass, is equally true of the *image* of an object so viewed. It is easy, therefore, to conceive, how two lenses of different focal lengths may be so arranged as to make a telescope that will at the same time invert and amplify, as to sense, a distant object: for, first, a lens of a long focal distance will form a large image of the object opposed to it, which image, by the crossing of the rays at the focal point, will be inverted a little beyond the solar focus: and secondly, an eye applied to a lens of short focal distance, which is held so that its focal point may coincide with that of the larger lens, will receive parallel rays, and will shew the said image in an amplified or magnified state, and in the same inverted position in which it is exhibited; which image, by being enclosed in a darkening tube, appears with all its natural colours. The power of such a telescope, which is the simplest that can be made, is ascertained by finding how often the focal length of the small or eye-lens is contained in the focal length of the larger or object-lens; the quotient of such division will represent the *power*. But if the eye-lens be made concave, and placed within the focal point of the object-lens, as much as is equal to the virtual focus of the concave lens, then the converging rays will become parallel, and afterwards, on entering the eye, which may be considered as a lens of short focus, will converge, and form a direct image on the retina; and though the total length of the telescope will be shortened by this latter arrangement, by twice the focal length of the eye-lens; yet if the virtual focus of the concave eye-glass be the same as the focal distance of the convex lens, the power will be the same, and may be ascertained by the same process. With a convex eye-glass, the instrument arising out of the first arrangement is the original *astronomical* telescope, and that arising out of the second is the *Galilean*. The field of view in the former construction is directly as the effective breadth of the eye-glasses, and inversely as the interval between the lenses; but in the latter, the field is directly as the diameter of the pupil of the eye, and inversely as its distance from the lens.

In both these constructions, the smallest power, or, which is the same thing, the shortest focus of the object-glass is with parallel rays; and as the distance of the object, or radiant point, decreases according to the principles of optics laid down under *LENS*, the focal distance of the object-glass increases: and thus the power increases as the rays become more and more diverging, from a gradual decrease of distance; so that, in fact, the same telescope magnifies a near object considerably more than it does a distant one; for while the focus of the object-glass increases after a certain law, inversely as the distance decreases, the focus of the eye-glass remains unaltered; and, consequently, the power varies inversely as the distance, or directly as the variable focus of the object-glass.

To remedy the inconvenience of inversion of the object in the astronomical telescope, and also of the contracted field of view of the Galilean, two more glasses were added to the eye-tube, as we before stated, to render the image of the object *erect*, or rather to form a second image in a contrary position. The primary intention of these two additional eye-glasses was not to alter the power, but merely to give an erect position to the apparent object; the original lens therefore remained as before, and was called the *field-glass*, as being nearest to the field of view of the old arrangement of two glasses, while the next glass was called the second eye-glass, and was placed at double its focal distance from the field-glass, so that the rays might be parallel, and that it might form another image in its focus: this being the image of an image, was denominated the secondary image, and became erect by a second crossing of the rays, and was then

viewed through the outermost or first eye-glass, in the same manner as the first or inverted image was viewed through the original eye-glass. This telescope was denominated the *terrestrial* telescope; and while the foci of all the three eye-glasses were similar, its power and field of view remained the same as in the astronomical telescope.

The theory of these three constructions will be more clearly understood by a reference to *Plate XXV.* of *Astronomical Instruments*, in which *fig. 1.* shews the arrangement of the glasses in the astronomical telescope; *fig. 2.* that of the glasses in the Galilean, and also in the common opera-glass, except that in it the object-glass is usually achromatic; and *fig. 3.* exhibits the system of glasses that compose the original terrestrial telescope, or perspective glass, before the subsequent improvements took place. In all these figures the same letters denote the same parts, as far as they extend; and the magnifying power of each may thus be demonstrated to be as we have before stated it. Let *AB* represent the object-glass, and *CD* the eye-glass of *fig. 1.*; and let *HFI* and *GFM* be considered as two pencils of light, proceeding in straight lines from the opposite ends of a distant arrow, and crossing each other at the centre *F* of the said object-glass; also let the dotted line be a pencil coming from the middle of the arrow, and falling perpendicularly on the same central point, so as to pass along the axis of the glasses *FLE*. Under these circumstances, the angle *GFH = IEM*, the opposite angle, is that under which the arrow appears to the natural eye at *F*; but the angle *IEM = CKD*, is that under which the image *IM* of the distant arrow is viewed, when magnified by the eye-glass *CD*. But the angle *IEM* is to the angle *IFM*, as *LF* to *LE*, or as the focal distance of the object-glass to the focal distance of the eye-glass; therefore

$\frac{LF}{LE} =$ the power, as before stated; and as the lenses *CD*,

NO, and *TU*, in *fig. 3.* have equal foci, the secondary direct image *PQ* is equal to the primary inverted one *IM*, and appears under the same angle.

Now if all the rays of light had been, as they were supposed to be before sir Isaac Newton's experiments, homogeneous; and if a double convex lens, of equal curvature on both sides, had been found to refract all these homogeneous rays into one focal point, without any aberration, either lateral or longitudinal; then the telescopes, we have just noticed, would have been sufficiently perfect for all the purposes of exhibiting a well-defined picture of the object viewed in a magnified state; and the power might have been increased to almost any extent, by varying the ratio between *FL* and *EL*; that is, by increasing the focal distance of the object-glass, or by lessening the focal distance of the eye-glass, or by both; but it was soon found that the rays which enter a lens at or near the edges, are refracted to a point nearer to its surface than the rays that are transmitted near the centre; and also that the rays of different colours are differently refracted, even from the same point of the lens, so as to meet in the line of the axis at different distances from the nearest surface of the lens. The former of these deviations, being occasioned by the spherical figure of the lens, is called the *spherical aberration*; and the latter, arising out of the nature of solar light itself, is called the *prismatic, chromatic, or Newtonian* aberration. The indistinctness in the formation of the image, occasioned by these aberrations of the rays of light, became an object of sir Isaac Newton's attention, and he soon discovered that, whatever mechanical means might effect in the shape of the curve that might rectify the spherical aberration, the prismatic aberration would

remain so long as one substance only remained to be the medium of refraction. The ingenious Huygens, however, supposing that the diminution of the spherical aberration would contribute greatly to the improvement of the telescope, instituted some experiments and calculations, which greatly promoted the science of Dioptries. He found, that the lengthening of the radius of convexity of an object-glass shortened the versed sine of the curvature, or lessened the thickness of the glass, on which, with equal apertures, the spherical aberration seemed to depend; and also that, in a simple eye-glass, the aberration from the figure was greatest in a double convex lens, when the curves of the two faces were from the same radius; and also that it increased as the radius shortened. The ratio 1 : 1 being found to have the greatest aberration, and 1 : 2 to have less, an investigation was instituted, from which it was at length proved, that the aberration in a double convex lens is the smallest possible, when the radii of convexity are to each other as 1 : 6; the face 1 being turned to the radiant or object to be viewed. From these experiments originated the famous Huygenian telescope of 123 feet focal distance, and a table of apertures corresponding to the respective focal lengths of the object and eye glasses, that would exhibit an image equally well defined: which calculations were the basis of all the long or aerial telescopes that were in repute for a whole century; but which are now superseded by the short achromatic refractors.

The same ingenious author of *dioptrics* discovered, that the aberration arising from the curved figure of a lens might be still further diminished, by substituting two lenses in the eye-piece of a telescope instead of one; which discovery was the foundation of all the improved eye-pieces that have been since adopted, under different arrangements of intermediate distance, and with different degrees of curvature. But before we can explain how the indistinctness arising from both the spherical and prismatic aberrations of mixed rays, may be in a great measure counteracted, (on which important consideration, the excellence of modern improved telescopes depends,) it is necessary to examine this subject further, and to shew how the circle of aberration of mixed rays arising from their unequal refrangibility, and also the lateral and longitudinal aberrations arising from the spherical figure of refracting and reflecting surfaces, may be mathematically determined. In doing this, we shall avail ourselves of Dr. Smith's propositions, which are at the same time perspicuous and conclusive.

PROP. I.

Aberrations.—"Let the common sine of incidence be to the sine of refraction of the *least* refrangible rays, as I to R, and to the sine of refraction of the *most* refrangible rays, as I to S; and the diameter of the least circular space, into which heterogeneous parallel rays can be collected by a spherical surface, or by a plano-convex lens, will be to the diameter of its aperture in the constant ratio of $S - R$ to $S + R - 2 I$."

For let an heterogeneous ray PA (*Plate XXVI. fig. 1.*) fall upon a spherical surface ACB, and let it be separated by refraction into the rays AF, Af, cutting the axis EC, drawn parallel to PA, in F and f. Take the arc CB equal to CA, and let another heterogeneous ray PB, coming parallel to PA, be refracted into the lines BF, Bf, cutting the two former rays in R and S. Join RS, and produce it till it meets the incident rays produced in I and K, and the perpendiculars EA, EB, to the refracting surface at the points A, B, in H and L. And when AB, the breadth of the aperture or of the pencil, is but moderate, and consequently the refractions at AB but small, the angles of incidence and

refraction HAI, HAR, HAS, or the arcs that measure them, or their perpendicular subtenses HI, HR, HS, will be to each other very nearly in the same given ratios as those of the sines I, R, S, of those angles. And disjointly, the differences of those subtenses will be proportionable to the differences of those sines; that is, the line RS : RI :: $S - R$: $R - I$, and doubling the consequents, RS : 2 RI or IK - RS :: $S - R$: $2 R - 2 I$; and conjointly, RS : IK, or AB :: $S - R$: $S + R - 2 I$. From this given ratio of RS to AB, in which they increase or decrease together, it appears that all the intermediate rays which fall upon AB, will pass through RS. And when parallel rays fall perpendicularly upon the plane side of a plano-convex lens, they are refracted only at their emergence from its convex surface; and so the aberrations are the same in both cases. Q. E. D.

Corol. 1.—Hence the diameter RS, of the circle of prismatic aberrations that contains all the incident rays, is a 55th part of the diameter AB of the aperture of a plano-convex glass, whatever be its focal distance. For supposing with Newton the prismatic spectrum divided into seven colours, and AR and AS to be the outermost red and violet rays, their sines of incidence and refractions I, R, S, are to each other as 50, 77, 78. Whence $S - R$ is to $S + R - 2 I$, as 1 to 55.

Corol. 2.—The diameter of the least circle that can receive the rays of any single colour, or of several contiguous colours, is also determinable from the proportions of their sines. Thus all the orange and yellow is contained in a circle, whose breadth is the 260th part of the breadth of the aperture of the plano-convex glass; the sines of the outermost orange AR, and yellow AS, being to the common sine of incidence, as $77\frac{1}{2}$ and $77\frac{1}{2}$ to 50.

Corol. 3.—In different surfaces, or plano-convex glasses, the angles of prismatic aberration RAS are as the breadths of the apertures A, B, directly, and as the focal distances C, F, inversely; because any angle, as RAS, is as its subtense RS directly, and as its radius AR or CF inversely.

Lemma.—The versed sines AB, AC, of very small arcs BD, CD, (*figs. 2. and 3.*) of unequal circles BDG, CDH, that have the same right sine AD, are reciprocally proportionable to their diameters BG, CH, very nearly; that is, $AB : AC :: CH : BG$.

For since the rectangles under BAG and CAH are each equal to the square of AD, and consequently to each other, their sides are reciprocally proportionable; that is, AB is to AC as AH to AG, or as CH to BG very nearly, when the versed sines are incomparably less than the diameters themselves. Q. E. D.

PROP. II.

"When homogeneal parallel rays NA, EC, (*fig. 4.*) fall upon a spherical surface AC, whose centre is E, the longitudinal aberration FT, of any refracted ray AT from F, the focus of the pencil, is to the versed sine of the arc AC, intercepted between the point of incidence and the axis ECF, in the given ratio of the square of the sine of refraction, to the rectangle under the sine of incidence, and the difference of the sines very nearly; and the aberration is the same when the rays fall perpendicularly upon the plane side of a plano-convex lens."

For when the refraction is made in the passage of a ray NA from a denser to a rarer medium, then the intersection T, of the refracted ray AT, with the axis ECF, lies between the refracting surface and its focus F. With the centre T and semi-diameter TA, having described the arc AD, cutting the axis in D, draw the sine AP of the arcs

AC,

TELESCOPE.

A C, A D, and also E N and E M, the sines of incidence and refraction, for which put n and m ; then because the triangles E T M, A T P, are similar, it will be as E T : T A or T D :: (E M : A P or E N ::) E F : F C; and disjointly, T F : E F :: (F C - T D or) T F - C D : F C; and alternately, T F : T F - C D :: E F : F C; and disjointly, T F : C D :: (E F : E C ::) $m : m - n$. Again, since (P D : P C :: C E : D T or F C and conjointly) C D : C P :: (E F : F C ::) $m : n$; by compounding this and the foregoing proportion, it will be as T F : C P :: $m m : m - n, n$. Q. E. D.

Corol. 1.—The segment A C B P A may be considered as a plano-convex lens; and when rays fall parallel upon its plane side, the longitudinal aberration of the extreme ray falling upon A is equal to $\frac{2}{3}$ of its thickness P C, as appears by putting 3 and 2 for m and n respectively.

Corol. 2.—Also this aberration $F T = \frac{m m}{m - n, n} \times \frac{A P^2}{2 E C}$
 $= \frac{m m}{m - n, n} \times \frac{A P^2}{2 C F}$. For P C = $\frac{A P^2}{2 E C}$ very nearly, and
 $E C = \frac{m - n}{n} \times C F$.

Corol. 3.—Let the refracted ray A T G produced, cut the line F G, perpendicular to the axis, in G, and the lateral aberration $F G = \frac{m m}{n n} \times \frac{A P^3}{2 E C^2} = \frac{m m}{m - n, n} \times \frac{A P^3}{2 C F^2}$. For
 $F G : T F :: A P : T P$, or C F or $\frac{n}{m - n} \times C E$.

Corol. 4.—When the semi-diameter of the convexity or the focal distance is given, the longitudinal aberrations arising from the figure are as the squares, and the lateral aberrations as the cubes, of the linear apertures of a plano-convex lens.

PROP. III.

“When parallel rays Q A, E C (*fig. 5.*) are reflected from a spherical concave A C B, whose centre is E, and whose aperture, A C B, is but small, the longitudinal aberration T F, of the extreme ray A T, from the geometrical focus F, is equal to half the versed sine C P of the semi-aperture A C very nearly.”

In *fig. 4.* imagine E M, the sine of refraction, to be diminished to nothing, and then to become negative and equal to E N, the sine of incidence, and the refraction of the ray to be changed to reflection, as in *fig. 5.*; and by the former proposition it will be, as T F : C P :: $m m : - m - n, n :: n n : - 2 n n :: 1 : - 2$.

But the particular proof is this: By the last lemma, the versed sine C P nearly equals half the versed sine P D of the arc A D, whose centre is T, and semi-diameter T A or T E, or half the semi-diameter of the arc A C very nearly. But $2 T F = 2 T E - 2 E F = E D - E C = C D$ exactly, or C P nearly. Therefore T F = $\frac{1}{2}$ C P nearly.

Corol. 1.—We had $2 T F = C D$ exactly, which is the excess of the secant E D of the arc A C above its radius E A. For joining A D, the angle D A E in the semi-circle D A E is a right one.

Corol. 2.—The longitudinal aberration T F = $\frac{A P^2}{4 C E}$.
 For C P = $\frac{A P^2}{2 C E}$ nearly.

Corol. 3.—The lateral aberration $F G = \frac{A P^3}{2 C E^2}$. For
 $F G : F T :: A P : P T$, or $\frac{1}{2} C E$ nearly.

Corol. 4.—When the diameter of the concave or its focal distance is given, the longitudinal aberrations are as the squares, and the lateral ones as the cubes of the diameters of the apertures.

PROP. IV.

“When parallel rays of any one sort are refracted by a plano-convex object-glass, or when rays of all sorts are reflected by a spherical concave, the diameter of each circle of aberration caused by the sphericity of the figures, is equal to half the lateral aberration of the extreme ray in each, and therefore is given by the former propositions.”

Let a Y τ be any refracted or reflected ray, cutting the axis E C T in τ (*figs. 6 and 7.*), and the extreme ray A T G, that comes from the contrary side of the axis, in Y. Draw Y X perpendicular to the axis; and supposing the line A T G immovable, as the point of incidence a moves from the vertex C, the perpendicular X Y will first increase, because the angle C τa continually increases, and afterwards will decrease, because the line T τ continually decreases; and when X Y is the greatest, it is evident that all the rays, incident upon the same side of the axis as itself, will pass through it. To find its greatest quantity, let the incident ray $q a$ cut the chord A P B in β , and supposing the variable aperture P $\beta = v$, the variable T X = x , and the given lines P A = a , P T = f , T F = b ; by Cor. 4. Props. II. and III. the aberration F τ is to the aberration F T (b) as πa^2 or P β^2 ($v v$) to P A² ($a a$).

Wherefore F $\tau = \frac{v v}{a a} b$, and thence T F - F $\tau = T \tau = \frac{b}{a a} \times \overline{a a - v v}$. Again, P T (f) : P A (a) :: T X

(x) : X Y = $\frac{a x}{f}$; also πa (v) : $\pi \tau$ or P T (f) :: X Y

($\frac{a x}{f}$) : X $\tau = \frac{a x}{v}$. Hence again, T τ , or X $\tau + X T = \frac{a x}{v} + x = \frac{b}{a a} \times \overline{a a - v v}$ found before; or $\frac{x}{v} \times \overline{a + v} = \frac{b}{a a} \times \overline{a + v} \times \overline{a - v}$. Whence $x = \frac{b}{a a} v \times \overline{a - v}$,

and therefore x or T X is the greatest possible when the rectangle $v \times \overline{a - v}$, or P $\beta \times \beta B$ is greatest, that is, when its sides P β , βB , are equal, or when $v = \frac{1}{2} a$. Substitute this value for v in the last equation, and it gives the greatest value of $x = \frac{1}{4} b$, or the greatest T X = $\frac{1}{4} T F$; and therefore the greatest X Y = $\frac{1}{4} F G$, because T X : X Y :: T F : F G; and this X Y, turned about the axis P X, describes the circle of aberrations through which all the rays falling upon A B will just pass. Q. E. D.

PROP. V.

“The circle of aberrations caused by the sphericity of the figure of the object-glass of a telescope, compared with the circle of aberrations caused by the unequal refrangibility of rays, is altogether inconsiderable.”

For the object-glass be plano-convex, and the plane side be turned towards the object, and the diameter of a sphere, whereof this glass is a segment, be called D, and the semi-diameter of the aperture of the glass be called S, and the sine

TELESCOPE.

line of incidence out of glass into air be to the sine of refraction as n to m ; the rays which come parallel to the axis of the glass shall, in the place where the image of the object is most distinctly made, be scattered all over a little circle,

whose diameter is $\frac{m m}{n n} \times \frac{S^2}{D D}$ very nearly, if they were all equally refrangible. As for instance, if the sine of incidence n be to the sine of refraction m as 20 to 31, and if D , the diameter of the sphere to which the convex side of the glass is ground, be 100 feet, or 1200 inches, and consequently the telescope about 100 feet long, and S , the semi-diameter of the aperture, be two inches; the diameter of this circle of aberrations, that is $\frac{m m}{n n} \times \frac{S^2}{D D}$, will be

$$\frac{31 \times 31 \times 8}{20 \times 20 \times 1200 \times 1200} \text{ or } \frac{31^2 \times 8}{20^2 \times 1200^2} \text{ parts of an inch.}$$

But the diameter of the little circle through which these rays are scattered by unequal refrangibility, will be about the 55th part of the breadth of the aperture of the object-glass, which is here four inches. And therefore the aberration arising from the spherical figure of the glass, is to the aberration arising from the different refrangibility, as $\frac{1}{55}$ to $\frac{1}{5449}$, that is as 1 to 5449; and therefore, being in comparison so very little, deserves not to be considered in the theory of telescopes. If we suppose the little circle of aberrations arising from unequal refrangibility, to be 250 times narrower than the circular aperture of the object-glass, it would contain all the orange and yellow, and would permit the other fainter and darker colours to pass by it, which perhaps may scarcely affect the sense; yet even in this case, the aberration caused by the spherical figure, would be to the aberration caused by the unequal refrangibility, in a 100-foot telescope, but as $\frac{1}{55}$ to $\frac{1}{5449}$, or only as 1 to 1200, which sufficiently proves the proposition. Q. E. D.

Corol. 1.—If the focal distances and apertures of a reflecting concave and a plano-convex glass be both the same, the diameter of the circle of aberrations, caused by their figures, will be above 30 times less in the reflector than in the refractor.

For these diameters are $\frac{A P^3}{16 C F^2}$ and $\frac{m m}{m - n^2} \times \frac{A P^3}{4 C F^2}$; which are as $\frac{1}{4}$ to $\frac{m m}{m - n^2}$ or $\frac{31 \times 31}{11 \times 11}$.

Hence, if the length of each telescope be 100 feet, the lateral aberrations in the reflector would be 30×5449 , or 163470 times less than the lateral aberrations caused by unequal refrangibility in the refractor.

Corol. 2.—The number of pencils, some of whose rays are mixed together in every point of a confused picture, is as the area of the circle of aberrations of the rays in any one pencil; and consequently the mixture of the rays of different pencils, caused by the sphericalness of the figure of an object-glass, if they were all alike refrangible, would be to their mixture caused by their unequal refrangibility, as 1 to 5449×5449 , or 29691601 in the present instance. For conceiving any point in the confused picture to be a centre of a circle of aberration, it is manifest that all other equal circles of aberration, whose centres fall upon the first-mentioned circle, will cover its centre, that is, some rays of as many pencils will be mixed in this centre as there are points in the circle itself; or, which is the same thing, the number of pencils mixed in this centre is as the area of the circle of aberrations."

Double achromatic Object-glasses.—From these five propositions, and the corollaries deduced from them, in all of which the ratio of the sines of the angles of incidence and of refraction out of air into glass is taken as 3 : 2, (which answers nearly to the French plate-glass,) our readers will see, that when any single lens is used as the object-glass of a refracting telescope, there will be not only fringes of colour, but indistinctness in the image formed at its focal point, arising respectively out of the two kinds of aberration, the prismatic and the spherical. But Dollond has shewn, that these aberrations are not the same in all sorts of glass: the former depends on the dispersive power of the glass used, and the latter on the ratio of the radii of curvature of the two surfaces of the lens. The dispersive power of a prism of any specimen of glass will be to that of another like prism of a different specimen, as the lengths of the prismatic spectra, formed by them, are respectively to each other: and if the foci of two lenses of different dispersive powers, one convex, of crown-glass for instance, and the other concave, of flint, be made directly as their dispersive powers, and be placed contiguous, so that the convex lens may receive the rays first, and be of the shorter focus, or thicker, its dispersive power will be so counteracted by the opposite dispersive power of the other thin lens of longer focus, that the extreme or prevailing colours of the primary spectrum, being reversed, will both disappear; and a secondary spectrum, composed of the remaining intermediate colours, will be very inconsiderable in a good achromatic object-glass thus composed. If the refracted focal distances of the two lenses remain unaltered, when duly proportioned, as 2 : 3, or nearly so, the proportion of the radii of the surfaces may be altered at pleasure, so as to produce their due proportions of spherical aberration. To effect the desirable purpose of banishing the spherical aberration as much as possible, the optician is obliged to calculate the aberrations belonging to convex lenses of different unequal radii, in order to make the contrary aberrations of the concave as equal thereto as may be; and for this purpose the general theorem of Huygens is peculiarly adapted, which we shall, therefore, introduce and exemplify here, before we proceed to the construction of an achromatic object-glass. According to this theorem, if we put r for the radius of the first surface of any lens, or that which first receives the incident rays; R for the second surface; and T for the thickness of the lens: then the aberration arising from the figure of any lens, concave or convex,

$$\text{will be} = \frac{27 r^3 + 6 r R + 7 R^2}{6 \times r + R^2} \times T \text{ universally. (See}$$

Martin's New Elements of Optics, part vi. chap. iii. and Dr. Smith's Optics, book 2. chap. xiii.) When the centres of the curves are on opposite sides of the lenses, the signs are as here put down; but if these centres are on the same side as in a meniscus, then the sign of r , or of R , must be negative, as the case may require. For instance, let us first put r and R equal, and each = 1; then, as unity is not altered by multiplication or division, we shall have the

$$\text{simplest case, viz. } \frac{27 + 6 + 7}{6 \times 2 + 2} = \frac{30}{14} = \frac{15}{7}, \text{ or } 1.66 \text{ of}$$

T , for the longitudinal aberration, and it will make no difference which face of the lens is turned to the radiant. Secondly, let us take $r = 1$, and $R = 2$, in which case

$$\text{we shall have } \frac{27 + 12 + 28}{6 \times 9} = \frac{67}{54} = \frac{13}{10}, \text{ or } \frac{1}{3} \text{ of } T, \text{ very nearly.}$$

But if we reverse the sides in position, by making $r = 2$, and

TELESCOPE.

and $R = 1$, then the result will be different, *viz.* $\frac{108 + 12 + 7}{6 \times 9} = \frac{127}{54}$, or nearly $\frac{1}{4}$ of T . The aberration

here is more than in the former position, in the ratio of $127 : 67$; and this is, therefore, called the *worst* position; that being always called the *best*, where the first surface has a shorter radius than the second. If we suppose lenses of unequal radii to have their focal distances, their breadth, and consequently their thickness the same, it will be found, by a similar process, that their aberrations will diminish, as R continues to exceed r , until r is to R as $1 : 6$; in which construction of a lens, placed in its best position, the aberration will be a *minimum*, *viz.* $\frac{1}{4}$ of T ; but in its reversed or worst position, the aberration will be $\frac{1}{4}$ of the same. A single convex lens, in its best position, has its aberration only $\frac{1}{6}$ of T ; but with the plane side turned to the radiant, in which r may be said to be infinite, the aberration will be $\frac{1}{2}$ of T . Also a double convex, when its radii r and R are to each other as $2 : 5$, has the same aberration as a single convex in its best position, and has less spherical aberration than any meniscus whatever; but there is no proportion of the radii of any one lens that will do away the spherical aberration altogether. If the refractive power of any glass be such, that the sines of incidence and of refraction are not exactly in the ratio $3 : 2$, the calculated longitudinal aberration will differ a little from the true one, so as to require a correction. And with respect to the lateral aberration, if m be the sine of incidence, and n the sine of refraction $= 1$, where two lenses have equal apertures and radii, then the errors arising from obliquity of incidence will respectively be as m^2 in one, to $'m^2$ in the other.

Likewise, we derive from the foregoing demonstrations of Dr. Smith the following general and important conclusions: first, that in lenses of equal apertures, the *longitudinal* aberrations, arising from figure, are *inversely* as the focal distances (see Cor. 2. of Prop. II. above quoted); and secondly, that under like circumstances, the *lateral* aberrations are *inversely* as the squares of the said focal

distances (see Cor. 3. of the same Prop.); and, on the contrary, that when the focal distances are the same, and the apertures differ, then the *longitudinal* aberrations are as the squares (see Cor. 4.), and the *lateral* as the *cubes* of those apertures. The utility of these proportions will more fully appear in the sequel.

We proceed now to the most important part of our article, *viz.* to shew what means have been not only devised, but practically applied, for remedying the defects arising out of these two different kinds of aberrations, and for rendering the apparent object, as viewed through a refracting telescope, at the same time distinct and colourless. Telescopes of what are called the *achromatic*, (from α , priv., and $\chi\rho\omega\mu\alpha$, colour,) or colourless kind, are composed, like other telescopes, of two parts requiring separate consideration; *viz.* the object-glass and the eye-tube: the former being that which produces an *image* free from colours and mistiness; and the latter that which either renders this image visible, or produces a secondary one to be viewed, without the reproduction of colours. But our present consideration is that of the object-glass.

Before the working optician can proceed to prepare his tools for making an achromatic object-glass, he must know the refractive and dispersive powers of his glass. Various methods have been proposed for determining these qualities with accuracy; but it will be sufficient for our purpose to explain those which have been found most practicable. As the ratio between the sine of incidence and the sine of refraction is constant in the same glass, though not the same ratio in different sorts of glass, the most certain method of determining this ratio in different specimens of glass is, to grind a piece of each of those specimens by the same tool, as Martin and Tulley have done, and then to compare their refracted solar foci with the radius of curvature; and those which have the shortest refracted foci, will have the greatest refractive power; and the contrary. We have already explained, in the first section of our article, how this operation was conducted by Tulley in particular; and we will now state the results of his experiments in the subjoined little table.

Results of practical Experiments on the refractive Powers of different Specimens of Glass, by C. Tulley.

Kinds of Glass.	R Radius of Tool.	F Focus of re- fracted Rays.	$\frac{R}{F} - 2a$ a Divisor.	Ratio of the Sines of I and R.	Specific Gravity.	Ratio of dispersive Powers.	Kinds of Glass used together.
Flint 1. -	33.7	28.13	1.198	1.599 : 1	3.466	1.757 : 1	used with crown.
Flint 2. -	33.7	29.38	1.147	1.5735 : 1	3.192	1.524 : 1	used with crown.
Ratchiffe crown	33.7	31.91	1.056	1.528 : 1	2.527	1 : 1.757 1 : 1.524	used with flint 1. used with flint 2.
Dutch -	33.7	32.12	1.049	1.524 : 1	2.519	not known.	
Plate 1. -	33.7	33.43	1.008	1.504 : 1	2.450	1 : 1.65 1 : 1.623	used with flint 1. used with flint 2.
Plate 2. -	33.7	33.56	1.004	1.502 : 1	2.428	1.195 1.167	used with flint 1. used with flint 2.

If we explain how the numbers in the horizontal column of flint 1. were obtained, the rest of the table will require no further explanation. The tool on which the six specimens of glass were ground at the same time, was of speculum metal, and did not vary its shape much during the operation

of grinding and partial polishing, which was all that the glasses required for viewing the sun, and for adjustment to the solar focus. The first flint-glass, after being thus formed to a curvature on both sides of 33.7 inches radius, equal to that of the tool, was put into a tube and made into a temporary

porary telescope, when the principal or solar focus, from actual refraction of the rays, was found to be 28.13 inches, which is therefore called the *refracted* solar focus, the geometrical focus derived from the radius of curvature being 33.7. This is the specimen of glass of the greatest density as well as of the greatest refractive and dispersive powers, its specific gravity having been repeatedly ascertained to be 3.466 with different hydrostatic balances of the most delicate construction. Now if the radiant had been at a near distance, instead of the sun being used, Martin has shewn

that the value of $a = \frac{m-n}{n}$ may be had from this theorem,

$$\text{viz. } \frac{dr + rf}{2df} = a \text{ (where } d, r, \text{ and } f, \text{ are as in our Table I.}$$

of Theorems), which is demonstrated in his Philosophia Britannica; and from this theorem he determined the focal distances and quantity a of his specimens of glass; but when the sun is used as the radiant, the distance becomes *infinite*; and then, neglecting rf as infinitely small, the left-hand term

becomes $\frac{dr}{2df}$, and the theorem, by ejecting d from the

numerator and denominator, is reduced into the form $\frac{r}{2a} = f$,

as in our Table I. for parallel rays with a double convex of equal radii. Tulley, therefore, very properly preferred taking the solar focus at once, instead of taking a measured distance for the place of the radiant, and of calculating from a long theorem, and from data that might not be perfectly correct; his results, therefore, must be considered as being more satisfactory than Martin's. The reduced theorem

$\frac{r}{2a} = f$, by transposition becomes $\frac{r}{f} = 2a$, and also $f \times$

$2a = r$; hence $2a$ may be either a divisor or multiplier, accordingly as r or f is given to find the other. Tulley has called this quantity a *divisor*, because, having the radius or geometrical focus of a glass always, from the known radius of his grinding tool, he can get the *refracted* focus by the proper divisor and a simple calculation at any time; which mode, as we shall see presently, is very useful in the calculation of the compound focus of an achromatic object-glass. Now to get the actual quantity of $2a$ in figures, there will

be $\frac{33.7}{28.13}$ taken from the third and fourth vertical columns,

which may be called $\frac{R}{F}$ or $\frac{r}{f} = 2a = 1.198$ for the said

divisor, one half of which is $.599 = a$. Put now m , as before, for the sine of incidence, and n for the sine of refraction, and we have seen above that $\frac{m-n}{n} = a$. Let

$n = 1$, and then $m = 1.599$; for $\frac{m-1}{1} = a \therefore m = 1 + a$

$= 1.599$, and $\frac{1.599-1}{1} = .599 = a$; therefore the sine

of incidence is to the sine of refraction in this first specimen, in the ratio of 1.599 : 1; and in like manner the horizontal columns for all the other specimens are filled up with very

little trouble, when $\frac{R}{F}$ is ascertained by simple division of the tabular or experimental numbers.—With respect to the

vertical column of dispersive powers, these powers are best ascertained by making six equal prisms of the same specimens of glass, and by measuring the coloured solar spectra of each separately, under exactly the same circumstances of distance, inclination, position, &c.; and as the angle of dispersion is measured by the coloured spectrum as its subtense, the angles of dispersion of the different specimens will vary with the respective lengths of their spectra; and if the refracting angle of one of the specimens, the first flint for instance, be diminished by grinding and fresh polishing, until its spectrum is of precisely the same length as that of any other, say the crown, then the ratio of their refracting angles will be inversely the ratio of their dispersive powers; and a pair of analogous lenses, one convex and the other concave, (such as those seen in *Plate XXVIII. figs. 5. and 6.*) will have their dispersive powers so counteracted, that a pencil of rays incident on the thick crown-glass will emerge from the thin flint *colourless*, and will proceed without colour, notwithstanding the greater refractive power of the convex lens, till, by being refracted, they finally cross the axis in which the focus is formed; and the focal point will be more or less distant with a pair of lenses so combined, accordingly as the difference of the two refracting powers is greater or smaller. To explain this analogy between a pair of prisms and a lens, either convex or concave, we will shew how a pencil of solar rays passing through a prism of glass is dispersed at the second surface, so as to form the solar spectrum composed of the prismatic colours: Let abc , in *fig. 9.* be a triangular piece of glass, called a prism, and d a pencil of solar light, entering the prism at e , in the line deB , parallel to the base ac : on entering the glass it will be refracted towards this base, and emerge at the point f , a little nearer to c than e is to a . At this point of emergence, f , the pencil will begin to *disperse* into rays of different colours, but whether into seven or any other number, is not our present object to enquire. Let AB be a screen, receiving the dispersed pencil in a darkened room, and fg will be the ray of mean refraction, fb will be the red ray, or ray of least refraction, and fi will be the violet ray, or ray of greatest refraction, hi being the length of the coloured spectrum. Let this prism be of crown-glass; then substitute another of flint-glass, exactly in the same situation, and the extreme rays, h and i , will now be dispersed to H and I , and the distance between those new points will be the length of the spectrum with flint-glass. Now the angle gfb with both prisms is called the angle of *deviation*, or of mean refraction; the angle ifb is called the angle of *dispersion* with the crown, and IfH the same with the flint prism; but these angles of dispersion are subtended by the lines hb and Ih respectively, which are the lengths of their respective spectra, which therefore are the *measures* of the angles of *dispersion* of the two different prisms. Martin found these exactly as 3 : 5, and therefore recommended the geometrical foci of the crown and flint glasses to be *always* in this proportion; but Tulley has found that this ratio will not be accurate with all specimens of flint-glass, and therefore takes a different ratio, for each specimen of glass that differs in this quality, from Martin's. In the same specimen of glass, the angle of *deviation* always bears the same proportion to the angle of *dispersion*, or *dissipation* as it is sometimes called; and it was the opinion of sir Isaac Newton that this is the case in *all specimens*; but it remained for the senior Dollond to discover, which is the basis of all achromatic constructions of an object-glass, that *the angles of deviation may be the same, when the angles of dispersion are not the same, and vice versa*; and we have a striking instance in crown and flint glass, in which, when the dispersive powers

TELESCOPE.

powers are made to balance each other in opposite directions, there yet remains a balance of refractive power in favour of the crown, arising from its greater thickness, which disposes colourless rays still to deviate or be refracted, but to a more distant focus than would have been if the crown had been used alone. This effect may be seen in *fig. 10*, where a pair of prisms, *a* and *b*, are inscribed in the double convex lens of crown-glass, and the pair *c* and *c* within the double concave of flint: the incident rays *de* and *de*, at each side of the axis *g o*, enter the convex at the points *e* and *e*, and are refracted towards the axis, till they meet with the inverted prisms *c* and *c* of flint, when they are refracted in a contrary direction, so as to prevent their meeting at the point *o* of the axis to which they tended, and emerge at the points *f* and *f* colourless, in consequence of the opposite dispersions which take place in the prisms; but after emergence they tend to a new and more distant point *O* in the axis, and there come to an achromatic focus.

To render this explanation still more intelligible with respect to the *opposition* of two counteracting dispersions, let there be two separate prisms, placed, as in *fig. 11*, at a distance from each other, and inverted with respect to each other; let *abc* be the prism of crown-glass, and *ABC* a similar one of flint-glass; and let two pencils of white light enter these lenses in opposite directions, one *d*, and the other *D*; then *g* and *G* will be the rays of mean refraction, *b* and *H* those of least, or red; and *i* and *I* those of most, or violet. Now as the refractive power of the flint prism *A B C* is greater than that of the crown *a b c*, the mean ray *G* in the first will be nearer its prism, than *g*, the mean ray of the second, to its prism; but the angle of dispersion subtended by *H I*, will be greater than that subtended by *b i*, while the prisms have the same refracting angles *C* and *a*. Now as the refraction and dispersion in the same prism are proportionate to the refracting angle, these may be both reduced to any assignable quantity by a reduction of the refracting angle; then let the side of the prism of flint *C A* be ground down till it becomes *C K*, thereby making the angle *B C A*, the original refracting angle, equal *B C K*, the new refracting angle; and let this second angle be to the first as the refractive power of the crown is to the refractive power of the flint; or, in other words, let the refracting angles *C* and *c* be inversely as the refractive powers of the two specimens of glass formed into prisms; *viz.* as that of *g f F*: *G F f*; and then the mean ray *G* will be extended to *c*, and *F c* will be parallel to *f C*; that is, the mean refraction of the two lenses will be alike, the angle *G F f* = $\angle g f F$, by being alternate. In this situation of the refracting angles of the opposite prisms, the rays would both enter and emerge parallel as to *refraction*; but as to *dispersion*, that of the flint would still predominate a little, or the angle *H F I* would in some measure exceed the angle *b f i*: but these are the angles we want to have equal; therefore, to make the refracting angles *C* and *c* of the two prisms proportional to the *dispersive* powers, or to the spectra *b i* and *H I* in *fig. 9*, let the side *B C* also of the flint prism be ground down a little to *l*, so that the refracting angle *l C k* of this flint, shall be to the refracting angle *a c b* of the crown in this ratio of the spectra; and then not only will the dispersive powers of the two prisms become equal, but, what is equally necessary, *G* will now fall beyond *c*; that is, the refractive power of the flint by this second diminution of its refracting angle, will become less than the refractive power of the crown, and the difference of these powers will refract the transmitted rays, as in *fig. 10*, finally to the distant point *O*, as has been explained, while at the same time the rays that arrive there will be without colours. If now we conceive that the re-

fracting angle of each of the flint prisms *c* and *c*, in *fig. 10*, inscribed within the concave lens *c c*, is so proportioned to the refracting angle of the prisms *a* and *b*, inscribed in the convex lens of crown *a b*, as the refracting angle *l C k* of the flint prism in *fig. 11*, is to the refracting angle *a c b* of the crown prism, then the double object-glasses in *fig. 10* will be achromatic; its lenses being analogous to the correcting prisms. Thus the theory of a double achromatic object-glass is within the comprehension of our ordinary readers; and as the triple object-glass has two thin convex lenses of crown, instead of one thick, to combine with the flint concave one, a farther explanation is unnecessary, particularly if the thick double convex be supposed to be divided longitudinally into two plano-convexes, and to be placed one on each side of the concave: for when these plano-convexes are formed into two curves, giving the same focal distance each as one of the plano-convexes, then the union of the three lenses will be that represented in *fig. 7*.

We may now proceed to exemplify this theory, arising out of Dollond's grand discovery; and to make the construction as familiar as possible, we will avoid all fluxional calculations, and explain such algebraical ones only, as are indispensable, in the first example at full length, as they occur, so that the abridgments in the subsequent examples may be clearly intelligible. Our aim differs from that of our predecessors in this respect. The illustrious mathematicians Euler, d'Alembert, Clairaut, Boscovich, Klugel, and Robison, have given formulæ for the calculation of achromatic object-glasses, that are above the comprehension of ordinary opticians; and Dr. Brewster has calculated tables, according to these formulæ, of the different curves that suit a *certain specimen* only of flint-glass, and that such as is not to be found, at least in England; *viz.* that which has its sines of the \angle of incidence and of the \angle of refraction as 1.604 : 1. Besides, the calculations tabulated are not in a practical form in Table II., the radius of the convex being shorter than that of its contiguous concave. On the contrary, we propose to take glass that falls in our way, and to calculate in a familiar manner the radii of curvature that shall suit specimens already within our reach. In short, our predecessors shew how achromatic object-glasses *may be made*, if *proper glass could be obtained*; and we will explain how achromatic object-glasses *are made*, and in the *best* manner, with glass of our own manufacture.

Example 1.—Let it be required to form a double object-glass of thirty inches focal length, from the second flint-glass and crown-glass given in Tulley's table of experimental results? In the crown-glass, the ratio of the sines of the angles of incidence and of refraction (*m* : *n*) is 1.528 : 1; and in the flint-glass it is 1.5735 : 1; while the ratio of their dispersive powers are .500 : .762, or 1 : 1.524. The first step is to determine the ratio of the geometrical focus of the first or crown-glass, to the compound focus of the proposed pair of glasses, in order that the radii of this lens may be known, before its proper companion, the flint lens, have its focus determined. It will be convenient to call the radius of the convex *r*, and as it is proposed to have it a double convex, the geometrical focus will also be *r*; but as the compound focus of both lenses is the *refracted* focus always, the geometrical focus *r* must be turned into the refracted focus also, in order to have both of the same denomination: but to do this we want the divisor, which may be taken from the table, or derived from

$$\frac{m - n}{n} \times 2; \text{ thus } \frac{1.528 - 1.000}{1.000} = .528 \times 2 = 1.056, \text{ the}$$

TELESCOPE.

divisor of the crown; and $\frac{1.5735 - 1.000}{1.000} = .5735 \times 2 = 1.147$, the divisor of the flint. In the next place we have $\frac{1.000}{1.056} = .94697$ for the refracted focus of the crown lens;

and because the foci of the crown and flint lenses must be in the same ratio as their dispersive powers, which we have stated to be 1 : 1.524, we shall have $\frac{1.524}{1.147} = 1.3827$ for the

refracted-focus of the concave or flint-glass. Now, having .94697 : 1.3827 as the ratio of the two separate refracted focal distances that shall banish all colours by their equal and opposite dispersive powers; we next find what will be the compound focus corresponding to these two when put in contact. Let F be the focus of the convex, and 'F that of the concave; and by our *practical* theorem 5. there

will be $\frac{F \times 'F}{'F - F} =$ the compound focus, which in plain numbers will stand thus; $\frac{.94697 \times 1.3827}{1.3827 - .94697} = 3.29$, the

proportional compound focus required. Now if the prismatic aberration were the only one necessary to be counteracted, we have already obtained numbers that would enable us to construct an *achromatic* or colourless compound object-glass; for

if we multiply F, 'F, and f alike by $\frac{30}{3.29}$, or 9.12, the

geometrical focus of the convex lens, we should have the absolute refracted focus of $F = .94697 \times 9.12 = 8.636$; that of 'F $= 1.3827 \times 9.12 = 12.61$; and the compound focus $= 3.29 \times 9.12 = 30$ very nearly; and it would be immaterial what the curves were, provided the refracted focal distances of F and 'F were as above stated: but as the tools for forming the curves respectively for the sides of these lenses, must have regard to the *radii* of curvature, it would be now necessary to use the *divisors* as *multipliers*, to convert the refracted into the geometrical foci, and then the business might be put in hand. On this supposition, of there being only one kind of aberration, the construction of a compound achromatic object-glass would be no difficult affair; for while the focal distances only are required to be to each other in a given ratio, the radii of curvature might be varied almost at pleasure, without affecting the focal distance. But there yet remains the spherical aberrations of the two separate lenses to oppose to each other in such proportion, that their tendency to produce *indistinctness* may be completely obviated. Before the time of sir Isaac Newton, this was the only kind of aberration that opticians thought they had to contend with; and though it is small in *quantity*, compared to the prismatic aberration, yet it is more difficult to conquer. It is, however, contrary to the opinion of that great philosopher and mathematician, in the power of the modern optician to cure this defect of spherical glasses, by means equally simple, when determined, as those by which the prismatic colours are made very nearly to vanish. As in the annihilation of the prismatic colours, the *ratio of the focal distances*, made directly as the ratio of the *dispersive powers*, is a cure for the first imperfection; so the *ratio of the radii*, $r : R$, of the two lenses, so calculated as to counteract each other's spherical aberrations, is the cure for the second imperfection; and this cure we have yet to apply,

without interfering with the remedy which we have just prescribed for the other. In order to mark the distinction that must be made in the symbols, as applied respectively to the convex and concave lenses, let it be understood, that the subjoined notation will be attended to in our investigation of the curves proper for our present purpose; *viz.*

Convex.	Concave.	
r	'r	means the radius of the first surface.
R	'R	means the radius of the second surface.
F	'F	means the focus from solar rays, or geometrical, if so expressed.
T	'T	the thickness of the lens.
A	'A	the spherical aberration.
m	'm	the sine of incidence.
n	'n	the sine of refraction.
φ		the compound focus.

It may be also necessary to premise, that whatever ratio of the radii r and R be fixed upon for the convex lens, the ratio 'r : 'R of the concave may always be found by proper investigation such, that its aberration will counteract that of r : R; but the reverse is not true; the aberration of 'r : 'R may be too great for the aberration of any ratio r : R to equal; therefore the ratio r : R is first assumed, as is most convenient for the optician's tools already formed; and 'r : 'R must be so calculated, that its aberration shall be in due proportion for correcting the aberration of the assumed convex lens. We now have to do with the *geometrical* foci of both lenses, when their *radii* become the

subject of investigation; and we have seen that $9.12 \left(\frac{30}{3.29} \right)$

is the geometrical focus of the convex lens, therefore $1.524 \times 9.12 = 13.9$ is the geometrical focus of the concave, their ratio being still as their dispersive powers, very nearly. Let us now assume $r = 7.5$, or any other quantity at option, and see by the proper theorem what R will be, to have a focus of 9.12 inches: to do this we have, by

No. 1. of our *practical theorems*, before given, $\frac{r F}{2r - F} = R$,

or, in figures, $\frac{7.5 \times 9.12}{2 \times 7.5 - 9.12} = R = 11.63$; hence

$r : R :: 7.5 : 11.63$, or as 1 : 1.55. In the next place, we must determine what is the longitudinal aberration arising from the figure of a lens, where the ratio $r : R$ is 1 : 1.55, which is most conveniently done by the general theorem of Huygens, which we have before exemplified, and which

stands thus; $\frac{27r^2 + 6rR + 7R^2}{6 \times r + R} \times T = A = 1.3614 \times T$.

viz. $\left. \begin{array}{l} 27r^2 = 27.0 \\ + 6rR = 9.3 \\ + 7R^2 = 16.8175 \end{array} \right\} \begin{array}{l} r + R = 1 + 1.55 = 2.55 \\ \text{multiplied by } 6 \\ \hline \text{value of numerator} \} = 53.1175 \\ \text{value of denominator} \} = 39.015 \end{array}$

Then $\frac{53.1175}{39.015} = 1.3614 \times T = A$.

Having now found $1.361 \times T = A$ of the convex lens, the value of T, which is the sum of the versed sines of the two intersecting curves of its surfaces, may be calculated by the square root, or by plane trigonometry, and will be found = .252, when the semi-diameter of the lens is 1.5, consequently $1.361 \times .252 = .3429$, is the absolute quantity of the spherical aberration of the convex lens; but 'T of the concave

TELESCOPE.

concave is by calculation .1653, and $\frac{.3429}{.1653} = 2.074$ is its

proportional aberration. But as the thickness, breadth, and geometrical focal length of every lens, of whatever form, must, from the properties of the circle, be in proportion to each other (see Martin's New System, art. 705.), 'F may be taken at once, instead of using T and 'T with their calculated values (which require some operations), and then the work will be greatly facilitated; thus $1.361 \times T \times 1.524 = 2.074 \times 'T = 'A$. Now, as this quantity 2.074 bears the same proportion to 1.361, as the focus of the concave does to the focus of the convex, it might be concluded that this would be the proper aberration to correct the aberration 1.361 of the convex lens; but this is not the case, for, first, the longitudinal aberrations arising from the figure are not in the *simple* proportion to the foci of the lenses respectively, neither is the quantity the same with the flint as with the crown glass. Martin asserts that the spherical longitudinal aberrations are to each other, in like lenses of different focal lengths, *inversely* as the *squares* of the foci respectively; consequently, in our example, these aberrations would be inversely as $F^1 : 'F^2$; or as $13.9 \times 13.9 : 9.12 \times 9.12$;

that is, as 193.21 : 83.174, or as $\left\{ \begin{array}{l} A \\ 1.361 : 0.585 \end{array} \right\}$; but

when Tulley took 0.585 = 'A, this aberration was found much too little; for when he had ground the lenses with curves to produce this aberration, he found that the eye-tube required to be drawn outwards more than inwards by the screw, from the true focal point, before the image disappeared, which is a proof that the concave had less than its share of aberration; it being considered as a test of good correction, when the image disappears at points of the tube equally distant from the point of distinct vision, accordingly as the tube is pushed in or drawn out from its focal point. And here was probably the difficulty that Martin experienced between his theory and practice. Neither was the aberration thus obtained in due proportion, when corrected by the simple ratio of the two divisors $2a : 2'a$, or 1.056 : 1.147, for the difference of the refractive powers; for as 1.147 : 1.056 :: 1.161 : 1.253; but $1.253 \times 'T = 'A$ was still too little for due correction. Though the telescope was achromatic by virtue of the ratio of the foci of the crown and flint lenses, yet there was a want of perfect *diffinition*, owing to the deficiency of aberration attaching to the concave lens. After a multiplicity of investigations, calculations, and practical trials, Tulley at length discovered a method of balancing the opposite aberrations, which he has continued to practise with success for years, and which is therefore no new project. The method is this: the value of 'A ($2.074 \times 'T$) being first determined from A, in the ratio of F : 'F, as above explained, the *correcting number* is thus obtained; if we call the square root of the cube of the refracted focus of the convex = x, the geometrical focus being taken = 1; and put also y for the square root of the cube of the refracted focus of the concave, when its geometrical focus is = 1; then $\frac{y}{x} = z$ is the correcting number,

by which the proportional aberration, before determined, must be *divided*, to gain the proper or *corrected* aberration,

now expressed by the symbols $\frac{'A}{z}$. In the instance before

us, the calculation will be $.947^3 = .8492781$, and its square root = .2914 = x; and $\sqrt{.872^3} = .2575 = y$; then

$\frac{.2575}{.2914} = .883 = z$, the correcting divisor, and also $\frac{'A}{z} =$

$\frac{2.074}{.883} = 2.348 = 'A$ corrected.

Having now ascertained the aberration $2.348 \times 'T$ of the concave lens, that will balance the aberration $1.361 \times T$ of the convex, we must proceed to determine the ratio 'r : 'R of the concave, that shall have exactly this aberration: to be able to do this without a table of aberration, requires an acquaintance with quadratic equations; for the proportion of the radii 'r and 'R must be investigated from the corrected aberration which we have now ascertained.

1st. We have $\frac{27r^2 + 6rR + 7R^2}{6 \times r + R^2} \times T = A$ (by

the general theorem) = $2.348 \times 'T$, as before found; but we make no distinction between r, R, T, A, and 'r, 'R, 'T, 'A, that we may simplify the symbols: this equation, by evolution of $r + R^2$ in the denominator, becomes

$\frac{27r^2 + 6rR + 7R^2}{r^2 + 2rR + R^2} \times \frac{T}{6} = 2.348 \times T$: now by putting

$R = 1$, there will be $\frac{27r^2 + 6r + 7}{r^2 + 2r + 1} \times \frac{T}{6} = 2.348$

$\times T$; or, dividing both sides by $\frac{T}{6}$, $6 \times 2.348 = 14.088$,

or $14.1 = \frac{27r^2 + 6r + 7}{r^2 + 2r + 1}$; and multiplying both by the

denominator, $14.1r^2 + 28.2r + 14.1 = 27r^2 + 6r + 7$: then subtracting equal quantities from both, there remains $22.2r + 7.1 = 12.9r^2$; and by transposition, $12.9r^2 - 22.2r = 7.1$ for the *quadratic*. Now to find the *root*, we have first

$r^2 - \frac{22.2r}{12.9} = \frac{7.1}{12.9}$; and adding the square of half the

co-efficient, $r^2 - \frac{22.2}{12.9}r + \frac{11.1^2}{12.9} = \frac{7.1}{12.9} + \frac{11.1^2}{12.9}$; there-

fore the root $r = \frac{11.1}{12.9} = \sqrt{\frac{7.1}{12.9} + \frac{11.1^2}{12.9}}$, and $r =$

$$\sqrt{\frac{7.1}{12.9} + \frac{11.1^2}{12.9}} + \frac{11.1}{12.9}$$

Lastly; to collect the aggregate of the values of r, we

have $\frac{7.1}{12.9} = .55$, $\frac{11.1^2}{12.9} = .74$, and $\sqrt{.55 + .74} =$

$\sqrt{1.29} = 1.135$; likewise $\frac{11.1}{12.9} = .860$; therefore 1.135

+ .860 = 1.995 = r, which was desired; and the ratio r : R, which we now put again 'r : 'R = 1.995 : 1; and which in Tulley's Table stands 2 : 1. After having thus determined the ratio of the radii 'r and 'R to be 2 : 1 very nearly, we must now find the rational geometrical focal distance of this concave by the fourth of our *practical theorems*

above exemplified; viz. from $\frac{2rR}{r + R}$, we first have

$\frac{2 \times 2 \times 1}{1 + 2} = 1.333$; and as the geometrical focus is known

to be 13.9, we have also $\frac{13.9}{1.333} = 10.428 = 'R$, and 10.428

TELESCOPE.

$\times 2 = 'r$; so that the four radii of the faces and the corresponding foci will stand thus; *viz.*

$r = 7.50$ } and $F = 9.12$, the geometrical focus of the
 $R = 11.63$ } convex lens.

$'R = 10.428$ } and $'F = 13.9$, the geometrical focus of the
 $'r = 20.856$ } concave lens.

$\Phi = 30.04$ the compound refracted focus of the telescope, according to the proper theorem.

We have now brought the calculations of our first example to a conclusion, accompanied by such explanations as may render it unnecessary to dwell so minutely on the following examples; and when we have gained these radii for a telescope of 30 inches focus, we have the means of making a telescope equally achromatic and distinct of any other length; for the ratios $r : R$ and $'r : 'R$, being once determined for crown and flint glafs of given refractive and dispersive powers, require only to be increased in equal quantities to suit the foci of the proposed telescopes, as in the subjoined table; and it may be proper to notice, that though the specific gravity has not been taken into the account in the calculations of this example, yet it is useful as an index to point out the ratio of the sines of incidence and of refraction, and of the dispersive powers to be used, when the specimens of glafs are selected by their specific gravities only, without an experimental trial by grinding.

The subjoined table is suitable for achromatic double object-glasses of various lengths; where $m : n$ in the crown-glass is as 1.528 : 1, and in the flint as 1.5735 : 1; their dispersive powers being 1 : 1.524.

TABLE I.—Radii of double Object-glasses in Inches.

Φ	r	R	$'R$	$'r$
6	1.50	2.326	2.086	4.171
12	3.00	4.652	4.171	8.342
18	4.50	6.978	6.256	12.513
24	6.00	9.304	8.342	16.684
30	7.50	11.630	10.428	20.856
36	9.00	13.956	12.512	25.027
42	10.50	16.282	14.598	29.198
48	12.00	18.608	16.684	33.369
54	13.50	20.934	18.770	37.540
60	15.00	23.260	20.856	41.712
72	18.00	27.912	25.025	50.054
84	21.00	32.564	29.196	58.396
96	24.00	37.216	33.368	66.738
108	27.00	41.868	37.540	75.080
120	30.00	46.52	41.712	83.424

In this table, R and $'R$ are the faces of the two lenses which come in contact, and r and $'r$ the external faces; and it will be seen that R , being a little longer than $'R$, the convex face, will approach the concave one very closely, but will not touch it, which is a necessary practical condition. When the aberration exceeds 1.666, which is that of $r : R$ when they are each = 1, or alike; then r exceeds R , and the lens must be reversed, or put in its worst position; which is the case in all our tables for double object-glasses with the flint-glass; otherwise the concave would not have had sufficient aberration for the convex.

In our next example it will not be necessary to do the work at full length, but only to give such an abridgment as will be intelligible to the reader who understands the process minutely explained in the preceding example. The density of different sorts of crown-glass seldom varies; but two specimens of flint can seldom be found to be alike. The greater the density of flint-glass, the more suitable it is for the purpose of making a concave lens of an achromatic object-glass, because the radii of both the lenses may be longer for the same compound refracted focus; and, consequently, the spherical aberration will be less than in glass that requires shorter radii to produce the same compound focus. If the form of the concave had been given, the convex would have been determined by a reversed operation, where the multiplier 1.524 would have been a divisor, and z a multiplier, &c.

Example 2.—Let it be required to form a double object-glass of 30 inches focal length, as before, with the same crown-glass for the convex, but with the densest flint, in which the ratio $m : n$ is as 1.599 : 1, and their dispersive powers 1 : 1.757?

In this example we have $1.056 = 2a$, or the divisor for the crown, as before, and $1.599 - 1 \times 2 = 1.198 = 2a$, or divisor for the flint; then $\frac{1}{1.056} = .94697 = F$ refracted, and

$\frac{1.757}{1.198} = 1.466 = 'F$, also refracted; and also $\frac{F \times 'F}{'F - F} =$

2.67, the ratio of the compound focal length, or what we called the *rational* compound focus; consequently, the ratio between F geometrical and the compound focus is in this example 1 : 2.67; and the ratio between the refracted foci of the separate lenses, to correct the colorific

rays, is $\left\{ \frac{F}{.94697} : \frac{'F}{1.466} \right\}$. With respect to the spherical

aberrations, which are next to be considered, we may in the first place determine the quantities x and y , and z the *correcting* divisor, which is derived from them, thus;

$\left\{ \frac{F}{\sqrt{.94697^3}} = .2914 = x \right\}$; and as $\frac{1}{1.198} = .834$, &c.

gives the refracted focus of the flint or concave lens, (F geometrical being = 1 in this case,) $\sqrt{.834^3} = .2408 = y$, and

$\frac{y}{x} = \frac{.2408}{.2914} = z = .826$, the *correcting* divisor required for

this refractive power of the flint-glass. In the next place,

$\frac{30}{2.67} = 11.23 = F$ (geometrical), and $11.23 \times 1.757 =$

19.73 = $'F$ (geometrical also). Let us here assume $r = 9$

inches, and then by the theorem $\frac{rF}{2r - F} = R$, we get

$R = 14.92$, and consequently the ratio $r : R$ will be 9 : 14.92, or 1 : 1.66 in its lowest terms. A double convex

lens

TELESCOPE.

lens ground with its radii in this ratio, will have its spherical aberration = $1.325 \times T$; to counteract which, the concave must have its proper aberration determined; and then the ratio of its radii must be investigated, that shall make a lens with this determined quantity of aberration. We have seen already that $A = 1.325 \times T$, therefore $1.325 \times 1.757 = 2.328 \times T = 'A$, the proportional aberration for 'F, considered as having the same refractive power as F; but the *correcting*

divisor must now be applied, and $\frac{'A}{z} = \frac{2.328}{.826} = 2.818$

is the corrected aberration, for which the radii ' r and ' R are now to be investigated. By putting ' $R = 1$, as before, and by working out the root of the quadratic arising from $\frac{27r^2 + 6rR + 7R^2}{6(r+R)^2} \times T = 2.818$, we shall have the

ratio ' $R : 'r = 1 : 3.075$. And, lastly, for the actual radii of the concave, we get, by our practical theorem $\frac{2rR}{r+R} = F$, $\frac{2 \times 1 \times 3.075}{1 + 3.075} = 1.51 = 'F$ rational, and $\frac{19.73}{1.51} = 13.06 = 'R$; as also $13.06 \times 3.075 = 40.15 = 'r$, the second side of the concave. Whence we now have

$$\left. \begin{array}{l} r = 9.00 \\ R = 14.92 \end{array} \right\} \text{and } F = 11.23 \text{ geometrical.}$$

$$\left. \begin{array}{l} 'R = 13.06 \\ 'r = 40.15 \end{array} \right\} \text{and } 'F = 19.73 \text{ geometrical.}$$

$$\Phi = 29.81 \text{ according to the proper theorem.}$$

It may be satisfactory to prove, that the geometrical quantities F and ' F , which we have here determined, will make Φ , the compound focus of the telescope, = 30 inches. But it will be requisite first to turn the geometrical foci F and ' F into the refracted foci, by their respective divisors, denominated $2a$ and $2'a$, viz. 1.056 and 1.198: thus, $\frac{11.23}{1.056}$

= 10.634 = F refracted, and $\frac{19.73}{1.198} = 16.479 = F'$ refracted; then by our theorem $\frac{F \times 'F}{F - F'} = \Phi$, we have

$$\frac{10.634 \times 16.479}{16.479 - 10.634} = \frac{175.237686}{5.845} = 29.81 = \Phi; \text{ and if}$$

the decimal had been carried farther in the geometrical foci, the compound focus would have been quite 30, as required. It may be for the benefit of practical men to subjoin a table similar to our preceding one, derived from the radii of curvature determined in this second example. And let it be understood by our readers, that in all our tables for the radii of curvature, the length of the telescope in inches is denoted by the figures in the first vertical column; and that the numbers in the same horizontal column with any given length, shew the proper geometrical radii of curvature for convex and concave lenses to construct such telescope.

The following table is suitable for double achromatic object-glasses of various focal lengths, where $m : n$ in the crown-glass is as 1.528 : 1, and in the flint as 1.599 : 1; and their dispersive powers as 1 : 1.757.

Example 3.—We shall now take the same crown-glass, with a flint-glass between the two extremes, which we have used, viz. in which $m : n$ is as 1.584 : 1, and their dispersive powers as 1 : 1.59; and let it be required to calculate a double achromatic object-glass of 30 inches focal length, as before?

Having already the divisor ($2a$) of the crown equal 1.056, we begin with getting that of the flint thus, $\frac{1.584 - 1}{1} \times 2 = 1.168 = 2'a$, or proper divisor; then $\frac{1}{1.056} = .94697 = F$ refracted, as before; and $\frac{1.59}{1.168}$

= 1.3613 = ' F refracted. Also $\frac{F \times 'F}{F - F'} = 3.111$, the rational compound focus; and 1 : 3.111 is the ratio between F geometrical and Φ . We have $x = .2914$ from our former examples, and to get y , we have $\frac{1}{1.168} = .856 = 'F$ refracted, when ' F geometrical is = 1; therefore $\sqrt{.856^3} = .2512 = y$; but $\frac{y}{x} = z$; hence $\frac{.2512}{.2914} = .862 = z$,

the correcting divisor. Again, $\frac{30}{3.111} = 9.643 = F$ geometrical, and $9.64 \times 1.59 = 15.327 = 'F$ in the same denomination. In this example we will take $r = 8$ inches; then, by the proper theorem $\frac{rF}{2r - F} = R$, we have

$$\frac{8 \times 9.64}{2 \times 8 - 9.64} = 12.12 = 'F, \text{ and } \frac{12.12}{9.64} = 1.515; \text{ consequently the geometrical ratio } r : R = 1 : 1.515. \text{ Also, from}$$

TELESCOPE.

from the general theorem of Huygens, we find $A = 1.374 \times T$, and $1.374 \times 1.59 = 2.184 \times 'T = 'A$ rational, which is yet to be corrected; then $\frac{2.184}{.862} = \frac{'A}{z} = 2.535$, the corrected aberration. By getting the root of the quadratic arising from this aberration agreeably to the general theorem, as before, the ratio of the radii $'R : r$ comes out $1 : 2.375$.

Lastly, by the theorem $\frac{2rR}{r+R}$ we get $\frac{2 \times 1 \times 2.375}{1 \times 2.375} = 1.407 = 'F$ rational, and $\frac{15.327}{1.407} = 10.89 = 'R$, and also $10.89 \times 2.375 = 25.864 = 'r$. We have, therefore,

$$\left. \begin{array}{l} r = 8.00 \\ R = 12.12 \end{array} \right\} \text{and } F = 9.643.$$

$$\left. \begin{array}{l} 'R = 10.89 \\ 'r = 25.86 \end{array} \right\} \text{and } 'F = 15.327.$$

Hence the next table is suitable for double achromatic object-glasses of various focal lengths, where $m : n$ in the crown-glass is as $1.528 : 1$, and in the flint as $1.584 : 1$; and their respective dispersive powers as $1 : 1.590$.

TABLE III.—Radii of double Object-glasses in Inches.

ϕ	r	R	'R	'r
6	1.60	2.42	2.18	5.17
12	3.20	4.84	4.36	10.34
18	4.80	7.27	6.53	15.52
24	6.40	9.69	8.71	20.69
30	8.00	12.12	10.89	25.86
36	9.60	14.54	13.06	31.03
42	11.20	16.97	15.24	36.20
48	12.80	19.39	17.42	41.38
54	14.40	21.81	19.60	46.55
60	16.00	24.24	21.78	51.72
72	19.20	29.08	26.14	62.06
84	22.40	33.93	30.49	72.40
96	25.60	38.77	34.85	82.73
108	28.80	43.63	39.20	93.10
120	32.00	48.48	43.56	103.44

Example 4.—Let us next take an example, in which plate-glass is substituted for crown, and let the sines of the angles of incidence and of refraction in it be as $1.504 : 1$, while $m : n$ in the flint is as $1.573 : 1$, and their dispersive powers $1 : 1.623$; and let the length of the telescope be required to be 30 inches, as before? Then $\frac{m-n}{n} \times 2 = 2a = 1.008$, is the divisor for the plate-glass; and

$\frac{m-n}{n} \times 2 = 2a = 1.147$, or a divisor for the flint; also $\frac{1}{1.088} = .992 = F$ refracted; and $\frac{1.623}{1.147} = 1.415 = 'F$

refracted. Again, $\frac{F \times 'F}{'F - F} = 3.318 = \phi$ rational; also

$\sqrt{.992^3} = x = .3124$, and $\left(\frac{1}{1.147} = .872\right) \sqrt{.872^3}$

$= y = .2575$; whence $\frac{y}{x} = \frac{.2575}{.3124} = .824 = z$. Like-

wise $\frac{30}{3.318} = 9.03 = F$, and $9.03 \times 1.623 = 14.65 = 'F$.

Put $r = 7.5$; then $\frac{rF}{2r - F} = R = 11.34$, and $\frac{R}{r}$

$= 1.51$, or $r : R :: 1 : 1.51$; hence A , by the general theorem of Huygens, $= 1.376 \times T$, and $'A = 1.376 \times 1.623 = 2.233 \times 'T =$ the aberration of the concave corrected for the difference of refractive power. The root arising from a quadratic equation of this aberration is $'r = 2.78$, when

$'R = 1$, consequently $\frac{2rR}{r+R} = 1.471 = 'F$ rational, and

$\frac{14.65}{1.471} = 9.96 = 'F$ geometrical; also $9.96 \times 2.78 =$

$27.68 = 'F$ geometrical. Thus,

$$\left. \begin{array}{l} r = 7.50 \\ R = 11.34 \end{array} \right\} F = 9.03 \text{ geometrical.}$$

$$\left. \begin{array}{l} 'R = 9.96 \\ 'r = 27.68 \end{array} \right\} 'F = 14.65 \text{ geometrical.}$$

TABLE IV.—Radii of double Object-glasses, with Lenses of Plate and Flint, in Inches.

ϕ	r	R	'R	'r

Example

TELESCOPE.

Example 5.—Let the ratio of the radii of the convex lens be 1 : 6, in which the spherical aberration is a *minimum*, and let the crown and flint glass be as in the first example for a telescope of 30 inches?

Then, by the same process, there will come out

$$\begin{aligned} r &= 5.32 \\ R &= 31.92 \end{aligned} \left. \vphantom{\begin{aligned} r &= 5.32 \\ R &= 31.92 \end{aligned}} \right\} F = 9.12, \text{ as before.}$$

$$\begin{aligned} 'R &= 12.60 \\ 'r &= 15.50 \end{aligned} \left. \vphantom{\begin{aligned} 'R &= 12.60 \\ 'r &= 15.50 \end{aligned}} \right\} 'F = 13.9, \text{ as before.}$$

This table is proper for glass of the same refractive and dispersive powers as in Table I., but with the spherical aberrations the least possible.

TABLE V.—Radii of double Object-glasses in Inches, where the Convex has a Minimum of Aberration.

Φ	r	R	'R	'r
6	1.05	6.38	2.52	3.10

108	19.14	114.91	35.28	55.80
120	21.28	127.68	37.80	62.00

In the preceding example, where the ratio of the two radii of the convex lens were given, r comes out = 5.32 in a thirty-inch telescope; and in like manner, when the aberration only is given, the ratio of the radii may first be determined by a quadratic equation, and then the other curves may be determined as they have been here, without any assumption of r in the convex lens. But in all cases the relative refractive and dispersive powers must be known previously to the calculations such as we have exemplified.

Example 6.—In this example let us take the same crown and flint glass as we did in the second example, and put $r = 7.5$, as in our first example; and then the radii will be as in the following table.

TABLE VI.—Radii of double Object-glasses in Inches.

Φ	r	R	'R	'r
6	1.50	4.47	2.91	6.12
12	3.00	8.94	5.82	12.24
18	4.50	13.41	8.73	18.35

120	36.00	36.96	36.52	117.20

TELESCOPE.

In this and the six preceding tables, the radii are calculated for an aperture of three inches for a focal distance of thirty inches; and the optician who may use any of them, with *similar glass*, may increase or diminish his aperture accordingly as the focal length is greater or less than thirty inches.

If we examine and compare the respective radii r and R , and also $'r$ and $'R$ of the convex and concave lenses in the preceding tables, which are all calculated by the same process that is used by Tully, and several of which have been used in practice, we shall perceive that a difference in the quality of the glass, as to *dispersive* and *refractive* powers, makes the curves of the lenses widely different; and that a small alteration in the assumed value of r , the first face of the convex lens, also produces a great alteration in the curves of the three other faces of the compound object-glass. For instance, if we compare the radii in Table I. with those in Table VI., where r is assumed equal, *viz.* 7.5, in both, and where the same crown-glass is used, and the *flint-glass alone* taken different, the former being No. 2. and the latter No. 1; the radii in the former are $r = 7.5$, $R = 11.63$, $'R = 10.43$, and $'r = 20.86$, in a telescope of thirty inches focal length; whereas in Table VI. there is $r = 7.5$, as before, but $R = 22.34$, $'R = 14.56$, and $'r = 30.58$; which curves are very widely different. And if we compare Table II. with Table VII., in both which r is again assumed equal, as well as the crown, while the two flints are *reversed*, *viz.* the former having No. 1. and the latter No. 2, the comparison will stand thus in telescopes of thirty inches focal length: in Table II. there is $r = 9.00$, $R = 14.92$, $'R = 13.06$, and $'r = 40.15$; but in Table VII. $r = 9.00$, as before, while R is 9.24 , $'R = 9.13$, and $'r = 29.30$. Hence it is manifest, that it is not only *useless* but *detrimental* to copy the radii of a double object-glass of even the best telescope that ever was made by any artist, unless the *refractive* and *dispersive* powers of both sorts of glass be *precisely the same*, in the given and proposed telescopes intended to be equally good: but when different specimens of glass are necessarily used by different artists, it is hardly to be expected that both the requisite qualities of each piece of glass will be found alike, or even sufficiently near a perfect similarity, to authorize the copying of the radii of a standard telescope, even if those radii could be measured by mechanical means with sufficient accuracy; but the measurement from the *solar focus* of a lens, as is usual, does not afford data for obtaining the *geometrical focus*, and from it the radii of curvature, unless the quantity $2a$ be previously known; though the converse operation, we have before seen, is not difficult to a practical optician. We have no hesitation, therefore, in condemning the practice of analysing a telescope for the purpose of copying it; for it is the certain guide to irrational constructions; and seldom will an instrument so made be free from either colours or indistinctness.

Neither is it safe to copy *tables*, such as those published by Dr. Brewster, in his edition of Ferguson's Lectures, of which the *forms* are also given under the article *ACHROMATIC Telescopes*, (in the Edinburgh Encyclopædia,) until the specimens of glass to be used are ascertained to have the same *refractive* and *dispersive* powers, as those from which the tables are calculated. On comparing these tables with the results of professor Robison's calculations, given in the Encyclopædia Britannica under the article TELESCOPE, we find not only that the basis of these tables is derived from this source, but that the calculations themselves are adopted, without further modification than what is necessary for adapting them to given focal lengths of the

compound object-glass. As professor Robison's article on our present subject has hitherto been considered to be the only article in our language that has disclosed the steps by which an *achromatic object-glass* may be constructed directly from mathematical calculations; it will be satisfactory to our readers that we should try what curves will result from Tully's practical mode of proceeding, when the same data are taken that Robison has used in one of his examples. In an example worked according to Boscovich's formula, the ratio of $m : n$ in the crown-glass is taken as 1.526 : 1, and in the flint, so high as 1.604 : 1; while the ratio of the dispersive powers, when converted into the proper terms, are

only in the ratio 1 : 1.65, or $1 : \frac{1}{.6054}$; let us see what

will be the curves of a thirty-inch telescope, when r is assumed = 9.7, and $R = 9.54$, according to Dr. Brewster's Table VI., derived from Robison's numbers $0.32325 \times 30 = 9.6975$, and $0.31798 \times 30 = 9.5394$.

As r is greater than R in this assumption, the convex lens is in its worst position, and the spherical aberration, A , determined by the general theorem of Huygens, will be $1.682 \times T$: and as the geometrical foci of the two lenses must be directly as their dispersive powers, and as T and $'T$ are inversely as those foci, we shall have $1.682 \times 1.65 = 2.775$ for the proportional aberration $'A$ uncorrected; then as the correcting number, for flint of 1.599 : 1, which is the most dense that Tully has met with, is .826, we may take this without apparent error for that of 1.604 : 1; and

then $\frac{2.775}{.826} = 3.26 = 'A$ is the *corrected* aberration of the

concave; and according to this aberration, the root of the quadratic will give $'R : 'r$ as 1 : 5.40; and by theorem $\frac{2rR}{r+R}$

the rational focus will be $\frac{2 \times 5.40 \times 1}{5.40 + 1} = 1.688$; then

having $r = 9.7$, and $R = 9.54$, by the same theorem we have F of the convex = 9.618, and $F \times 1.65 = 15.8697 = 'F$, or focus of the concave. Also we have

$\frac{15.87}{1.688} = 9.401 = 'R$, or shorter radius of the concave;

and $9.401 \times 5.4 = 50.76 = 'r$, or longer radius of the concave. Lastly, to obtain the compound focus Φ , we must reduce the geometrical focus of each lens into its refracted focus, by the proper divisors 1.052 for the crown, and 1.208

for the flint; then we shall have $\frac{9.618}{1.052} = 9.14$ for the re-

fracted focus of the convex, and $\frac{15.87}{1.208} = 13.04$ for the

refracted focus of the concave; and by the theorem $\frac{F \times 'F}{F - 'F}$

these numbers will give $\frac{9.14 \times 13.04}{13.04 - 9.14} = 30.53 = \Phi$.

We have now obtained numbers that will enable us to form the desired comparison; thus, according to Robison,

$$r = 9.7, R = 9.54, 'R = 9.54, 'r = 47.47;$$

but according to Tully,

$$r = 9.7, R = 9.54, 'R = 9.40, 'r = 50.7.$$

Also, according to Robison we have $F = 9.618$ and $'F = 13.25$ geometrical, and the compound focus $\Phi = 29.1$. But according to Tully, $F = 9.618$ and $'F = 15.8697$ geometrical, while the compound focus $\Phi = 30.53$.

TELESCOPE.

Now as $F : 'F :: 1 : 1.65$ (the respective disperse powers), let us see if either of these results will make an *achromatic* telescope: thus, as

$$\left\{ \begin{array}{l} F \quad 'F \\ 1 : 1.65 :: 9.618 : 15.8697 \end{array} \right\}$$

which shews that Tulley's foci are *exactly as the disperse powers*, and therefore would be *achromatic*, if the *disperse power* had been truly proportioned to the *refractive power*; but from long experience he knows, that the disperse power of flint-glass of the greatest density, compared with that of crown, which seldom varies, is not less than 1.759 : 1. Hence Robison's disperse power is in the first place taken too low; and in the next, allowing it to be truly taken, he has not preserved the two separate focal distances in such ratio, agreeably to that of the disperse powers, as will make an *achromatic telescope*. And this is further proved by the circumstance, that the compound focus does not come out exactly 30, which it will always do by Tulley's process, if the proportions are all *rational*. If we substitute the ratio 1.759 : 1, instead of 1.65 : 1, for the disperse power, which Tulley's table of disperse powers gives, to correspond with the refractive powers, when $m : n$ as 1.599 : 1; and if we take the convex lens of Robison in the worst position, as before, with $r = 9.7$, and $R = 9.54$, the radii of the concave, by Tulley's mode of calculating, will be $'R = 9.65$, and $'r = 68.04$, and the compound focus $\Phi = 25.6$; with which curves and focal length the telescope would be *achromatic*, and truly *corrected* for spherical aberration; but as R comes out a deeper curve than $'R$, these surfaces would come in contact at the centre, and therefore are not in a practicable form. Hence we infer that the construction of an achromatic telescope with Robison's convex lens in its *worst* position is impracticable, though a concave might be determined to suit it in its best position; *viz.* when its faces are reversed. There is, indeed, no form of a double convex lens, but a concave may be calculated to suit it, provided the curves come out in a practicable form; but, on the contrary, a concave may be fixed on that, in its worst position, (which is always its position in a double object-glass,) can have no convex that will match it. Martin has

shewn, that if the aberration of a given concave be $\frac{a}{b} \times 'T$,

then $\frac{a}{b} \times 'T \times \frac{6}{T} = \frac{4a}{b} = 6.42857$ will be a *minimum*;

whence $a : b :: 6.43 : 4 :: 16 : 10$ nearly. Therefore, when

$\frac{4a}{b}$ is *less* than 6.43, the problem will be impossible. For

instance, in a plano-concave lens, the aberration is $\frac{1}{2}$ of T , and $\frac{1}{2} \times 4 = 4.66$ only, which should not be less than 6.43; and therefore this lens cannot be used singly with a convex of any description; much less can a concave in its best form, where $r : R :: 1 : 6$, be used; for its aberration

$\frac{15}{14} \times T$ gives $\frac{4a}{b} = 4.284$ only. But either of these may

be used in their worst position, because then either of them will have aberration enough for any convex. And this previous consideration will enable the skilful optician to fix on a proper ratio of $'r : 'R$, before he proceeds to his calculation. Should it be asked, why we prefer Tulley's disperse powers to professor Robison's? our answer is this; that Tulley's were not gained simply by prismatic measurement of the spectrum, like Robison's, where some errors are obviously unavoidable; but have been corrected by repeated comparison of the focal lengths of the convex and concave lenses in the very best achromatic telescopes selected for the

purpose, where, when a high magnifying power was used, the least discolouration would have been observable; and as these foci are always in the same ratio as the disperse powers, no other method of determining these powers can have similar pretensions to accuracy.

When the convex and concave lenses are both ground and polished (see GLASS and GRINDING), they require some care in putting them properly into the tube, so that they may have their common axis coinciding with the axis of the eye-glasses, in order that every part of the field of view may be equally distinct and free from colour: and as there will always be some errors of workmanship, and as both lenses, but particularly the flint, may not be perfectly homogeneous, one of the lenses must be turned round in the common cell, till the faults of one lens are observed to correct those of the other as much as possible; which will be known when the vision is most distinct, or the object best defined. Should any colour remain about the edges of the object, the prismatic aberration is not corrected; and if indistinctness does not take place soon, and at equal distances from the point of distinct vision, when the eye-tube is moved in and out, the correction for spherical aberration is not perfect. A double object-glass is much more easily adjusted for a good central position, and for the counteraction of opposite errors of workmanship and imperfection of glass, than a triple one, and has moreover more light, in consequence of having but four reflecting surfaces; but as it does not admit of any change of the faces in the final adjustment, the lenses require to be both truly calculated and nicely worked, in order to make the practice correspond with the theory; which is probably the reason why triple object-glasses, that admit of changes in their positions, are most frequently made, particularly for short telescopes: besides, half a dozen of these lenses may be ground and polished at the same time; whereas, for a double object-glass, each lens requires to be ground and polished separately, and with the greatest care.

Triple achromatic Object-glasses.—After having explained the theory, and exemplified the construction of a double achromatic object-glass with great minuteness, we come now to treat of triple object-glasses, that shall have the achromatic property; but it will not be necessary to give so many examples, nor such minute explanation, as seemed requisite in our preceding part of this subject, seeing that the calculations for a triple object-glass are grounded on those that we have given for a double one, and do not materially differ from them. It will, however, be proper to shew how the compound focus of three lenses is determined, before we proceed to find the achromatic proportions of the respective radii.

First, we must have recourse to our *fundamental theorem*, (of Table I. of theorems for the refractive foci of lenses,)

viz. $f = \frac{p dr R}{dR + dr - p R r}$, where p is the reciprocal of

the refracting power of the medium employed, or of

$\frac{m - n}{n}$, the measure of that power, r and R the radii, as

before, and d the radiant distance. To apply this theorem to a system of glasses, as B, C, D, &c. which we propose doing, it is convenient to substitute, for the general expres-

sion $\frac{1}{p}$, the letters $a, b,$ and $c,$ as peculiar to each medium

respectively. Supposing now our three lenses arranged in the order B, C, D, with B next the radiant object (as in

K k

fg.

TELESCOPE.

fig. 12. Plate XXVIII.), we first determine the focus of B, which becomes in this case, if we substitute $\frac{1}{a}$ for p ,

$$F = \frac{1}{a} \times \frac{drR}{dR + dr - \frac{Rr}{a}} = \frac{drR}{adR + adr - Rr}$$

Now f , the focal distance of B, thus found, is manifestly the radiant distance of the second or middle lens C; and as the general theorem above referred to involves the radiant distance d , we have only now to apply that theorem again

to the second lens C, substituting, as before, b for $\frac{1}{p}$, and

for d , the quantity last found as the focus of B. This gives the compound focal distance of these two lenses B and C, which we will call ϕ ; and this again becomes the radiant distance of the lens D: therefore, lastly, the general theorem

is again applied to this lens, substituting c for $\frac{1}{p}$, and the

last found focus (ϕ) for d ; by which process, we arrive at the compound focus (Φ) of all the three lenses. In the application of these successive steps, it will be proper to attend to the signs of the quantities, where one of them, which in our case is the middle one, has its focus negative with converging rays. To exemplify this process in a triple object-glass for parallel rays, let B represent the outermost lens,

which we will consider as a double convex lens with $\frac{m-n}{n} = a = 0.53$, and r and R each = 10; let C be the double

concave of similar radii $'r$ and $'R$, and with $\frac{m-n}{n} = b = 0.6$; and let D be a plano-convex, and consequently R

infinite, but $r = 10$, as before, and $\frac{m-n}{n} = c = a = 0.53$:

then for the focus of B, putting $\frac{1}{p} = a$, we have $\frac{1}{a} \times$

$$\frac{drR}{dR + dr - \frac{Rr}{a}} = \frac{drR}{adR + adr - Rr} = \frac{drR}{adR - rR}$$

(adr being neglected, when R is infinite) = $\frac{dr}{ad - r}$; and

since d is also infinite with parallel rays, the expression becomes $\frac{r}{a} = F$, as in our first table of theorems for the

refracted foci of lenses, for the first lens B. This expression is now put for d , when we come to consider the theorem as

applied to C: here we have $\frac{1}{p} = b$, and the expression

$$\text{becomes } \frac{1}{b} \times \frac{drR}{dr + dR - \frac{rR}{b}}, \text{ or } \frac{drR}{bdr + b dR - rR};$$

then, as r is taken equal to R, it will be $\frac{dr}{2bd - r} = F$

of the lens C. Now, if in this expression we substitute $\frac{r}{a}$,

the focus of B, for d , we have for $\frac{dr}{2bd - r} \times \frac{r}{a} \times$

$$\frac{r}{2br - r} - r = \frac{r}{2br - ra} = \frac{r}{2b - a} \text{ for } \phi, \text{ the compound}$$

focus of B and C, or rather, as the rays fall converging on C, and $2b$ is more than a , = $\frac{-r}{-2b - a}$. Again,

this quantity will become d for the lens D, and putting the same substitution as before, in the general theorem

for D, where $\frac{1}{c}$ is put for p , we shall have $\frac{1}{c} \times$

$$\frac{drR}{dr + dR - \frac{rR}{c}}, \text{ or } \frac{drR}{cdR + cdR - rR}, \text{ or, when } r = R,$$

$$\frac{dr}{2cd - r}; \text{ hence we obtain } \frac{r}{2b - a} \times \frac{r}{2c \times \frac{r}{2b - a} - r} =$$

$$\frac{r^2}{2c \times r - 2b - a \times r} = \frac{r}{2c - 2b + a} = \Phi, \text{ or com-}$$

ound focus of all the three lenses, B, C, and D. Let us take, by way of example, three lenses as follow; viz.

B, a double convex lens of crown-glass, with its refractive power by experiment = 0.53 = a , and with equal radii, where r and R are each = 10; let the second lens C be a double concave of flint-glass, with the same radii, and of a refractive power = 0.6; and let the third lens D be a plano-convex of crown-glass, of a refractive power of 0.53 also, with $R = 10$ likewise; then, according to our last expres-

$$\text{sion } \frac{r}{2c - 2b + a}, \text{ we have } \frac{10}{2c - 2b + a}, \text{ or } \frac{10}{3c - 2b}$$

$$= \frac{10}{1.59 - 1.2} = \frac{10}{0.39} = 25.6 = \Phi. \text{ In this way}$$

the compound focus of any number of lenses may be determined, and the course of the rays might be traced in a geometrical figure out of one glass into another, until they come to their ultimate focus.

For instance, let us consider S and s , in fig. 12, to be two parallel solar rays incident on the first lens B, at the points b and b' : these rays, on entering, are bent towards the axis $cf\Phi$, and then from the points of emergence tend to their principal focus f ; but being intercepted by the double convex lens C, they diverge, after entering at c and c' , in a direction which points backwards to the virtual focus ϕ ; but in their progress, they again become incident on the plano-convex at the points d and d' , and are again refracted towards the axis, and meet in a distant point Φ , which is, therefore, the compound focus of all the three lenses. And if we conceive the parallel rays, S and s , to be pencils of solar rays, that *disperse* on entering the convex lens B, they will disperse in a contrary direction on entering the concave C, and will again, on entering the plano-convex lens D, have the excess of dispersion of C counteracted by a second opposing dispersion of D, and, instead of coming to unite at the distant points P and Q, to which they tended on entering D, they will meet, by virtue of the prevailing refraction of the two lenses B and D taken jointly, over the refraction of C taken separately, at the compound focus Φ , where the image of the sun will be formed; and if both the focal distances and radii of curvature of all the lenses were achromatically adjusted, as we shall presently direct, the image would be free from colours, and well defined.

The same determination of the foci f , ϕ , and Φ , in any combination, may, however, be obtained more conveniently in

TELESCOPE.

in practice, when r and R are unequal, from our former practical theorems, thus: let us determine the compound

focus of B and D by the theorem $\frac{F \times F}{F + F}$, as they have

each a positive focus, and call this focus $= \phi$ geometrical,

and then $\frac{\phi}{2a}$ will be ϕ refracted; and secondly, let 'F geometrical be turned into $\frac{F}{2b}$ for the refracted focus of the

concave C ; and then, by the theorem $\frac{F \times 'F}{F - 'F} = \Phi$, we

shall have Φ for the compound refracted focus of the triple object-glass, or length of the telescope: for example, taking

the same data as before, we shall first have $\frac{10 \times 20}{10 + 20} = \frac{200}{30}$

$= 6.66 = \phi$, and $\frac{6.66}{1.06}$, or $\frac{\phi}{2a} = 6.28 = \phi$ refracted;

and $\frac{10}{1.2} \left(\frac{F}{2b}\right) = 8.33 = 'F$ refracted: also, by the

theorem $\frac{\phi \times 'F}{'F - \phi}$, because 'F has a negative focus, we get

$\frac{6.28 \times 8.33}{8.33 - 6.28} = \frac{52.33}{2.05} = 25.53 = \Phi$, as was required.

We shall use this method of finding the compound focus ϕ of two lenses, and also Φ , the focus arising from all the three lenses, where it is to be understood that a , the symbol for the refractive power of both the crown lenses B and D , is taken the same; and that we express the refractive power of C , the concave, by the symbol b , as a substitute for 'a.

We must further premise, that when T , the thickness of each lens B and D , is not considered, we shall shew presently that the spherical aberration, arising from any single lens that receives the rays of light, may be diminished as $4 : 1$, by the combination of two lenses, to be substituted for that one. Bearing these premises in mind, we now proceed to the consideration of a triple object-glass, that shall have the due corrections for both the prismatic and spherical aberrations. It will greatly facilitate both our explanation and exemplification, if we suppose the two convex lenses B and D , having a compound focus $= \phi$, to be represented by a single lens E , with the same focus ϕ , but with a diminished aberration; for then we may proceed nearly as in our seven preceding examples; but reversing the process, when the concave has its radii given, to find the convex lens.

Example 8.—Let it be required to construct a triple achromatic object-glass of 30 inches focal length, with the same refractive and dispersive powers as in the first example; viz. with $m : n$ in the crown as $1.528 : 1$, and in the flint as $1.5735 : 1$; and with the dispersive powers as $1 : 1.524$; and let the two radii of the concave be each 13.9, so as to have 'F, as in the first example.

In the first place we have $r : 'R :: 1 : 1$, and, as we have seen above, $'A = 1.666 \times 'T$, by the general theorem of Huygens; in the next place, because the concave C is given to find the convex E , the correcting number z , found as before, becomes a multiplier, in a reversed operation, and we have $1.666 ('A) \times 'T \times .883 (z) = 1.4715 \times T = 'A$ corrected: we must also use the former multiplier 1.524 (the dispersive power, or proportional focus) as a divisor, and then we get

$\frac{1.4715}{1.524} = .9655 \times T = A$ of the substituted lens E , with

a focus $= \phi$; but there is no such small quantity of aberration in any one lens. Let us however see what the absolute aberration 'A will be, unconnected with the factor 'T, which factor we have determined, from the verified sines to the radii 13.9 and 13.9, to be $= .1653$; therefore $1.4715 \times .1653 = .2432 = 'A$ absolutely. Now we have seen, in the first example, that .252 is $= T$ of the proper convex; let us

now consider that $\frac{.252}{2} = .126$ is $= T$ in one of the lenses

B and D , which we propose to make in every respect similar, in order to have as few different curves, and consequently as few different tools, as possible; then, because .2432 is

the absolute aberration of C , the concave, we have $\frac{.24324}{.126}$

$= 1.93 \times T = A$ of either of the convex lenses; but T

is .126; therefore $1.93 \times .126 = .2432$ is the absolute

aberration of each convex lens, exactly equal to the absolute

aberration of the concave. But we have asserted, and

shall demonstrate hereafter, that when the thickness of the

lenses is neglected, a proper combination of two lenses,

placed at a certain distance from each other, will diminish the

aberration belonging to one four times, and even when the

distance $= 0$, this will be nearly the case: now we have

$.9655 \times T = A$ in the lens E of equal focus, let us leave

out A , and multiply by 4, and we have $4 \times .9655 = 3.862$

very nearly, the sum of the aberrations (without T) of the

two convex lenses B and D , taken together; viz. 2×1.93

$= 3.86$; but yet the absolute aberration of each separate

convex lens (T being considered) is exactly equal to the

absolute aberration ('T considered) of the double concave.

This relation of the respective aberrations being once estab-

lished and confirmed by practice, which Tulley affirms to

be the case, simplifies the complex business of calculating a

triple object-glass: for the sum of the absolute aberrations of

the two convex lenses of like glass, must be always equal to

double the absolute corrected aberration of the concave

alone, in order to have a due correction for spherical aber-

ration, and consequent indistinctness. Hence, when the fo-

cal distance, ϕ , of the two convex lenses B and D is in the

same proportion to 'F, the focal distance of the concave,

that their separate dispersive powers are relatively to that of

the concave B , the relative radii of either B or D , or of

both, may be varied at pleasure, provided that the sum of

their absolute aberrations remain equal to double the absolute

aberration of the concave C , and provided that ϕ , their

compound focus, be not altered. But we have not yet ad-

justed the two focal distances so as to make the object-glass

achromatic, and ϕ , or the compound focus of the three, to

be equal 30 inches. From an equation of the aberration

$1.93 \times T$, or from $.2432$ absolutely, we find the ratio of

$r : R$ in each lens to be as $1.34 : 1$, which is also agreeable

to Tulley's tables, from which this ratio may be had by in-

spection; also the rational geometrical focus for these num-

bers is 1.145. Now according to our first example, we have

seen that when 'F = 13.9 in a telescope of 30 inches focal

length, F will be 9.12, when there is only one double con-

convex lens; but here we have two lenses to produce $9.12 = \phi$,

and therefore, as both lenses are to be alike, we have 9.12

$\times 2 = 18.24 = F$ for each separate focus; therefore

$\frac{18.24}{1.145} = 15.93 = R$ of each, and $15.93 \times 1.34 = 21.35$

TELESCOPE.

= *r*; and the result of our calculation will stand thus; *viz.*

First convex B $\left\{ \begin{array}{l} r = 21.35 \\ R = 15.93 \end{array} \right\} F = 18.24, \text{ and } A = 1.93$
 $\times T = .2432.$

Concave C $\left\{ \begin{array}{l} 'r = 13.9 \\ 'R = 13.9 \end{array} \right\} 'F = 13.9, \text{ and } 'A = 1.4715 \times 'T = .2432.$

Second convex D $\left\{ \begin{array}{l} r = 21.35 \\ R = 15.93 \end{array} \right\} F = 18.24, \text{ and } A = 1.93$
 $\times T = .2432.$

Also - - - $\left\{ \begin{array}{l} F \times F \\ F + F \end{array} \right\} = \phi = 9.12$

And - - - $\left\{ \begin{array}{l} 'F \times \phi \\ 'F - \phi \end{array} \right\} = \Phi = 30.0$

It is hardly necessary to observe, that the quantities T and 'T are here given in *numbers*, for the sake of illustration; but when the quadratic equation is worked, those symbols may be exterminated, and their values involved in the process.

A table of radii for triple object-glasses, in which the two convex lenses of crown-glass, and the one of flint, have respectively the same refractive and dispersive powers as in Table I. and 'r = 'R.

TABLE VIII.—Radii of triple achromatic Object-glasses.

Φ	B Convex.		C Concave.		D Convex.	
	r	R	'r	'R	r	'R
6	4.27	3.19	2.80	2.80	4.27	3.19
12	8.54	6.38	5.60	5.60	8.54	6.38
18	12.81	9.56	8.40	8.40	12.81	9.56
24	17.08	12.74	11.20	11.20	17.08	12.74
30	21.35	15.93	13.90	13.9	21.35	15.93
36	25.62	19.11	16.70	16.70	25.62	19.11
42	29.89	22.30	19.50	19.50	29.89	22.30
48	34.16	25.48	22.30	22.30	34.16	25.48
54	38.43	28.67	25.09	25.09	38.43	28.67
60	42.70	31.86	27.80	27.8	42.70	31.86
72	51.24	38.22	33.40	33.40	51.24	38.22
84	59.78	44.60	39.00	39.00	59.78	44.60
96	68.32	50.96	44.60	44.60	68.32	50.96
108	76.86	57.34	50.10	50.10	76.86	57.34
120	85.40	63.72	55.60	55.60	85.40	63.72

Example 9.—Let it be required to construct another triple object-glass of 30 inches focal length, with crown and flint-glass exactly similar to what was used in the last ex-

ample; but let the radii of the concave be unequal; *viz.* 'r : 'R :: 1 : 1.23, and in the best position?

In this example we propose to abridge the work thus; first, 'A = 1.507 × 'T and z = .883, and $\frac{'A}{z} = \frac{1.507}{.883}$

= 1.33 × 'T = 'A corrected; then $\frac{1.33}{1.524} \left(\frac{'A \text{ cor.}}{'F \text{ rat.}} \right) =$

.873 × T for the proportional aberration of the substituted lens E, as before; which is an impossible quantity. The focus of this substituted lens, as in the last example, is 9.12, and consequently 9.12 × 2 = 18.24 is again the focus of one of the two convex lenses to be used, that of the concave

being, as before, 13.9 (for $\frac{13.9}{1.524}$ is = 9.12); whence 'r

and 'R will be 12.6 and 15.5 respectively. T, as before, is = .126, and 'T = .1653 (by calculation); hence 'T × 1.33 = .2198 is the *absolute* aberration of the concave lens, as well as that of each of the two convexes of 18.24 focus;

therefore $\frac{.2198}{.126} = 1.745 \times T = A$ of one of those lenses,

and the root of the quadratic arising out of this equation of A, gives the ratio of the radii, where R is unity, thus; as R : r :: 1 : 1.1; and the rational focus, by the proper theo-

rem, is 1.048; consequently $\frac{18.24}{1.048} = 17.40$ is = R of each

convex lens, and 17.40 × 1.1 = 19.14 is = r; so that we have now the subjoined results; *viz.*

Convex B $\left\{ \begin{array}{l} r = 19.14 \\ R = 17.40 \end{array} \right\} F = 18.24, \text{ and } A = 1.747$
 $\times T = .2198.$

Concave C $\left\{ \begin{array}{l} 'r = 12.60 \\ 'R = 15.50 \end{array} \right\} 'F = 13.9, \text{ and } 'A = 1.33$
 $\times 'T = .2198.$

Convex D $\left\{ \begin{array}{l} r = 19.14 \\ R = 17.40 \end{array} \right\} F = 18.24, \text{ and } A = 1.747$
 $\times T = .2198.$

Also - - - $\left\{ \begin{array}{l} \phi = 9.12 \text{ for the compound} \\ \text{focus of B and D.} \end{array} \right.$

And - - - $\left\{ \begin{array}{l} \Phi = 30.0 \text{ for the compound} \\ \text{focus of B, C, and D.} \end{array} \right.$

The following is a table of radii for triple object-glasses, where the refractive and dispersive powers are as in the last example, but where the radii of the concave are unequal, *viz.* 'r : 'R :: 1 : 1.1.

TELESCOPE.

In like manner, any number of tables might be computed for the focal lengths of a triple object-glass, where the lenses have given refractive and dispersive powers, and where the radii assumed for one of the lenses are taken at pleasure; but it will be always desirable to fix on a concave lens first in a triple object-glass, notwithstanding we have shewn that it is better to assume a convex one first, where a double object-glass is calculated: for by attending to this direction, the optician will find that counteracting aberrations will be within his reach; and though he may fix on radii in the assumed lens that will not be the best in practice, yet, by changing the ratio of the assumed radii, he will find practicable lenses that will answer his purpose. In our tables of triple object-glasses, the numbers come out very convenient for practice; for in each, both sides of the convex lenses have longer radii than either face of the concave has got, so that there will be no point of contact, in the middle of any of the curves, when they are placed contiguous to one another; and in Table IX. there is just difference enough, between the radii of each of the convex glasses, to allow one of them to be reversed, if it is found that the errors of workmanship, or imperfection of the glass, should require such correction, when the object-glass comes to be finally adjusted. Indeed all the surfaces might be calculated to be a little different from one another, and then there would be the option of eight changes in the final adjustment: but if the glass is homogeneous, and the work well performed, it will always be found best to adhere to the positions for which the lenses have had their radii calculated.

Neither is it desirable, in a good achromatic object-glass, to use varnish of any description, as has been recommended.

As we have shewn that professor Robison's data, and the calculations founded on them, do not produce curves proper for an achromatic double object-glass, we will conclude this part of our subject by examining if his calculations for a triple object-glass are any better adapted for practice. In Dr. Brewster's Table V. (Appendix to his edition of Ferguson's Lectures, vol. ii. p. 418.) a thirty-inch triple object-glass is calculated, according to professor Robison's report of the radii used by the London artists, to have $r = 18.84$, (printed by mistake 18.34,) $R = 22.47$, r and R each 17.37, and the second convex the same as the first; where, as before, the ratio $m : n$ in the crown is taken as 1.526 : 1, and in the flint as 1.604 : 1, and the ratio of the dispersive powers as 1 : 1.65. If these numbers will make an achromatic object-glass, we shall have 1 : 1.65 :: F : F exactly; i. e. the ratio of the dispersive power will also be the ratio of the geometrical focal distances, agreeably both to theory and practice; but we have, by the theo-

$$\text{rem } \frac{2rR}{r+R}, \frac{2 \times 18.84 \times 22.47}{18.84 + 22.47} = \frac{846.6696}{41.43} = 20.495$$

for the focus of one convex lens, and therefore $\frac{20.495}{2} =$

10.247 for the compound focus of the two; also we have the focus of the concave = 17.37 in the table, the radii being equal; hence we have as 1 : 1.65 :: 10.247 : 16.90, instead of 17.37; therefore the object-glass is not duly corrected for the prismatic aberration. This conclusion, which is intelligible by every common reader, corroborates our former inference respecting the want of achromatism in the double object-glasses made from Robison's calculations; but let us pursue the enquiry a little farther, and see what focal distance will accord with these numbers: the refrac-

$$\text{tive power of the convex being } .604 = a, \text{ we have } \frac{10.247}{2a}$$

= 9.74 for the refracted focus thereof; and the refractive

$$\text{power of the concave being } .526 = b, \text{ we have } \frac{17.37}{2b} =$$

14.38 for its refracted focus, and by our theorem $\frac{F \times F}{F - F}$

$$= \Phi, \text{ we have } \frac{14.38 \times 9.74}{14.38 - 9.74} = \frac{140.0612}{4.64} = 30.18, \text{ \&c. for}$$

the focal length of the object-glass; which is much nearer to the proposed length than the focus of the double object-glass was which we before examined. If we calculate this triple object-glass according to our method, as practised by Tulley, we must begin with 16.9 as the proper focus for the concave, of which we disregard the negative sign, as of no importance in our mode of calculating; we shall then have as 1.65 : 1 :: 16.9 : 10.247, and this ratio must not be compromised, on any consideration, as being the achromatic ratio, on a supposition that the refractive and dispersive powers, as above stated, are in natural proportion; then as the radii r and R are assumed equal, the aberration of the concave will be

$$1.666 \times T, \text{ and } \approx .826; \text{ therefore } \frac{1.666}{.826} = 1.376 = A$$

corrected; and $\frac{1.376}{1.65} = .834 = A$ of the substituted single

lens E, which, as before, is an impossible quantity to be in one lens; but this being doubled, will be $1.668 \times T$ for the proper quantity of each lens; or multiplied by 4, will be a proper

TELESCOPE.

proper quantity for the sum of both the convex lenses; then 'T being found = .136, and T = .112 in each convex, we shall have A = 1.668 × 2 × .112 = .1871 for each convex, and 'A = 1.376 × .136 = .1871 also, for the concave, and consequently the ratio of r : R as 1.01 : 1; then by using the proper theorems, as before directed, these radii will come out r = 20.57, and R = 20.37 in each convex, while the concave will have each of its radii = 16.9, as originally assumed; and if the dispersive was great enough for the refractive power, as above specified, not only would the object-glass be *achromatic*, but its focal length would be = 30. But we find the geometrical F = 10.24, and re-

$$\text{fracted } F = \frac{10.24}{1.056} = 9.696, \text{ and } \frac{F}{2a} = \frac{16.9}{1.198} = 14.107 =$$

$$'F \text{ refracted, and } \frac{F \times F}{F - F} = \Phi, \text{ gives } \frac{14.107 \times 9.696}{14.107 - 9.696} =$$

$$\frac{136.781}{4.451} = 31 \text{ very nearly; and hence we infer, that the}$$

dispersive and refractive powers are *irrational* in this calculation, and the excess in the focal length is double the quantity with these two convex lenses, B and D, to what we found it with one, in a double object-glass, in our former examination. We are not however disposed to depreciate the mathematical labours of a man, whose memory will always be dear to every lover of science, and whose article TELESCOPE in particular has obtained the encomium of an eminent contemporary mathematician; but we have felt it our duty to point out the source of inaccuracy, which, by entering into the data, has affected the result of long and tedious calculations, and may have given much trouble to many, as we know it has done to some opticians, who have attempted to copy those results in practice. The learned professor has indeed stated, as he proceeds, that the value of certain appreciable quantities has been neglected, to simplify the process; and if those quantities had affected the focal distance more, and the ratio of the radii r : R, and also that of F : 'F less, the resulting prismatic and spherical corrections might have been more perfect, even with a defect of dispersive power, than we now find them. We have not room, however, to enter farther into particulars.

From Dr. Brewster's experiments, made in his "Treatise on New Philosophical Instruments," it appears that the *green* ray is not always in the *middle* of the solar spectrum, and that with rock-crystal it is at the opposite side of the middle from what it is in glass; hence Tulley infers, that if glass could be found of the same dispersive power as rock-crystal has, the intermediate colours might be corrected as well as the extreme colours; and that the secondary spectrum would disappear. To effect this improvement, the convex lens of rock-crystal must be at one side of the concave of flint, and the convex of crown or other glass, with equal dispersive power to that of the crystal, must be at the other side. This object is worthy of the optician's future consideration and pursuit.

Celestial achromatic Eye-pieces.—We have already explained, in the former part of this section, how the focus of two glasses, placed at a given distance from each other, may be ascertained, and also what is the focus of a single imaginary lens that shall be equal to them both in power: we propose therefore presently to return to the same figure, (fig. 8. Plate XXIV.) in order to shew what the advantage will be in point of *distinctness*, which is as essential a quality in an eye-piece as power. But, in the first place, let us suppose in fig. 10. the points 1, 2, and 3, so many points of an ob-

ject, of which the image is formed at F, after passing through any lens AB; then as the point 1 has rays issuing from it, that fall on every part of the lens, and as these rays are differently refracted at different distances from the axis, both towards A and towards B, there will be several images of this point at the focus F, lying contiguous to each other; but the rays that come to a focus, after passing in and near the central part of the glass, will form their images very closely together, so as very nearly to coincide. The same will be true of the points 2 and 3 separately considered, under the same circumstances, so that while the single lens AB continues to produce both prismatic and spherical aberrations, there will be a confusion or *indistinctness* in the image, arising from a promiscuous mixture of a number of contiguous and nearly coincident images arising out of the spherical figure of the lens, as well as fringes of colour arising out of the dispersion of the differently refrangible rays. This indistinctness is more considerable in a lens used as an object-glass, than as an eye-piece; because the image formed by it becomes an object to be viewed by means of the eye-piece, and therefore any distortion, confusion, or colouration that exists in the image, will be *magnified* by the eye-piece; and the greater the magnifying power, the greater will be the evil produced thereby. To obviate this consequence, which will exist partially, even when the best compound object-glass is used that art can accomplish, the single eye-glass has been laid aside, and a system of glasses substituted, that will admit of a high power in the eye-piece, without a proportionate increase of indistinctness or of colour in viewing the image. The first arrangement of two glasses, as a substitute for one, to be used as a celestial eye-piece, where inversion of the object is not material, was calculated and applied by the ingenious Huygens, who, not aware that the prismatic aberration could be cured by an opposition of *dispersive* powers, according to Dollond's noble discovery, devised the method of reducing the quantity of spherical aberration by *division*; and the result of his investigations was, that two plano-convex lenses, (which have each but little aberration in their best positions,) when placed at such a distance from each other that their focal points, for parallel rays, might coincide, would have such a compound focus, as would not only greatly increase the power, but still more diminish the spherical aberration. An arrangement of this sort was put into the hands of W. Molyneux by Mr. Flamstead in the year 1686, of which Molyneux determined the compound focus, depending on the radii of curvature of the two glasses and the distance between them, in the manner we have above explained. But the first mathematician who gave the *rationale* of the advantage to be derived from a combination of lenses, as they have reference to the spherical aberration, was sir Isaac Newton, whose method of explaining it Martin has given in his New Elements of Optics, part i. p. 27, thus: "Let NBM (fig. 9.) be the spherical surface of a plano-convex lens NGB; C the centre; CB the radius or semi-diameter taken in the axis; AN an incident ray; and NK the same refracted, cutting the axis produced in the point K. Also let F be the focus of parallel rays which pass through the glass infinitely near to the axis: let FD be a perpendicular to the axis in the point F, then will KF be the curve or difference of the focal distance of parallel rays which are incident near the axis, and at the distance GN, the semi-aperture of the lens. This is called the *aberration* of the extreme ray in *longitude*. Again, let any ray (an) be incident on the other side the lens, at the distance bG, the refracted part of this ray, nd, will intersect the other refracted ray ND in the point Q, at the perpendicular distance QO from the axis. This

TELESCOPE.

is called the *lateral error*, or the *aberration in latitude*. It is evident from the figure, that as the ray (*an*) approaches the extreme ray *AM*, the point of intersection *Q* will approach the axis; and when *an* coincides with *AM*, the point *Q* will coincide with the point *K* in the axis; and it is as obvious that the point *Q* will coincide with *F*, when the ray (*an*), approaching the axis *aB*, at last becomes coincident with it: therefore there is one position of the ray (*an*), in which it will cut the ray *ND* in a point *Q*, which will make *QO* a *maximum*, or the greatest of all. If we take the arc *Bm = Bn*, and *BM = BN*, the rays incident on *m* and *M* will intersect in the point *P* on the other side, and so make *PQ = 2 QO*; and it is also plain, that all the rays which fall on the lens between *N* and *M* are refracted through the space *PQ*. Now *PQ* is the diameter of the *least circular space* possible, in which *all the rays* can be congregated, because there will be some ray (*an*) that will meet the extreme ray *ND*, at the distance $QO = \frac{1}{2} QP$ from the axis. Hence it follows, that the circular space is the *focus*, or place of the *image* of an object, belonging to parallel rays incident on the lens *NM*. Further, by reason of similar triangles *KOO*, *KFD*, and *NGK*, we have $QO : KO :: DF : KF :: NG : GK$. But it is demonstrable, (see *Philos. Britannica*, 3 edit. p. 58. art. 14.) that when *QO* is greatest, then $KO = \frac{1}{2} KF$, and also that *KF* is always $\frac{2}{3}$ of *GB*, the thickness of the lens; so then $KO = \frac{2}{3} GB$, and consequently $GK : GN :: \frac{2}{3} GB : QO$, whence
$$\frac{2 GB \times GN}{8 GK} = OQ;$$
 whence *PQ*, the diameter of the circle of aberration, is known for any given lens.

“It has been demonstrated, that the error *PQ* will always be proportioned to $\frac{NG^3}{BC}$; so that when the radius is given, the error will be as the cube of the aperture directly: and when the aperture is given, the said error will be as the square of the radius inversely. It has also been demonstrated, that when the convex side of the lens *NBM* is turned towards parallel rays, the error *KF* will be but $\frac{2}{3}$ of the thickness of the lens *GB*, and therefore near four times less than in the other case; for $\frac{2}{3} GB : \frac{2}{3} GB :: 54 : 14$, which is almost as 4 to 1.

“It has been further demonstrated, that the aberration *PQ* is as the square of the sine of refraction (the sine of incidence being unity) in all media of different refractive powers: thus if a lens of the same focal distance and aperture were made of glass and water, and suppose those sines in glass to be as *m* : *n*, and in water as *m* : *n*; then will *PO* in the glass lens be to the same in the water lens as *m* : *m*², or the area of the circles of aberration, and of course the indistinctness of the object will be as the refractions *m* and *m* of the media.

“Whatever has been observed with regard to convex and plano-convex lenses, will hold good in concave and plano-concave ones. And in both sorts, it is supposed that all of them have the same focal distances, apertures, and thicknesses, while we are comparing their respective aberrations.

“Hence it is very evident, that if rays proceed from any point, as (*a*) at an infinite distance to a lens *NM*, (*fig. 10.*) the image of that point will not be a point, but the area of a circle, whose diameter is *PQ*; and, therefore, that point cannot be distinctly represented, but will be rendered indistinct and confused in proportion to the area of the said circle of aberration in the lens, as it is the image of this circle (or dilated point) that is impressed on the retina, and excites the idea of the point in the mind.

“Hence it appears also, that the points in the surfaces or

substances of bodies cannot be perfectly and distinctly seen, as each of them will be dilated into a sensible area; and such as are contiguous, as 1, 2, 3, will have their confused images all blended together nearly in the same space, *viz.* in the circle of aberration, the diameter of which is *PQ*.

“Therefore the stars, which as to sense are only lucid points, will appear to have some magnitude (and not as points) in the focus of the best sort of telescopes, even supposing there were no other cause of confusion or indistinct vision, besides what resulted from the spherical figure of the lens.

“Now, if the error from a spherical surface, or, which is the same thing, the *indistinctness* of vision, depending on, and commensurate with, the spherical aberration of a lens, is as the square of radius inversely; the *distinctness* of vision, on the contrary, will be as the *square* of the radius directly; and, therefore, if, by means of two glasses, we can get the view of an object, where the radii of the glasses bear a greater proportion to their respective apertures, than the radius of a single glass of equal magnifying power does to its aperture; it is evident the distinctness of that view will be promoted in proportion to the square of that ratio.

“For example, suppose (*fig. 8.*) *F - D = y*, or *OF*, to be the focal distance of the lens *GH*, so that the focus of each of the lenses *NM* and *GH* falls on the same point *F*; then, by the proper theorem, we have $x = \frac{1}{2} F$, or $Qf = \frac{1}{2} CF$: also, since in this case we have $F : y :: x : f$, therefore $f = \frac{1}{2} y$, or $Of = \frac{1}{2} OF$. Now, since we have the same optic angle *GFO* by both the glasses, as by the single one *EE*, the ratio of the radius *OF* to the aperture *GO*, or of the radius *CF* to the aperture *NC*, is double the ratio of *Of* to *OG*, or of the radius *Qf* to the aperture *EQ*, and therefore the *distinctness* of vision by both the lenses is *four times* greater than that by the single lens *EE*.

“The same thing may be demonstrated from the consideration, that the aberration *PQ* is, in the same glass, always proportioned to the cube of the semi-aperture *EQ*, or sine of half the optic angle *EfQ*; and that in small angles (as in the glasses of telescopes, &c.) the sine *EQ* is nearly as the angle *EfQ*. The aberration, therefore, being as the cube of that angle, it is plain, if we make the same angle by two refractions instead of one, the quantity of the aberration will be greatly lessened, since the sum of the cubes of the parts will be much less than the cube of the whole; and when the parts are equal, the *sum* of the cubes of *each* will be but a *fourth part* of the cube of the *whole*. Thus, if the whole angle *EfQ* be as 1, the cube thereof is 1; but the half is $\frac{1}{2}$, the cube of which is $\frac{1}{8}$, and twice that, $\frac{2}{8} = \frac{1}{4}$, which is as the aberration arising from the two halves, and is therefore but a *fourth part* of the whole.

“This is evidently the case when the optic angle *GfO* ($= EfQ$) is made by two refractions, by the two lenses *NM* and *GH*, so posited, that the focus of each may fall on the same point *F*; for then the angle $GfO = LGf$, which is composed of the two angles $LGf = TNf = GfO$, (by reason of the parallel lines *TN*, *LG*, and *FC*,) which is the part made by the lens *NM*. Also the angle *Fgf* is the refraction of the ray *NG*, or second refraction of the ray *AN*; and since, in the present case, $Of = fF$, and *Of* in small angles is equal to *Gf* nearly; therefore the angle *GFO* is equal to the angle *Fgf* very nearly, those angles being in the same ratio with the equal lines *Gf* and *fF*, when they are not large; and the optic angle $GfO = GfO + Fgf$; consequently the aberration *PQ* is but a fourth part so great by the two lenses *NM* and *GH* together, as it is by lens *EE* alone.

“But to render this theory general for any position or form

TELESCOPE.

of the lenses NM and GH, it is evident, since the aberration is lessened by dividing the optic angle, that the *distinctness* of vision will be thereby promoted; and because each of the angles contribute thereto in proportion to its magnitude, the joint effect of both parts, or angles G F f and f G F, will be as the product or rectangle under both, or as the rectangle of the lines Of and fF; but, according to our former notation, $Ff = F - D - f$; and $Of = f$; consequently $Ff - Df - ff$ will be every where as the distinctness of vision by the two lenses, above that of a single lens of the same magnifying power.

“Let the degree of distinctness thus obtained be represented by $G = Ff - Df - ff$; when this is a *maximum*, or the greatest possible, the fluxions thereof will be nothing; *viz.* $Ff - Df - 2ff = 0$, whence $F - D = 2f$; or $FO = 2Of$; that is, $Of = fF$, or the angle G F f = f G F, in the *best* position of the lenses, as before demonstrated.

“Consequently, since in that position we have shewn the distinctness of vision to be four times as great as by a single lens, this will be the whole effect of a combination of two glasses, and it may be shewn that three glasses will produce nine times the distinctness, and so on in proportion to the *square* of the number of glasses; but then if we consider the evil to be remedied is but small, and the damage we sustain in *loss* of light and irregularity of refraction through so many lenses, we may soon make the remedy worse than the disease; and every thing considered, it appears probable that two lenses are better than a greater number, particularly for a celestial eye-piece.”

By similar reasoning we may explain the advantage of any other eye-piece, as *Boisovich's*, when we know the radii, the position, and the distance of the lenses that compose it. The *Huygenian* eye-piece, which we have said has the foci of the two plano-convex lenses, as 3 : 1, at the distance of 2, with 1 next the eye, and the curves exterior to the eye, is peculiarly adapted for a reflecting telescope that has only the spherical aberration; but for a refracting telescope, though achromatic, a little deviation from this form was found necessary to correct the remaining prismatic aberration also. On enquiring of the best opticians, we learn that the final adjustment of distance between two lenses, in a celestial achromatic eye-piece, is made from trials in the tube of the telescope it is intended for; because this distance, and indeed the ratio of the radii of the two lenses, will greatly depend on the state of convergence of the rays, when they are incident on the first surface of the interior glass; and this state will depend on the focal length of the telescope, conjointly with the aperture, and achromatism of the object-glass: so that it would not answer any good purpose to give a table of dimensions, which might mislead rather than assist the young optician in his practice. The form of an achromatic celestial eye-piece, composed of two plano-convex lenses, is represented in *Plate XXVIII. fig. 13*, where the distance exceeds the focal length of the lens 1 next the eye, and in which consequently the image is between the lenses; which is the usual construction when the heavenly bodies are viewed without any reference to the measurement of angles; but as the place of the image will vary in some degree with a change of distance, in taking terrestrial measures, there is another form, commonly called *Ramsden's*, which is more suitable for micrometrical measurements; because the image, being beyond both lenses, (counting from the eye,) keeps its place, as it regards any scale, wire, or spider's line, that may be used in a micrometer: this form is given in *fig. 14*, of the same plate, and has the position of the interior face reversed, so that the plane face may be parallel to the contiguous image to be viewed: these two lenses are sometimes alike, and

always nearly so, in focal length; and the distance between them is less than the focal length of either by such a quantity, that the compound focus falls just beyond the flat face of the interior lens 2, where the image and scale, wire, or line coincide in due adjustment for vision. This form has likewise the advantage of reduced aberration, and is sometimes called the *positive* eye-piece, in opposition to the other form, which is therefore by some astronomers called the *negative* eye-piece. This positive eye-piece is also best adjusted to the instrument of which it is destined to form a part; and either lens may exceed the other in focal distance in a small degree, as circumstances may require.

When this eye-piece is used with a transit instrument, zenith sector, equatorial, or circular instrument for taking altitudes, it is convenient to put a diagonal reflector between the lenses, and to have the eye-lens in the *side* of the tube, for the purpose of taking observations in high altitudes, or even in the zenith. This form is seen in *fig. 15*, of the same plate, and is called a *prismatic* eye-piece.

The *terrestrial* eye-tube is that which gives an *erect* position to the object, as viewed in a telescope of the refracting sort, to which only it is applied, though it might be applied to the *Cassagrainian* reflector with equal advantage. It has been seen that, originally, this eye-piece was composed of three similar lenses, placed from each other respectively at the sum of their focal distances, as in *fig. 3. Plate XXV*. In this arrangement the magnifying power is not increased, unless the lens, T U, nearest to the eye has its focal distance diminished more than the rest: but the aberration that would arise from the figure of the field-lens C D, is diminished about *nine* times, if we disregard their thickness, *viz.* as the square of the number of glasses employed between the image I M, and the eye at K; consequently, the advantages derived from this eye-piece of Rheita are two-fold; for, first, it gives an erect position to the object; and, secondly, it greatly diminishes the quantity of spherical aberration, and consequently produces a corresponding distinctness; but the *power* of this eye-piece is *simply* that of one of the three lenses. To effect an increase of power at the same time that the two preceding advantages are preserved, various arrangements of three, four, and even of five lenses, have been made for the purpose of constructing a good terrestrial achromatic eye-tube; and the ingenuity of a *Dollond* and of a *Ramsden* has been exercised successively to accomplish the desired object. These arrangements, so far as the diminution of spherical, and even of prismatic aberration was concerned, have been understood and explained; but the total power arising out of a number of lenses differently shaped, and placed at different *distances* relatively to each other, has not been so clearly explained; and it should seem, from the manner in which such arrangement has been described by different authors, that the result has generally been ascertained practically rather than theoretically; which indeed must in some degree be the case whenever *power*, or, which is the same thing in effect, whenever actual focal distance, simple or compound, is to be accurately determined. We will not proceed upon the intricate plan of tracing the passage of a refracted pencil of rays through various lenses of different refractive qualities, and placed at various intervals, until they arrive at their last focus, or place of the image of a distant radiant body; neither do we propose to follow the more familiar but less instructive method of simply giving in figures the radii and relative distances of three, four, or five lenses, that shall compose an achromatic eye-tube; but, avoiding each extreme, we shall describe the most improved eye-tube for erect position, upon the principles of a *compound microscope*, which instrument this tube really

TELESCOPE.

really is of itself, and that of the best construction. We have referred an account of the *theory* of the *compound microscope* until we arrived at this article, on purpose to shew the intimate connection that it has with the refracting telescope, which, it will be seen presently, is also the case with a compound *reflecting* microscope, that composes a portion of both the Gregorian and Cassegrainian telescopes. First, let $a b$ (*Plate XXV. fig. 8.*) be considered as an object to be magnified for examination by a compound microscope of the simplest construction; let $d f$ be the small object-glass, of which i is the solar focus; then as the radiant object $a b$ is at a small distance from the lens $d f$, beyond its solar or principal focus, the incident rays coming from it will converge slowly after passing through this lens, and consequently the conjugate focus at the other side of the lens will be remote, as at $A B$, where an inverted image, $A B$, of the object $a b$ will be formed; and if the object is brought nearer to the solar focus i , the image $A B$ will recede with a linear amplification, for it always subtends the same angle at e , the centre of the object-lens, that the object subtends at the same point; it is therefore obvious, that the linear amplification of the image, compared with the length of the object, will be as their respective distances from the object-

lens, *viz.* as $\frac{C e}{c e}$; and, consequently, the farther the image

recedes, that is, the nearer the object is brought towards the solar focus i , the more it will enlarge, which principle is the basis of both the magic lantern, and solar as well as lucernal microscope. Let us call the ratio of the object to its image $1 : 5$, as in our figure; then if $D F$ be a double convex eye-glass, placed so that this image, $A B$, may be in its principal focus, the rays of light coming from it, now considered as a *radiant*, will, by passing through this lens, become *parallel*, in which state they will enter the eye at I , and after converging to a new focus on the retina, will there make a picture of the image of the object, but in a reversed position. The principal pencil of rays coming from d and f of the object-lens, will meet at C , the centre of the image, and diverge till they come to the eye-lens $D F$, where they are made parallel, and where they define the size of the eye-hole in the cap of the eye-piece; while the angle of vision will be $G E H = B E A$. In this situation, the image $A B$ is magnified by the eye-glass inversely as its focal distance, that is, as many times as $F C$ is contained in $e C$; for the visual angle $B E A$, subtended by $B A$, exceeds the angle $B e A$, subtended by the same line $B A$; and, consequently, its opposite angle $b e a$, subtended by the object, is in the ratio of $C e : C E$; and also, when $C E = c e$, in the ratio of $C e : c e$; and the whole amplification will consequently be by compounding the ratios = $\frac{C e^2}{C E \times c e}$. But in this construction the field

of view is small, though the power is great; and the colorific effect of the prismatic aberrations, as well as the indistinctness and distortion of the figure of the object, are fully experienced. To do away these impediments to a pleasing view of the object, a second lens was introduced into the eye-piece, as $M N$, in *fig. 11. Plate XXIV.*, the original intention of which was, principally, to enlarge the *visible area*, or circle of vision, which it did effectually, while, at the same time, it diminished the power, and in some measure the spherical aberration, though the latter advantage does not seem to have been contemplated; and in this state the compound microscope remains in the present ordinary construction, one of the three lenses, $d f$, being the *object-glasses*; the second being the *amplifier* $M N$; and the third the

eye-glass $G H$. Now if we compare the compound celestial eye-piece in *fig. 8*, before described, as having the same power with the single imaginary lens $E E$ in the same figure, we shall see that the only difference in the two arrangements is, that the image in *fig. 11.* is between the lenses, but in *fig. 8.* beyond them both. We have demonstrated the advantages of the combination in *fig. 8*, and have shewn that those advantages will continue, if the image be formed between the lenses; and also that making the distance between the glasses to exceed the focal distance of the eye-glass, will bring the image into this intermediate situation, as is actually the case in the best achromatic telescopes, with both the celestial and terrestrial eye-pieces; particularly when the wire, or cobweb micrometer, is not used. If then we consider the object $a b$ in *fig. 11.* to be the small or *primary* image of a distant object, formed in the focus of the achromatic object-glass, the image $A B$ will become the image of an image, or *secondary* image, in a contrary position; and this is the one actually viewed in the terrestrial tube of a telescope. Let us in the next place conceive the terrestrial tube to have only the three glasses that compose the arrangement of the compound microscope, and it is obvious that the image $a b$ will be rendered as distinct, and as much enlarged in it, as the object $a b$, of similar dimensions, would be in the like compound microscope. Thus have we a terrestrial eye-piece with an arrangement of *three* glasses, which magnifies greatly, and, so far as the pair of eye-glasses are concerned, is achromatic; but with respect to the object-lens $d f$, (which might indeed have been made achromatic by a balance of contrary *disperse* powers, on Dollond's plan of an object-glass for a telescope), there remained room for improvement; and this has been effected by the same principle of *division* of the aberrations, that contributed to the improvement of the celestial eye-pieces with two lenses.

Plate XXVIII. fig. 15. shews a combination of two plano-convex lenses, that perform the office of one double convex lens in a compound microscope, or terrestrial eye-tube, in which the lens A is placed next the object in a microscope, or image in a telescope, with its plane face outwards, and the lens B is placed at a distance from A , that exceeds the focal length of either of the two lenses, and that is also greater than the distance between the two eye-glasses; but the proportions vary with circumstances. In the patent micrometrical telescope of Harris, in which the eye-tube is $7\frac{1}{2}$ inches long, the focus of the eye-glass is $1\frac{1}{2}$; that of the field-glass, or amplifier, $1\frac{1}{2}$, and the distance $2\frac{1}{2}$; while the lenses of the eye-end are both menisci; the outermost lens having a focus of $1\frac{1}{2}$, and the inner lens one of 1.2 or $1\frac{1}{5}$, at a distance of $2\frac{1}{2}$. This novel form of a terrestrial eye-tube is found very good for a short telescope, and answers equally well for any variable length of focal distance of the patent object-glasses; and when the telescope has its focal length invariable, the difference between each separate pair of lenses may be varied at pleasure, and then the *power* of the whole combination will vary with the variations of this distance. In all other telescopes of the refracting kind, the two eye-glasses, as well as the pair of lenses at the remote end of the terrestrial tube, near the primary image, are all plano-convex, as we have shewn; and that combination which suits a short telescope, will generally suit a long one; but frequently that which is made purposely for a long one, will not suit a short one. A very good 12-inch terrestrial eye-tube, for a day and night telescope of two feet length, that we lately examined, has the proportions in the eye-tube somewhat different from telescopes with larger power; the eye-lens has a focus of 2 inches; the amplifier $3\frac{1}{2}$, at a distance of 3 inches; and the third and fourth lenses are

TELESCOPE.

respectively $3\frac{1}{2}$ and 3, at a distance of $4\frac{1}{2}$; the fourth lens being that next the primary image. The convex portion of all the four lenses is turned to the centre of the tube in all the terrestrial eye-pieces, except when Ramsden's, or the positive eye-piece, is substituted for the common or negative one. Another good day eye-tube, of $9\frac{1}{4}$ inches length, has the first, or eye-lens, $1\frac{1}{4}$; the second, or amplifier, 2, at a distance of $2\frac{1}{4}$; the third 3, reversed as usual; and the fourth $2\frac{1}{2}$, at a distance of $3\frac{1}{2}$. When a great power is wanted, the celestial eye-piece does very well for the eye-end of the terrestrial tube; and it would be an advantage to every good telescope, if they were fitted for this purpose by an adapter, such as we shall have occasion to describe in our fifth section; for then each telescope would have a great variety of powers; and if the celestial eye-pieces were screwed into a separate tube, instead of a simple adapter, the power might be varied at pleasure, in any proportion, by altering the distance between the two separate pairs of lenses, as we shall hereafter shew has been done by the writer heretofore, in his micrometrical measurement of distances in the last section of this article.

But to resume the consideration of our compound microscope (*Plate XXIV. fig. 11.*), we now see that the lenses CD and df combine in such a way, that the object ab , instead of being a little out of the focus of the single lens df , is a little way out of the compound focus of the two; and a circular piece of metal, perforated in the centre, called a diaphragm, is fixed in the tube, at the separate focus of the lens df , to exclude the coloured rays arising from the prismatic dispersion of this lens; and then the rays of least dispersion, that pass through this hole, enter the lens CD near its centre, and, therefore, have afterwards but little spherical aberration; on which account it is obvious, that the image in the microscope, or secondary image in the telescope, will be *distinct and colourless*; and it is very extraordinary, that while improvements are daily meditated in every mechanic art, the addition of a second lens, to diminish the aberrations, is not yet made to the object-end of the compound microscope, though the same thing has been done in the terrestrial eye-tube of an achromatic telescope, which not only answers precisely the same purpose, but is in fact itself an *achromatic compound microscope*.

After having gone through our explanation of the practical forms of both the double and triple achromatic object-glasses, and also of the various achromatic eye-tubes, which we have endeavoured to render intelligible to young opticians, we shall finish this long section by giving a short account of the different arrangements of the glasses of an achromatic telescope depending on these various forms, as we have already done with respect to the old telescopes, represented by *figs. 1, 2, and 3. Plate XXV. Fig. 4.* shews the arrangement of a double object-glass in conjunction with a negative eye-piece of two lenses, with the image between them, the power of which is simply the compound focal length of the object-glass A, divided by the compound focal length of the eye-lenses B and C. This arrangement is that of the best achromatic telescope with a celestial eye-piece, and, being shorter than the terrestrial telescope, is more conveniently managed. When the eye-piece has a slip of graduated mother-of-pearl, contrived by Cavallo, and divided by Mr. Barton, at its diaphragm, it makes an useful micrometer for measuring small angles: and when this eye-piece is taken out, the wire or cobweb micrometer may be screwed in, instead thereof; and then, if the telescope is of a good size, an angle within its reach may be measured with great accuracy. With this celestial telescope the object is inverted, and the light will be directly as the area

of the aperture, and inversely as the magnifying power. *Fig. 5.* gives the arrangement of the lenses in a terrestrial achromatic telescope with a triple object-glass; in which A is the object-glass, B the eye-lens, and C the amplifier, or field-lens of the eye-piece BC; D is the third lens, that diminishes the aberration of the fourth lens E, which, in a compound microscope, is called the object-lens. This is considered the best construction of a terrestrial telescope. The power is equal to the compound focus of the object-glass, divided by the compound focus of the eye-piece BC, when the quotient is multiplied by the first part of the microscopic power of the lenses E, D, which part will vary with the distance between the two pairs of lenses. The arrangement in *fig. 6.* differs from that in *fig. 4.* only in the eye-piece, which has here the image beyond it. Also the arrangement in *fig. 7.* differs in like manner from that in *fig. 5.*; and what we said respecting power and light of those lenses, is equally true of these. The eye-pieces of the telescopes in *figs. 6. and 7.* are those of the wire and cobweb micrometers.

3. *Theory of cata-dioptric Telescopes.*—When the image of a distant object is formed in any telescope entirely by reflected rays meeting at a focus, this image is properly *catoptric* (from the Greek word *κατοπτρον*, *speculum*); but when it is formed partly by reflection and partly by refraction of the rays, in coming to a focus, it is then *cata-dioptric*, that is, both catoptric and dioptric; and as the image cannot be viewed without an eye-glass, all reflecting telescopes are promiscuously called *cata-dioptric*.

Before we describe any of the different constructions of a telescope where reflection is concerned, we will explain the principles on which the catoptric theorems are founded, and give a small table of those theorems that determine the focus under different circumstances, as we have already done with respect to the dioptric theorems; at the same time referring our readers for farther information on this subject to the articles CATOPTICS, MIRROR, and SPECULUM. In *Plate XXVI. fig. 8. Astronomical Instruments*, let the curve GE be considered as a portion of a convex speculum, formed from the centre C, and CA or CE its radius; then suppose DA to be a ray of light proceeding from D, the radiant point, in the axis of the speculum, and falling on the point A, from whence it is reflected in the direction of the line Ae, tending in a contrary direction to a point F, its *virtual focus*, in the axis of the speculum behind the vertex E: then put $DE = d$; CA or CE = r ; CF = z ; and $FE = f + z = r = CE$. Now if we suppose the point A to be very near to E, a point in the axis, the angles at D and C will become very small, and will, consequently, have the same proportion to each other as their opposite sides AC and AD have; but $AC = AE$, and DA may be taken = DE without any sensible error; hence there will be this analogy, $ADC : \angle C : DE :: r : d$. Produce now CA to I, and IA will be perpendicular to the face of the speculum in A, the point of reflection; and, therefore, the angles DAI and IAF will be equal. But $DAI = \angle AC$, and $IAF = \angle CAF$, as being respectively opposite, therefore $\angle AC$ is equal $\angle CAF$: also $\angle AC = \angle ADC + \angle ACD = r + d$, and consequently the angle $\angle CAF = r + d$. Again, in the triangle CFA, when the point A is near the axis at E, the angles at A and C will be very small, and will have the same proportion to each other as their opposite sides FC and FA, and the angle $\angle FAC : \angle FCA :: FC : FA$: but in this case FA may be esteemed = FE, and therefore we have $\angle FAC : \angle FCA :: FC : FE :: z : f$. But we have seen that the angle at C is as DA or DE, that is, as d , and

TELESCOPE.

d , and also the angle FAC as $r + d$; therefore we have as $f : z :: d : d + r$; and by composition of ratios, $f + z : f :: 2d + r : d$; but $f + z = r$ ∴ $r : f :: 2d + r : d$; then by multiplying the extremes and means together, we have the equation $dr = 2df + fr$, and dividing by $2d + r$,

there results the theorem $\frac{dr}{2d+r} = f = EF$. This may

be considered as the *fundamental theorem in catoptrics*, from which the focus may be determined in any speculum, concave, convex, or even plain, whether the rays fall on it diverging, parallel, or converging; and from a due variation of the symbols and signs, as the case may require, we have all the variety of theorems for finding the focus contained in the subjoined table.

TABLE for finding the Focus of Rays reflected by any Speculum.

Rays.	Convex.	Concave.
Diverging -	$\frac{dr}{2d+r} = f.$	$\frac{-dr}{2d-r} = f.$
Parallel - -	$\frac{r}{2} = f.$	$\frac{-r}{2} = f.$
Converging -	$\frac{-dr}{-2d+r} = f.$	$\frac{dr}{-2d-r} = f.$

To illustrate the utility of this little table, let it be required to determine the respective foci of two specula, both ground and polished, on tools of 30 inches radius, when the radiant object is placed at 300 feet distance, one speculum being convex, and the other concave? In the first place, as the distance is less than infinite, the rays will come diverging from a luminous point; and, therefore, with respect to the convex speculum, we must use the theorem

$$\frac{dr}{2d+r} = f, \text{ which in figures will stand thus, } \frac{300 \times 2.5}{2 \times 300 + 2.5} = \frac{750}{602.5} = 1.245 \text{ feet, or } 14.94 \text{ inches for the required}$$

focus; but for the concave speculum, the theorem $\frac{-dr}{2d-r}$

$= f$ (or $-f$, because the focus and centre of the curve are on the same side of the speculum) will give us these numbers,

$$\text{viz. } \frac{300 \times 2.5}{2 \times 300 - 2.5} = \frac{750}{597.5} = 1.255 \text{ feet, or } 15.06$$

inches for its focal distance; and in like manner may the proper focus be determined for any other radius and distance, however the rays may be circumstanced when they fall on the speculum: whenever they come converging or diverging from a first to a second speculum, the focal point, real or virtual, must be considered as the radiant, and its distance reckoned accordingly.

These theorems, however, imply that the speculum is already made, whereas in many practical cases, the focus is first assumed, and the proper radius of convexity or concavity is required, or, which is the same in effect, the radius of the tool is required that shall be proper for forming the requisite curve. For instance, let it be required to form a tool of such a radius, that an image of any very remote object may be formed, by a speculum ground and polished

to its dimensions, at the distance from its reflecting surface of just 18 inches? In this case, the rays must be considered as parallel, because the object is remote; and, indeed, it is always for a remote object that the curve of a large speculum is formed; consequently the theorems $\frac{r}{2} = f$, and

$\frac{-r}{2} = f$, or $-f$, will be suitable for the required purpose, in both which $2f = r$; therefore $18 \times 2 = 36$ will be the proper radius of either the convexity or concavity of the tools to be used. If the ray had been diverging, and the focus affirmative, or behind the speculum, for a convex speculum the theorem arising from transformation would have been $\frac{2df}{d-f} = r$; and for a concave $\frac{2df}{f-d} = r$; but

in the case of a negative focus, or focus before the speculum, the former would have been $\frac{-2df}{d+f} = r$, and the latter $\frac{-2df}{-d-f} = r$. In like manner, the distance may be determined from the radius and proper focus being given; for, supposing the focus affirmative, with a convex speculum, the transformed theorem for diverging rays will be $\frac{rf}{r-2f} = d$, and with a concave $\frac{fr}{2f+r} = d$: but when the focus is

negative, the former will be $\frac{-fr}{r+2f} = d$, and the latter $\frac{fr}{2f-r} = d$. Hence, when any two of the terms f , r , and d are given, the third may be readily determined.

Thus, in the case of a convex speculum with diverging rays, if we put $d = r$, we shall have $\frac{r}{3} = f$; when $d = \frac{1}{2}r$, then $\frac{r}{4} = f$; when $d = \frac{1}{3}r$, then $\frac{r}{5} = f$; and when $d = \frac{1}{4}r$, then $\frac{r}{6} = f$: from which results we

see, that the points D and F both approach the speculum in a regular manner, till at last they will coincide at its vertex; and the same will be the case with a concave speculum, when the rays are converging, except that the focus is negative, or on the same side with the centre of convexity.

Also, when a convex speculum is used with converging rays, or a concave with diverging, when $2d = r$, f will be infinite; or, which is the same thing, the rays will be reflected parallel, as is the case in reflecting lamps; and, generally speaking, the focus of any concave or convex speculum may be made to fall in a given point, accordingly as the radiant object is made to approach to or recede from its principal focus with parallel rays; and wherever the focus is made to fall, there an image is formed of the object by reflection, in the same wonderful manner as we have had occasion to mention before, when speaking of its formation by refraction.

Likewise the connection between D, the radiant point, and F, the focus, is so intimate, that they may at any time change places without error; that is, when D is the radiant, F will be the focus; but if F is taken as the radiant, then D will be the proper focus in all cases.

In order to shew what proportion the length of an image, formed in the focus of reflected rays, will bear to the length

TELESCOPE.

of the object which it represents, let DE (*fig. 9.*) be a portion of a convex speculum, C its centre, V the vertex, O B an object, and I its image; and let it be required to find the proportion that the object, or line BO, bears to the image, or line IM. From the centre C, let the perpendicular CA fall on the object or radiant; and from its extreme points O, B, draw OC and BC, to meet the speculum in the points D and E; and do the same in *fig. 10.*, where the curve DE represents a concave speculum: then the line AV will be the axis, in some part of which the rays proceeding from the points O and B will meet, and the points of interfection will be the foci respectively. From O, let a ray OV pass to the vertex of the speculum, so as to make the $\angle FVA = \angle OVA$, then will VF be the reflected ray, which tending to the point I, in the axis CO, shall there form the image of the point O of the radiant. In like manner, the ray BV will be reflected in the direction VG, and intersecting the axis CB in M, will there depict the point B of the said radiant; and thus all the intermediate points lying between O and B will be represented between I and M, and a complete image of OB will be formed at IM. If we suppose the object at a great distance, and consequently small, the arc ED of the speculum will be very minute, and not sensibly different from a right line, and consequently will be parallel to the radiant BO, because CA is perpendicular to both BO and ED. Also, since the distances OD, AV, and BE, are very nearly equal, from their contiguity, it is plain that the focal distances DI, Va, and EM, will also be nearly equal; and, therefore, the image IM will be very nearly a right line, and parallel to the radiant OB, as well as perpendicular to CA.

Now from the nature of reflection, we have $\angle BVA = \angle AVG = \angle aVM$; therefore, $\angle OVA + BVA = \angle aVI + aVM$; namely, $\angle OVB = \angle VM$; so that the radiant, or object BO, and its image IM, are seen under the same angle from the vertex of the speculum. But the triangles AVO and aVI are similar, for the $\angle OVA = \angle aVI$, and the angles at A and a are both right angles; therefore, $VA : Va :: AO : aI$. For the same reason, $VA : V a :: AB : aM$; so that $VA : Va :: OA : AB : Ia + aM :: OB : IM$; or, in words, "the distance of the object is to the distance of its image, from its vertex V, as the length of the object is to the length of the image."

From the analogy here deduced, it is easy to form theorems, that shall determine either *d*, *f*, or the proportion O : I, when O is the length of the object and I of the image, when the two others are given. For we have given

$O : I :: d : f$, and consequently $\frac{1}{O} = f$; but our funda-

mental theorem was $\frac{dr}{2d+r} = f$, consequently $\frac{Id}{O} =$

$\frac{dr}{2d+r}$, and for $2dI + Ir = rO$; and $2dI = O -$

Ir ; consequently for a convex speculum, the theorem will

be $\frac{O - Ir}{2I} = d$; and for a concave, where *r* is negative,

it will be $\frac{Ir - Or}{2I} = d$. But if the focus be required

to be negative in a convex, the theorem will be $\frac{-Or - Ir}{2I}$

$= d$; and in a concave, where *r* and *f* are both negative, it

will be $\frac{Or + Ir}{2I} = d$. If *r* be required in a convex

speculum, when *d* and O : I are given, the theorem will be

$\frac{2Id}{O - I} = r$, and in a concave $\frac{2Id}{I - O} = r$; but if the

focus is required to be negative, the first will be $\frac{-2Id}{O + I}$

$= r$; and the second $\frac{2Id}{O + I} = r$.

Lastly, when *d* and *r* are given, to find O : I, we shall have this analogy for a convex speculum O : I :: $2d + r : r$; and for a concave, O : I :: $r - 2d : r$. But if the focus be negative, for a convex, it will be O : I :: $-2d - r : r$; and for a concave, O : I :: $2d - r : r$; so that, as we have said, when any two of the three terms are given, the other may be determined by calculation. By way of exemplification, let it be required to find the radius of a concave speculum, that shall make the image of an object, placed at 100 feet, as 1 : 60, in front of the speculum. Now *f* being in this case negative, we have the theorem, as before specified,

$\frac{2Id}{O + I} = r$, or, in figures, $\frac{2 \times 1 \times 100}{60 + 1} = \frac{200}{61}$

$= 3.28 = r$, nearly; or if *r* be given, and *d* required, the

theorem $\frac{Or + Ir}{2I} = d$ will give $\frac{60 \times 3.28 + 1 \times 3.28}{2 \times 1}$

$= \frac{200.08}{2} = 100.04 = d$; and if 3.28 had been the

exact radius, the distance would have come out exactly 100.

If the image and object had been given equal, they would both have fallen exactly at the centre of concavity of the mirror; which coincidence affords a ready method of determining the radius of concavity of any speculum, by means of a luminous point used as an object, and brought so that its image will exactly coincide with it. It is hardly necessary to add here, that a concave speculum forms an inverted and magnified image; and that a convex one makes it erect, and at the same time diminishes it.

We have before shewn how the aberration of the rays of light may be calculated, when reflected to a focus by a speculum of a spherical figure, when the rays are parallel before they suffer reflection; and it has been demonstrated, that for such rays a parabolic curve is the best suited for correcting such aberration, particularly when the image is formed by only one reflecting surface; but when there is a second or small speculum, either concave or convex, employed in forming a secondary image, or in assisting to form the primary one, a parabolic curve will not be the best for correcting the aberration of the rays; because each speculum will have its own aberration; and the practical optician can employ his skill in producing suitable specula for counteracting each other's errors, with respect to the united effect of their separate aberrations, better than the calculating theorist can pretend to direct; for the moment he screws his eye-tube alternately out and in, beyond and short of distinct vision, he knows the nature of the curves of his specula, and whether the indistinctness arising from aberration is the consequence of too much or too little curvature at the vertex of the large speculum, and can make the final alteration accordingly. This practical dexterity, arising out of experience, supercedes the necessity of tedious mathematical calculations, where some part of the data must necessarily be assumed; and it is much to be wished, that practical men, who have

excelled

TELESCOPE.

excelled in this particular, and in other practical niceties, would initiate their successors in the secrets that promoted their excellence, that posterity may benefit from their successful labours; which could not have been Mr. Short's wish, when he deliberately provided for the destruction of his best tools, after he no longer wanted them.

The circumstances that led to the construction of a reflecting telescope did not arise out of chance, as is supposed to have been the case with the dioptric, but out of the difficulty of avoiding the *indistinctness* produced by aberrations of both kinds; and the first arrangement that would probably occur, would be that of a speculum opposed to the eye of the observer, whose head in that case would intercept the incident rays, and prevent their falling on the speculum, unless it were made of an unmanageable diameter. To avoid this inconvenience, Gregory, who was the first to undertake the arduous task of a new construction, devised the expedient of opening a hole in the centre of the large speculum, sufficiently large to admit of the rays that came reflected a second time from a smaller speculum without a central perforation: it would naturally occur to him, that if this second speculum was not larger in diameter than the central hole of the large speculum, no incident light would be intercepted by it, when the rays came parallel, but what would have passed through the central hole of the speculum. This consideration brought the eye to the same end of the tube in which the large speculum was placed, and thus freed the aperture from all obstacles to the free admission of light; but whether the small speculum at first tried was a plain one, or concave, is not of importance to ascertain; it is sufficient for our purpose to know, that a concave one was ultimately adopted, and probably from the property which it possesses of varying the magnifying power to a considerable extent.

We have already said that Gregory's construction of the reflecting telescope is the most ancient, and indeed continues to be the most common, even at this time, on account of the convenience attending its use, and therefore we will begin with an explanation of its theory. *Plate XXVII. fig. 1. Astronomical Instruments*, represents a section of this instrument as it was originally made, and *fig. 2.* is a representation agreeably to its improved modern construction; in both which we shall use the same letters of reference to the corresponding parts. A B C D, in each figure, denote the tube of wood or brass in which two concave specula are contained; the large one, B D, is perforated at the centre, and placed contiguous to the interior end of the tube, but in such a way as to have a little play when pressed by a circular spring behind it; E F is the small speculum, which is of shorter radius than the speculum B D, and has its centre placed exactly in the centre of the tube opposite the central aperture in the large speculum, and is so adjusted by the screws behind it, that the image of the large speculum forms a concentric circle on its reflecting surface, when viewed by an eye situated in the central hole of the large speculum. In this instrument, as in the refracting telescope, it will be most convenient to describe first the formation of the primary image of a distant object in the body of the tube, and then the microscopic means applied for rendering this image visible in an apparently magnified state; for in truth there is actually a *compound reflecting microscope* made use of as a constituent part of this instrument, in like manner as the terrestrial tube of a refracting telescope of the best achromatic construction, is in itself a compound *refracting microscope*. In the first place, agreeably to the laws of catoptrics, which we have explained, if we consider *ab* and *cd* two rays of light coming from the centre of a distant arrow in a state of divergence approaching to parallelism, and impinging on the

large speculum at the points *b* and *d* near the remote edges of the speculum, and at equal distances from its axis, they will be reflected inwardly so as to meet at the point *e*, in the common axis of both the specula, and will form the image of the central point of the arrow; and in like manner, any number of rays proceeding from the opposite ends of the said arrow may be conceived to fall on the speculum, and to be reflected to the points *b* and *i*, and to all the intermediate points, so as to form a perfect image *b e i* in an inverted position, because the rays which enter the tube from the right-hand end of the arrow, will after reflection cross the axis, and form the left-hand end of the image, and *vice versa*. When an image is thus formed, if it could be viewed, under sufficiently favourable circumstances, by an eye placed in the vertex or central aperture of the large speculum, it would subtend the same angle as the object itself seen from the same situation, as we have already demonstrated; and therefore the length of the image will bear the same proportion to the length of the object which it represents, as its distance from the eye, or vertex, is to that of the object; so that the longer the radius of the speculum which forms the image, the more distant, and consequently the longer will this image be, as compared with the object; and for the same reason, the nearer the object, the longer will its image be, until the situation is at the centre of concavity of the speculum, where the object and image will coincide, and appear of like magnitude, but in contrary positions.

This formation of the primary image being understood, we must in the next place consider it as a real microscopic object, placed somewhere between the face of the large speculum, and its centre of concavity, which situation will always depend on the distance of the real object itself, or, which is the same thing, on the degree of divergence of the incident rays coming from the object. Now if the small speculum were so placed as to have this primary image, or microscopic object, in its solar focal point, the rays coming from it would be reflected towards the large speculum in a parallel state; and passing through the central opening of the large speculum, would never converge so as to form a secondary image, in which case the conjugate focus would be said to be *infinite*: and if the said primary image were nearer to the small speculum than its solar focus, the reflected rays would diverge so as not to reach the central hole of the large speculum at all; but if the distance of the primary image *b e i* exceeds the solar focus of the small speculum E F, which is at the point *f*, then the reflected rays coming from the primary image will converge to a conjugate focus somewhere in the axis, and form a *secondary image*, the magnitude of which will increase with its distance from the primary image, which we now consider as a real microscopic object. The place where this secondary image will fall, will depend on the distance of the primary image from the solar focus of the small speculum; and a small change of this distance will cause a great corresponding change in the place of the secondary image, or conjugate focus; so that an adjustment for a small forward and backward motion of the small speculum, by means of a screw at the end of a long rod placed parallel to the tube, and reaching to the eye-end, will suffice for regulating the place where the secondary image shall most conveniently fall to be viewed by an eye-glass. The secondary image has its position reversed, as it regards the primary one, and is therefore in the same position as the object itself, or what is usually called *erect*, in opposition to *inverted*. This secondary image was originally made to fall within the tube, as at *k l*, in the focus of the eye-glass G H, through which it may be viewed by a small hole at I, where the visual angle

G I H

TELESCOPE.

G I H is now considerably enlarged. In order to explain the theory of this reflecting compound microscope, composed of the small speculum E F, and eye-glass G H, more particularly, which we purposely omitted to do under the term MICROSCOPE, let us suppose a ray of light proceeding from the end *b* of the microscopic object, or primary image *b e i*, and falling on the central part of the small speculum at *g*, it will return reflected from this point, so that the angle of reflection on the other side of the axis or line *g e*, will be equal to the angle of incidence on this side, and will therefore return in the line *g e l*, to the place of the conjugate focus, where the point *b* will be depicted at *l*: also a ray coming from the point *i* of the same primary image, and falling on the point *g*, will be reflected in a similar manner along the line *g b k*, and will form the point *i*, at *k*, in the secondary image, which we have represented by a dotted line. Now as the primary and secondary images are subtended by the same angle *b g i*, or *k g l*, at the vertex *g* of the small speculum, agreeably to the laws of catoptrics, it is evident that the linear magnitudes of these two images will be directly as their respective distances from *g*, the vertex of the small speculum; therefore, as often as the distance *g b* is contained in the distance *g k*, or the distance *g i* in the distance *g l*; so often will the length of the secondary image *k l*, exceed the length of the primary one *b i*. But this secondary image *k l* is viewed through the eye-glass G H, under the visual angle G I H, and is said to be again magnified thereby: let us next see what is the amount of this amplification; we have already said that an eye at the vertex *g* of the small speculum, would view both the primary and secondary images under the same visual angle *b g i* or *k g l*; but by an eye at I, the visual angle is G I H = *k K l*, because *l K* is parallel to *H I*, and *k K* to *G I*; and *k l* is the common subtense of both angles; consequently, as the distance *L K*, or focus of the eye-glass G H, is to the distance of *L g*, or distance of the small speculum from the secondary image; so is the apparent magnitude of the secondary image, or visual angle to the eye at *g*, to the same with the eye at I; and if the distance *g L* be that at which an object may be best seen by the naked eye, the whole

power of magnifying of such microscope will be $= \frac{g k}{g b} \times \frac{g L}{K L}$, provided that *b i* be considered as a real object under

microscopic observation. But in a telescope, the size of *b i* has a reference to the distance of the object which it represents, and this circumstance must be taken into consideration in estimating the power of the Gregorian telescope. When the eye is placed at *o*, the vertex of the large speculum, we have said, that the object and its primary image are seen under the same visual angle; therefore, wherever the primary image may fall in the line of the axis, the angle *b o i* will be to the angle G I H, or *k K l*, as the object seen by the naked eye is to its secondary image, as seen through the eye-glass, and consequently the latter, divided by the former, will give the power. But the visual angles *b o i* and *k K l*

are to each other in the compound ratio of $\frac{o e}{e g} \times \frac{L g}{L K}$,

which formula, expressed in measured distances, will be more convenient for ascertaining the whole power of a Gregorian telescope, than the ratio of the visual angles, which would require previous calculation. For instance, let *o e*, the distance of the primary image from the great speculum, be given = 24 inches; and *e g*, the distance of the same from the small speculum, be = 3.3; also let *L g*, the distance of the

secondary image from the small speculum, be = 25.5, and *L K*, the focus of the eye-glass, be = 2.3; then we shall have, agreeably to our formula, $\frac{24}{3.3} \times \frac{25.5}{2.3}$, or, which is the

same thing, $\frac{24 \times 25.5}{3.3 \times 2.3} = \frac{612}{7.59} = 80.6$ for the power of

such a telescope, when directed to an object at such a distance as shall make the primary image fall as we have taken it. For objects very near, the focus of the large speculum will be long, and consequently the primary image will approach the small speculum as the distance decreases; for which reason, the magnifying power will increase with the diminution of distance, and *vice versa*; so that the power with parallel rays, or when the telescope is used for celestial purposes, will be the smallest possible, and yet this is what is usually called the power of the telescope, which circumstance shews the impropriety of taking the power of a large telescope from a measure of a near terrestrial distance, which mode has been practised by eminent astronomers, and recommended by men of science. If, however, a correction is applied for the want of parallelism in the incident rays, as we shall have occasion to do presently, then the power may be as accurately obtained at a short as at a long distance. In the old construction, which our *fig. 1.* represents, the piece of bent brass at *c*, which supports the small speculum, is acted on by the long rod *l C*, that has a milled nut at *l*, and a screw cut on the end *C*, that draws the projecting part *N*, of the piece *c*, along a slit made in the tube, while a contrivance in the cock *M* prevents the rod *M N* from advancing or receding as the rod revolves. Hence the eye-glass G H remains fixed, and the adjustment for distinct vision is made by the rod *M N* moving the small speculum to its proper distance from the primary image *b i*; and in this way the secondary image may be made to rest in any given situation beyond or short of the point *L*, so that various eye-glasses may be used with the same specula in succession; or different small specula may be used with the same large one, from which changes a variety of powers may be had with fixed eye-glasses; but if the eye-glasses be inserted into a smaller sliding tube, there will be a third method of varying the power, by bringing the secondary image into the sliding tube out of the body of the large tube, so as to increase the distance *L g*, which is one of the factors of the dividend in our formula. Thus, whatever may be the arrangement of the specula, eye-glass, and distance of the primary image, when any three out of the four terms of the formula are given, together with the whole power, the fourth may always be had by a simple calculation, which is a matter of great convenience to the maker. If, for example, we take the power 80.6 = *P*, and the radius of curvature of the large speculum = 48 inches, in which case the primary image with parallel incident rays will fall at $\frac{48}{2} = 24$; and let *L g* and *e g* be respectively 25.5 and 3.3, to find the focus of the eye-glass that shall produce such power; we shall have $\frac{24 \times 25.5}{3.3 \times 80.6} = 2.3$ for the focus of the eye-glass; or for the distance *e g* of the primary image from the small speculum, when the eye-glass is given, we should have $\frac{24 \times 25.5}{2.3 \times 80.6} = 3.3$, as before. But it was soon found, that a single eye-glass not only produces fringes of colour near its edges, arising from the prismatic aberration of the rays coming from the secondary

TELESCOPE.

ary image, now considered as a real object, but that the field of view is thereby circumscribed into a small area. For these reasons, the Huygenian eye-piece, already explained, was substituted for the single eye-glass, which substitution left little more to be done, in the way of the improvement of the Gregorian telescope, except what related to the construction of the specula, which have now been brought nearly to a state of perfection, as we have explained, at some length, under our article SPECULUM. We have introduced *fig. 2.* for the purpose of explaining more clearly, than we could by a mere verbal description, the plan of the Gregorian telescope in its most improved state, in which, we repeat, the same letters indicate the same parts as in *fig. 1.* In this figure we have made the pencils of rays *ab* and *cd* to consist each of three lines, for the purpose of shewing how the image is formed at the points of convergence after reflection, and also how the inversion of the image is produced by the crossing of the pencils before they converge to a point at each end of the image. It may also be seen how the rays pass through the interior eye-glasses, before they form the secondary image between the two glasses, as in the achromatic astronomical telescope, thereby constituting this image a cata-dioptric one, which before was a catoptric one, according to our definition. The Huygenian eye-piece is peculiarly adapted for the Gregorian telescope; and when the specula have their curves so adapted as to counteract each other's aberrations, as we before recommended, and are also well polished, as well as of suitable metal, a very high power may be applied, and the light by reflection will be to that by refraction alone nearly as 5 : 8, where the apertures are equal; but as a reflector is capable of having a much greater aperture than any refractor that can be constructed, it will have a proportional advantage in the essential quality of illumination combined with power, on which union its excellence depends. It will not be necessary to repeat here what we have said above respecting the manner of determining a single eye-glass, equal in power to the combined eye-glasses in the Huygenian eye-tube; but it may be proper to mention here, that such a glass, when determined, must be substituted for the compound eye-piece, in computing the power of the telescope according to our preceding directions. The diaphragm that precludes the straggling and extraneous rays from coming to the eye is put where the secondary image is formed, and the aperture at the eye is obliged to be small in this construction of a telescope, to prevent any other light being admitted into the eye than what is reflected from the small speculum, and is necessary for the formation of the secondary image. When the diameter of the small speculum, and also the exact situation of the primary image, are known, the aperture at the eye, that shall admit the principal pencil, may be exactly determined by the subjoined analogy; *viz.* as the distance of the small mirror from the secondary image, is to the focal length of the nearest eye-glass; so is the diameter of the small speculum, to the necessary aperture at the eye. And to find the proper diameter of the small speculum, or central aperture of the large one, the proportion will be, as the distance of the primary image from the large speculum, is to its distance from the small one, with incident parallel rays; so is the diameter of the large speculum, to the diameter of the small one, or of its own central aperture; and when this proportion is preserved, all the reflected light will enter the small tube that contains the eye-glasses, and also the extraneous light not falling on the large speculum, if any, will be excluded. Lastly, should the field of view be required to be equal to a given visual angle, such as that subtended by the diameter of the sun, this will depend on the power of the instrument, which for this purpose must be

limited, as in the following example: let a reflecting Gregorian telescope of four inches diameter of the large speculum, and 17.5 inches focus, with a hole in the centre 1.1 diameter, (which is considered in practice a good proportion,) be required to have a field of view just 32', when the focus of the eye-glass is two inches? The thing required is, that the enlarged secondary image of the sun should just fill the aperture in the centre of the large speculum. The size of the primary image of the sun depends on the focal length of the large mirror, and must first be found: it has been ascertained that, in the focus of a speculum (or lens) of six inches focal length, the image of the sun is .05586 diameter, when he measures 32'; therefore, as it will be proportionably more in a longer focus, say as 6 : .05586 :: 17.5 : .1629; also, as often as this image .1629 is contained in 1.1, the diameter of the hole in the large speculum, which quotient is = 6.75; so much does the small speculum magnify the primary image, in converting it into a secondary one of 1.1 diameter. Again, if we divide the focus of the great speculum 17.5, by 6.75 - 1, we have 3.04, the distance of the primary image from the small speculum, which is somewhat more than its solar focus; and also if we divide 4, the diameter of the large speculum, by the same (6.75 - 1), we shall have .695 = the diameter of the sun's image on the face of the small metal, while the secondary image will just cover the hole of the large speculum, as required. Now, lastly, to find what is the power of the telescope under those limitations, we have $17.5 \times 6.75 = 118$ for the first part of the

power; then $\frac{118}{2} = 59$ = the whole power, when 2 is the

focus of the single eye-glasses. If the length of the focus of the principal speculum were increased to 30 inches, or even to 30 feet, while the aperture remains as before, no advantage would be gained in this construction from such length; for in the case of 30 inches focus, the primary image would be .2793, and the power of the small speculum only 3.93

$\left(\frac{1.1}{.2793}\right)$, while the distance of the primary image from the

small speculum would be 10.24; the diameter of the image on the face of the small speculum 1.36; and the magnifying

power $\frac{30 \times 3.93}{2} = 59$, as before. There would, indeed, be

this disadvantage, that, as the small speculum has an increased radius here, its diameter will necessarily be so much augmented, as to intercept several of the best rays of light, which are those that fall near the centre. The opinion, consequently, that a Gregorian telescope will be improved by having a long focus of the great speculum, with the same aperture, is erroneous. When two reflecting telescopes perform alike, as to light and distinctness, the square square roots of the diameters of the specula must be as the cubes of their foci respectively. There can always be more power got by the small speculum and eye-glass, in even a short tube, than the aperture will bear.

The theory of Cassegrain's telescope is very similar to that of the Gregorian, the principal difference being that, in Cassegrain's, the small speculum is convex instead of concave. When the radii of the two specula and the eye-piece are respectively the same in each construction, the powers will be the same, though the apparent position of the last image, which we have shewn to be erect in the Gregorian, is inverted in the Cassegrainian construction; for on examining *fig. 3.* which explains the course of the rays in Cassegrain's telescope, it will be seen that the incident rays *ab* and *cd*, after being reflected from the large speculum,

are

are prevented from coming to a point at the *virtual* image *hi*, behind the small speculum, in consequence of its interposition, but are again reflected towards the eye in a state of less rapid convergence, till, falling on the lens *GH*, they are refracted to a focus at *L*, and form the *real* image *Kl*, which may be considered as the primary image, and is, therefore, not in the same position as the secondary image, which is formed in the Gregorian telescope after the rays have *crossed* each other. When the rays fall on the large speculum, they are reflected in a state of convergence towards the small speculum, because coming from a distant object; and they enter the tube either parallel or diverging, accordingly as the object is more or less distant; but they fall on the small speculum converging, so as not to become quite parallel after the second reflection, but slowly converging; and the quantity of convergence will depend on the distance of the *virtual*, or what may be called imaginary focus, or image *hi*, from the small speculum *EF*, which is here between *f*, the solar focus, and the convex speculum; whereas in the Gregorian instrument, the solar focus *f* is between the concave speculum and image *hi*. In both

constructions, $\frac{og}{eg} \times \frac{Lg}{Lk}$ is the measure of the power;

and it is evident that the part $\frac{Lg}{Lk}$ is the same in both;

but it is not equally clear that $\frac{og}{eg}$ is the same, or in the

same ratio in both. The distance *og* between the two specula is less in Casségrain's instrument than in the Gregorian, by twice the solar focus of the small speculum, and by so much may the principal tube be shorter; therefore, it remains to be proved that *ge* is to *go* in one telescope as *ge* is to *go* in the other, though differently posited. In order to prove this analogy, let *HD* (*Plate XXVI. fig. 11.*) be a concave speculum, and *EC* a convex one, both described with the same radius *CD*, and on the common axis *BCD*; and let the point *N* intersect the radius, so as to become the solar focus of each speculum, one really, and the other virtually. Let *F* be a radiant point, from which the ray *FH* is incident on the concave mirror at the point *H*, or to which the ray *KE* incident on the convex speculum is tending: then both these rays will be reflected from their respective specula to the same point *B* in the axis, and will pass in the same line *EB*. Again, let *CF* be an object, and the image thereof *ab*, formed by the concave, will be equal to the image *AB* made by the convex. This may be proved from our preceding theorems for con-

vex and concave specula respectively, *viz.* $\frac{dr}{2d+r} = f$,

and $\frac{-dr}{2d-r}$, or $\frac{dr}{r-2d}$, when all the signs are changed.

For as *d* = *FC*, *CB* = *f* in the convex; so in the concave, let *FD* = δ , and *DB* = φ ; and then we have in the former *d* : *f* :: *2d* + *r* : *r*, and in the latter δ : φ :: *r* - *2* δ : *r*. But $\delta = d + r$, therefore *2* $\delta = 2d + 2r$, whence *r* - *2* $\delta = 2d + r$; consequently *d* : *f* :: δ : φ , that is, *CF* : *CB* :: *DF* : *DB*; also the object and image are to each other in the same ratio with each speculum; and, therefore, since the object is the same in both, the image will be the same also, or *AB* = *ab*, which was to be proved. After having given this demonstration, it will be unnecessary to shew how the powers may be varied at pleasure, agreeably to the variation of the radii of the specula and lenses that compose the eye-piece, all which we have just explained

with regard to the Gregorian arrangement. As the instrument which is the subject of our present consideration inverts the objects to which it is directed, it is seldom used but in astronomical observations, for which it is peculiarly adapted, seeing that it is capable of having greater power, with the same length of tube, than any other telescope that has been yet invented; though with a terrestrial eye-piece, it might be used for the examination of terrestrial objects. While we are writing our present article, we have before us a Casségrainian telescope by Tully, of 36 inches of tube, and $6\frac{1}{2}$ aperture, that will shew Saturn or Jupiter, with their moons very well defined, with a power of 440; and that will distinctly define the words of a page in this Cyclopædia, at the distance of 210 yards with a power of 295.

The maker of this instrument has constructed two pairs of telescopes, one of each pair a Gregorian, and the other a Casségrainian, so as to match each other exactly in dimensions, powers, and quality of the metals and glass, in order to ascertain if one construction has any advantage over the other in quantity of light, under exactly the same circumstances; and though several scientific gentlemen, besides the author of this article, have examined and compared different objects as seen successively by each of the two telescopes of both pairs, yet not the least difference can be discerned by any observer. When the last glimmering of day-light remained, the vanishing object ceased to be visible with each like telescope at the same time, as nearly as could be ascertained, and that with both pairs, though they are constructed with dimensions greatly different the one pair from the other, and vary consequently in their powers and quantity of light. This experiment originated out of captain Kater's paper on this subject, which was published in the Philosophical Transactions of London, in the year 1813; and we have no hesitation in saying that the quantity of illumination is the same in both constructions, when the dimensions and qualities of the constituent parts are perfectly similar. Whatever may be the dispersion of light at the point of crossing of the rays, in the Gregorian construction, when the dispersed rays are returned from the second speculum, they are collected again, it should seem, *without loss*, certainly without apparent diminution of light. This conviction we put on record, not out of a spirit of controversy, but from a love of truth.

The first account that was published of the French reflecting telescope was in the fifth volume of the Philosophical Transactions of London, in the month of May, in the year 1672, almost immediately after the account of sir Isaac Newton's construction, which was given in the same volume; and a claim was set up by Casségrain as to the priority of his contrivance, which, however, was not substantiated; nor was the matter of importance to determine, as the constructions are dissimilar, and as Dr. Gregory's instrument preceded both. The supposed advantages of Casségrain's telescope over Newton's were stated to be these: *viz.* 1st. That the aperture was not limited to a confined number of rays incident on the large concave speculum; 2dly. That the reflection of the rays will be natural, since it is made upon the axis itself, and will therefore be more vivid; 3dly. That the vision will be more pleasing, when the face is screened from too much light by the broad end of the tube; and, 4thly. That there will be less difficulty in discovering objects with the eye facing them, than when turned from them. If these are advantages, they are, however, equally belonging to the Gregorian telescope; and we shall presently have occasion to state what was Newton's opinion on each of these points. In this, as in the Gregorian construction, the power can always be increased farther than the aperture will bear; and,

TELESCOPE.

and, therefore, an increase of focal distance of the large speculum, without a proportional increase of aperture, will answer no good purpose, but will render the tube unmanageable. When the aperture of a Cassegrainian or of a Gregorian telescope is to that of a Newtonian as 7.5 to 6, it has been proved that they have equal light with the same powers; the Newtonian having the advantage, in consequence of the obliquity of the angle of reflection of the small plain speculum.

Sir Isaac Newton's construction of the reflecting telescope differs from both the Scotch and French in this respect, that the large concave speculum is entire, and that the small one is quite plain, and placed at an angle of 45° , a little short of the focus; so that the converging rays come to a focus between the small speculum and the side of the tube near its superior end, as seen in *fig. 4.* of our last plate. Sir Isaac had discovered, in his experiments on reflected light, that more rays are reflected in an oblique than in a perpendicular direction; and that, consequently, there would be more light returned to the eye by a small speculum set at 45° , than would be if the angle of reflection were greater. In this instrument, the theory is much more simple than in either of the preceding instruments, on account of there being but one image, *h i*, formed by the incident rays *a b* and *c d*, after two reflections, one of which takes place at the large metal *B D*, and the other when the rays are in a state of convergence, at the small plain speculum *E F*; so that the whole length of the focal distance of the large metal *B D*, is $B F + F e$, or $D E + E e$; and this distance, divided by the focal distance of the small eye-glass *G H*, reaching to *e*, gives the whole power. This calculation is as simple as in the astronomical refracting telescope above explained; and is analogous thereto. In the instrument first completed by Sir Isaac, the eye-glass was a plano-convex, with the plain face turned to the eye, and $\frac{1}{8}$ th of an inch focus, while the focal distance of the large speculum was $6\frac{1}{2}$ inches, and its aperture $1\frac{1}{2}$; hence its magnifying power was $\frac{6.33}{.166}$, or

$\frac{6\frac{1}{2}}{\frac{1}{8}} = 38$. This was at the time considered a good proportion between the power and aperture, and a table was constructed for different focal distances upon this radical proportion; but it would answer no purpose to copy this table at a time when the reflecting telescope, in every construction, is brought to nearly a state of perfection by the successive improvements of different artists. In this way of producing the image, the position is inverted; and the only mode of increasing the power with the same eye-glass, is by lengthening the tube and focus of the large speculum; or with the same large metal, by shortening the focus of the eye-glass. In this telescope, any of the eye-pieces, simple or compound, may be applied at pleasure: and if the large speculum be made of the best metal, of a proper parabolic figure, and with a good polish, the image will be sharp and well defined; and as there are no colorific rays in a separated state, the charge, or power of the eye-piece may be great in proportion to the focal length of the large metal, which is the distinguishing character of this construction, particularly when the small speculum is perfectly flat and well polished. The principal objection to this, as a portable instrument, is its unmanageable length, which was first given it by Hadley, who out of a pigmy made it a giant, and astonished the philosophic world. The length of the tube was made six feet, in which was included a metal of six inches aperture, and $62\frac{1}{2}$ focus; and Newton's power of 38 was

increased to 230. See *Phil. Trans.* vol. xxxii. p. 303, or *Abr.* vi. p. 165.

In Sir Isaac Newton's reply to Cassegrain's claim of superior advantages, he states, first, that there will be more light lost by reflection from a small convex speculum, than from a plain speculum of an oval shape, and placed in an oblique position; secondly, that the convex speculum will not reflect the rays so truly as the plain one, unless it be of an hyperbolic figure, which is difficult to form, and even then will reflect only those rays truly which respect the axis; thirdly, that the errors of the convex surface will be augmented by the distance through which they pass before they reach the eye; fourthly, that the errors of the convex surface will be increased by the deflection or bending of the figure from the points where the incident rays ought to fall; fifthly, that on this account the figure is required to be more perfect than art can make it; sixthly, that the errors of the large metal, which is considered to be spherical, will be so augmented by reflection from the small convex metal, that indistinctness will ensue, such as will not allow either a great aperture, or a high charge; and lastly, that as the small metal contributes to increase the power, an over-charge of power, compared with the aperture and focal length of the large speculum, will be unavoidable, so as to produce very obscure and confused vision; for if the small metal be made with a larger radius, in order to diminish the power, too many of the incident rays will be intercepted; and if the charge of the eye-glass is diminished, the area of the field of view will be so far diminished, as to render a small object only visible, and that difficult to find. These might be objections a century and a half ago; but most of them have yielded to subsequent improvements in the nice art of casting, grinding, and polishing of specula, which we explained under the word *SPECULUM*, and in the formation and arrangement of the Huygenian eye-piece, which we have said is peculiarly suited to reflecting telescopes; though single lenses will do very well when the spectator confines the axis of his eye to coincide with the axis of the lens, so as not to produce distortion in the figure of the image viewed. It may be proper to mention further here, that the small telescope called the *finder*, attached to telescopes of considerable power, was first proposed by Sir Isaac Newton, to remedy the difficulty of finding the object with his reflecting telescope; and Descartes hath described it in his "*Dioptrics*" as answering the same purpose when applied to his best telescopes. Indeed objections well founded and rationally stated have led to various improvements in the mechanical arts, and are never to be disregarded, unless they are obviously futile. Had Sir Isaac Newton lived to have a peep at the instrument which next claims our attention, he would no doubt have been highly gratified at the progress which the art of constructing telescopes has made since his six-inch reflector, with its ball and socket, was mounted over a candle-stick, or a small pillar greatly resembling this domestic utensil! And yet, to do justice to his inventive genius, if we may apply figurative language to such a subject, the seeds of all the fruit that has since been matured were contained in his primitive little kernel; and we are proud to claim the Newtonian as the *English* production.

"Though last not least," the Herschelian telescope now offers itself to our consideration, which we might with some propriety call the German telescope, inasmuch as the celebrated contriver of its stupendous mechanism is a native of Hanover: it was however constructed in England, and by English workmen, except so far as the ingenious knight of the Royal Hanoverian Guelphic order lent his

TELESCOPE.

powerful assistance, partly in the execution, but chiefly in the contrivance of the mechanical appendages. The work was immense, but royal means furnished the power that overcame every obstacle. In magnitude, as in power, the forty-foot reflector at Slough exceeds every instrument that human industry has yet put together, and stands as a proof of great mechanical skill directed by an enterprising mind. We trust that we cannot be understood to derogate from the merit of Dr. (now sir William) Herschel, when we state that the idea of giving a small degree of obliquity to the large speculum of a reflecting telescope, so as to bring the image formed in the focal point out of the body of the tube, at its aperture, originated with Le Maire (see *Machines Approuvées, par l'Acad. vi. p. 61.*) about the year 1728; for as we know not that this suggestion ever met the eye of this illustrious astronomer and mechanic, previously to his undertaking the Herculean labour of constructing a telescope with a speculum of forty feet focal distance, and four feet diameter, it would be unfair not to allow him the credit of the invention as well as of the construction. We mention the name of Maire in compliance with our system of tracing, or attempting to trace, from historical evidence, the origin of each mechanical invention that has contributed, immediately or remotely, to the promotion of the mechanic arts. The theory of this construction is easily explicable, by a reference to *fig. 5.* of our plate of the *Theory of Reflecting Telescopes*, in which, as before, A B C D is the tube, and B D the large speculum of the immense weight of 2118 lbs.; the incident rays *a b* and *c d*, which would have come back to a focus at the point *c*, in the centre of the aperture, if the axis of the speculum had coincided with the axis of the tube; in consequence of a small inclination of the speculum, given by screws behind, come to a focus near A, at the edge of the tube, where the image of the object is formed by only *one reflection*, which is the leading feature of the construction. This simplicity of principle is very convenient when a large aperture is wanted, because the head of the observer may be placed entirely at one edge of the tube, so as not to intercept any of the rays at the time of making an observation; but as the eye looks down the tube in every state of elevation, not only must the back be turned to the object viewed, but the observer must be mounted nearly as high as the superior end of the tube, in order to make his observations: hence various pulleys, ladders, scaffolds, &c. became necessary to enable the observer to adjust both the instrument, and at the same time his own position, all which will be best understood from the drawing, when we come to explain the particulars of the construction hereafter. The power of the Herschelian, as that of the Newtonian telescope, is obtained from the ratio between the focus of the speculum and the focus of the eye-glass, which in this instrument is not very short, though the image is formed by simple reflection. The mode of varying the power is the same, therefore, as in the Newtonian reflector, and requires no further explanation.

4. *The Construction of Telescopes.*—As we have now given both the *history* and *theory* of telescopes at considerable length, we shall not be under the necessity of dwelling long on each of the several constructions; particularly as a reference to the drawings which we have given, and which are mostly original, will exhibit to the eye more precise information on this part of our article, than any the minutest detail would do, unaccompanied by such visible representations. Now that the long *aerial* telescopes are no longer in use, we shall not fill our pages by describing the different kinds of mechanism that were applied for rendering them useful in observations,

by Huygens, Perrault, Sebastian, Mairan, and others; most of which are described in vols. i. v. and vi. of the "*Machines Approuvées par l'Académie, &c.*" to which we beg leave to refer the curious reader who wishes to know the particulars. All the supports for long telescopes had necessarily one property, which is desirable also in stands that are made for modern telescopes, but which is frequently neglected; and that is, that the object-end of the telescope was steadily supported by some point of rest near the remote extremity, where the rays were incident. Indeed various stands or mountings, as they are sometimes called, have been contrived for the convenient support of a telescope, when it is too heavy for the pocket, and incapable of sliding by concentric tubes into a portable form; but in every useful stand the following properties ought to combine: first, the instrument held by it should be kept firmly in its place, if of the refracting sort, so that the image may have no vibratory motion unfavourable to distinct vision, occasioned by an unsteady position of the object-glass; but if it be of the reflecting kind, then it should be so suspended, that tremulous motions arising from compactness of the materials, such as easily transmit vibratory impulses, may be avoided: secondly, a motion in azimuth, and another in altitude, are indispensable; and if the instrument be bulky, or have great power, in each of these respects there should be both a quick and a slow motion, the former to save time, and the latter for the sake of accuracy: thirdly, when the instrument is pointed to the required object, it should not be liable to be easily moved by any accidental touch of the observer's hand or body; unless it is managed in a state of suspension, as is the case with the larger reflectors: fourthly, the parts of the stand should be strong enough to bear the superincumbent weight, and not liable to get out of repair; and fifthly, its position should be in a situation not easily shaken, or moved by the observer's weight, or that of a bystander. When these properties are attended to, the exact shape and external appearance become matters of secondary consideration, and each artist may pursue his own schemes in the construction; but in this, as in several other departments of the mechanical arts, that work is best and quickest performed, which is done from approved patterns.

Refracting.—We will first describe the refracting telescopes represented in *Plate XXIX.*, and shall then proceed to the reflecting instruments contained in *Plates XXX.* and *XXXI.* of *Astronomical Instruments*, omitting those portable instruments that are in the hands of every reader, such as opera-glasses, &c. and that belong more properly to the head of *OPTICS.*

One of the best stands for a thirty-inch refractor, by which we always mean an *achromatic* refractor, is that exhibited in *Plate XXIX. fig. 1.*; in which A B is a tube of brass, mounted on the tripod stand of the same metal C D, and fixed by means of the screws Q and R. In the common construction, the horizontal motion is at C, at the top of the stem or cylinder, and the system of tubes F, E, P, is not applied, so that there is neither the slow adjustable motions, nor is the instrument steady in any given position; but here the horizontal motion is at D, at the lower extremity of the cylinder, where there is a long bearing for the pivot, with a tightening screw underneath the junction of the feet, and a clamp S to fix the instrument in any given direction. Also the handle in *fig. 5.* with a Hooke's joint, taking the squared axis of the screw at D, gives the slow motion in azimuth, while the sliding and adjustable tubes F, E, P, keep the angle of elevation unaltered. These tubes turn on a joint at P; and when a due elevation is given by the quick motion, occasioned

TELESCOPE.

fioned by the freedom of sliding, one within another, a clamping screw at E fixes them, and the slow motion produced by the screw F, finishes the observation in altitude, as the handle in *fig. 5.* does in azimuth; and both slow motions can be managed, one with each hand, at the same time. In the present representation, the celestial eye-piece H is screwed into its small tube, which bears a concealed rack, that is acted on by a pinion on the axis of the thumb-piece G, which may be made more or less tight by a screw in the middle of its plane, and which adjusts the eye-pieces for distinct vision. There may be any number of various celestial eye-pieces, but two or three are as many as are usually delivered with an instrument of this size. The object-glass screws into the mouth of the tube at B, and is so fixed by trial, that the most distinct view of an object is had when the screw is carried home, in which situation the receiving socket is fixed by the maker; so that unscrewing the object-glass at any time does not injure the instrument. The centre of motion in altitude is at a joint above C, and the steadiness of the tube A B will depend on the distance of this joint from the system of concentric tubes F, E, P, which may be more conveniently placed towards the eye-end than towards the object-end of the main tube, and with equal effect. When the cylindrical piece beyond the joint of the lowest tube at P, is withdrawn from its hole in a cock, attached to the vertical cylinder, the tubes will pack into one another, and the cylindrical end-piece will enter the hole of the cock T, under the main tube, and remain out of the way of injury, parallel to this tube. The tube I K, in *fig. 2.* screws at the end I, into the same place that the celestial eye-piece H now occupies, and is called the terrestrial tube, or terrestrial eye-piece, because objects are seen in their direct position through it, which through the celestial eye-piece are seen inverted. Near the end I, a pair of glasses, called the *field-glasses*, are screwed, and the end K contains the pair of glasses which is denominated the eye-piece. We have already shewn that these two pairs of glasses constitute an achromatic eye-piece, at the same time that they erect the inverted image formed by the object-glass in the small tube between H and A; and when this image is considered as a real object, then the terrestrial tube is a compound microscope of the best construction. This mode of describing the arrangement of glasses, it is presumed, will be more easily understood by those readers who understand the construction of a compound microscope, than any other explanation that can be given. The tube L, in *fig. 3.* is an open tube, which is sometimes made, by particular desire, to receive at its end L the eye-piece, now screwed into the tube I K at K; and then, as the empty tube L slides in the tube I K, the distance between the pair of field-glasses and pair of eye-glasses may be varied at pleasure; and as the magnifying power of the compound microscope varies directly with this distance, it is evident that the power of the telescope thus constructed will vary in like manner. But we have shewn above, that the power of the telescope may be varied also by varying either the pair of field-glasses, or the pair of eye-glasses; hence, when a great variety of powers is desired for the same instrument, different pairs of field and of eye-glasses may be adapted to the same terrestrial tube with very little additional expence; and in *fig. 4.* we have given three different pieces of short tube, containing male or female screws, or both, which are called *adapters*, by means of which the celestial eye-pieces may be adapted as eye-pieces to the terrestrial tube, so as to gain a great increase of power for particular purposes. When the adapter M, in *fig. 4.* which has both a male and female screw, is screwed into the end K, of the terrestrial tube in *fig. 2.* the celestial piece H, *fig. 1.* may be substituted for the pair of

eye-glasses belonging to this long tube, whenever occasion may require; or the pair of terrestrial eye-glasses may be made a celestial pair, on occasions when a low power and enlarged field are wanted. The adapter O, in *fig. 4.* has two dissimilar female screws, the smaller one of which screws upon the long tube at the end I, while the larger end receives the outer end of the celestial eye-piece H, in *fig. 1.* and converts it into a pair of field-glasses, for which it may be substituted, to get the greatest possible power, with a high magnifier also at the end K, or rather at L, with the sliding eye-tube; and in this way the power may be increased so much, that all light will disappear, and the instrument, consequently, will then become useless: but it is better to have additional pairs of proper field-glasses, than to substitute eye-glasses for this purpose, because the arrangement of the focal distances of the field-glasses is different from that of the eye-glasses, when they are arranged in the best manner, as we have explained under our last section. The adapter N has two male screws and a female screw, one of which male screws will fit the tube at H, *fig. 1.* and the other the tube at K, *fig. 2.* or L, *fig. 3.* and the female screw will receive Troughton's micrometer in either place, or any eye-piece having a mother-of-pearl micrometer, even though it may belong to another telescope. Thus the adapters, which are simple in their construction, of little expence, and very portable, afford a variety in the use of a telescope, that is at the same time both useful and entertaining; and we have been the more minute in our description of them, because they have never before been brought into public notice. The powers of this telescope usually vary from 25 to 100 without the adapters, as they are made by opticians; and opticians are no advocates for adapters that increase the powers too much; but for certain purposes the power may be augmented to about 120 with distinctness and tolerable light; but then it must be recollected, that the field of view will admit of only a small object, as well as little light, when the power is augmented out of due proportion.

Fig. 6. is a representation of a five-feet achromatic refractor, mounted in the most useful and convenient manner for making either celestial or terrestrial observations, and has all the appendages which we have just described as belonging to the thirty-inch refractor, when made in the best manner. A B, as before, denote the main tube, which has a diameter of $4\frac{1}{2}$ inches; and instead of one set of sliding concentric tubes, here are two, inserted into the cocks P and P, of a three-legged stand of mahogany, of which two legs only are seen in the figure, and these shortened, so as to fall within the room allotted them in the plate. The construction of this stand has been described under the article *EQUATORIAL Stand*, with a reference to *fig. 5. Plate XIII.* of our present series of plates; therefore we shall satisfy ourselves with such a short description of the constituent parts here, as will simply enable the reader to understand their uses. The milled nuts Q and R, attach the main tube A B to the wooden stand; and the tubes A P and A P keep it steady from vibratory motion: the semi-circle of brass between Q and R, moveable about its centre, is racked at the concave part of its circumference, so as to fit the screw on the axis of the handle U, which we have made short, to avoid confusion in the figure; therefore, when the screw is pressed close into the notches of the rack-work, a revolution of the handle U, in either direction, will produce a corresponding motion, in elevation or depression, in the telescope borne by this semi-circle, while the vernier and divisions on the face of the semi-circle indicate the quantity of elevation, when zero is properly adjusted. The manner in which this mechanism acts, and also the method of

producing horizontal motion, will be best understood from an examination of *fig. 7*, in which the parts are enlarged, and in which the same letters denote the same things. The thumb-screw *V*, concealed in *fig. 6*, when turned round, presses on the fixed metal under it, and draws up the frame *Y*, of which one fidé is seen, that holds the axis of the screw *U*, and that turns on two pivots at its remote end *X*; and in this manner the screw is brought into contact with the notches of the racked semi-circle, or is detached from it by a contrary motion. In the former case there is a slow motion in altitude, and in the latter a quick one. Again, the axis *S*, of another horizontal and parallel screw, receives the handle, like *fig. 5*, for giving the motion in azimuth. This screw is also pressed into contact with a horizontal racked wheel, that lies fixed between *S* and *W*, and gives the slow motion. The screw of pressure is seen above *S*, and when the axis of the handle has its screw detached from the racked circle, the telescope is at liberty to have a quick motion in azimuth. The chamfered plate, on which the racked circle rests, is graduated, and the vernier at *W* reads the hours and minutes of time: but in order that this circle may be parallel to the equator in the heavens, so as to indicate time truly, it is necessary to turn the upper half, *C*, of the block half round, and to turn the whole stand so that the plane of the graduated circle may be parallel to the plane of the equator, which it will be when the upper point of the axis of motion is directed exactly to the north pole, in which situation the hour-circles will coincide with the horary circles of the heavens, or must be made so by an adjustment, which the graduated circle is capable of receiving, by means of an elongated hole, into which the screw enters that fixes it to the block. This block, we have said before, is called Smeaton's block, and answers the purpose of giving an equatorial motion to the telescope, when following a heavenly body by night, and is useful for finding one by day, from a knowledge of its right ascension and declination; for what was altitude in the horizontal position, becomes declination in the equatorial elevation. This telescope is one of the four of which we propose to exemplify the uses in conjunction with Troughton's micrometer; and therefore we have had the micrometer put into its place at *K*, when the terrestrial tube *I K* is used; but it might have been at *H* in place of the celestial eye-piece, where the value of the revolutions of the micrometer screw would have been as we have tabulated it in our last section. The two terrestrial eye-pieces in *fig. 8*, and one not given there, are made to screw into the terrestrial tube at *K*, in addition to all the four celestial eye-pieces, which have an adapter to fit them to the same place successively; which variety affords the choice of seven terrestrial powers with one pair of field-glasses; and as there are three pairs of field-glasses, the variety becomes $3 \times 7 = 21$ different powers with a fixed eye-tube; but as the eye-tube also slides, the powers may be varied in small quantities at pleasure between the two extremes. In this instrument, the end *I* of the terrestrial tube does not screw into the celestial tube that bears the rack, but into an intermediate sliding-tube, which is here marked *H*, the use of which is to allow an adjustment for vision at very short distances, which adjustment requires a great length of tube to be drawn out. For the construction of Troughton's and other micrometers, we must refer to our article MICROMETER.

The screw *G* of adjustment for distinct vision, is concealed in our drawing by the finder or small telescope attached, over *A*, to the main tube, the use of which is to bring the object readily into the field of view of the large telescope; which is not an easy matter, when the power is great; for

as the field of view increases with a diminution of the power of the telescope, and *vice versa*, the small telescope saves much time in searching for any object that is visible in it. But the micrometer would be of little use in the night for measuring small angles, except when the moon is the object, unless some mode of illuminating the wires, or spider's lines, used in making the measurement could be adopted. Formerly this object was effected by a piece of brass, faced with card paper, attached to the object-end of the telescope, as in *fig. 15*, and turning on a pivot, *A*, to any angle of inclination or reclination that the position of a lamp, or candle, might require, of which the light was to be reflected into the tube; and an oval hole, in the middle of the reflecting plate, admitted the incident rays coming from the object to be viewed: this plan, however, is attended by the inconvenience, that either the lamp must be suspended by the object-end of the telescope, so as to rise and fall with it, or otherwise the angle of inclination or reclination of the reflecting piece must be altered in every new position. The first person who, we believe, laid aside this apparatus, and introduced a diagonal reflector into the body of the tube, was the Rev. Dr. Usher of Dublin, who brought the light within the axis of motion of his transit telescope, as is now commonly done; which method has the advantage of giving light in the same manner at all elevations, while the place, where the lamp is placed, never varies. (See the Transactions of the Royal Irish Academy, 1788, vol. ii. p. 13.) This method, however, was not considered as applicable to an ordinary telescope, where the axis of motion is below the tube; but Mr. Troughton has very lately applied this principle with success in the telescope before us, and in others of the same construction. At *Z*, over the centre of motion, a hole is made in the tube, of about one half the diameter of the tube, into which a covering cap of brass screws, when extraneous light is not wanted; then an elliptical plate of brass, rough gilt, with an elliptical hole in the middle, is reclined in an angle of 45° , within the main tube, in such a way as to receive the lateral light of a lamp or candle, which it reflects along the tube to the eye-piece of the micrometer; and the light thus reflected is not only mild and pleasant to the eye, but may be modified, as to quantity, by the position of the lamp, and will remain the same in all altitudes, if the lamp be in the same horizontal line with the reflector, and stand at a proper angle with the plane of the reflector. In using the telescope before us, we found that some of the rays falling on the extreme parts of the object-glass were lost in the tube, and that consequently either the diaphragm was too small, or that the oval aperture of the inclined reflector was not sufficiently large; but the distinctness of the image is no doubt promoted by such exclusion: and, indeed, it is the practice of some opticians, when they find the longitudinal aberration arising from the spherical figure of the convex glass not well compensated by the concave one, to shut out the extreme rays on purpose, by the use of a small diaphragm, for which assertion we have Mr. Dollond's authority. In the instance before us, we have ascertained by a dynameter, that the reduction of the aperture is in the ratio 30 : 25.6, namely, from 4.5 to 3.84 inches: but our intention is to have the original aperture restored.

When a refracting telescope exceeds five or six feet in length, it requires to be supported at both ends, and then the nearer support must have adjustments for both altitude and azimuth, while the remote one may be a point of rest. *Fig. 8. Plate XXX.* shews a support for the eye-end of a long telescope, which we believe was contrived by Smeaton, and which answers its purpose sufficiently; *A B C D* is a mahogany

TELESCOPE.

mahogany light frame, four feet six inches high; the cross-piece, A B, is fifteen inches long, and the piece C D seventeen, at the distance of eighteen from the other; another frame, E F G H, with parallel sides, nine inches apart, and more slender than the other frame, passes through the cross-bars of the former, in such way, as to have an easy motion; a cylinder or rod of brass is screwed by its head-piece to the cross-bar E F, and descends from M to N, through a wooden screw L O, which is hollow within, and cut into a screw round its circumference: this wooden screw terminates above with a brass socket and thumb-screw, which acts as a screw of pressure against the interior brass rod: the thick wooden piece L has a female screw, acting with the male screw of the hollow wooden cylinder L O, but is so made fast to the cross-bar A B, by a circular plate of brass above, that though it will turn round, it will neither ascend nor descend; consequently will produce an ascending or descending motion in the wooden cylindrical piece L O, and also in the brass rod M N, held by the screw K, attached to it. The concave piece of brass I has two motions in its stem, one horizontal, and the other vertical, like those in the stem of a small telescope, and receives the eye-end of a long telescope, to which it is screwed, while the remote end is supported by the branch of a tree, the block of a pulley, an opening in the roof of a house, or other elevated part of a building. The adjustments are thus managed; when the elevated end of the telescope is made to rest on its bearer, the eye-end adapts itself to the inclination by the joint in its stem under I; then the whole frame is turned to face the object, when the circular motion of the same small stem yields, and allows the long tube to remain quiet; and if the tube is not exactly pointed in azimuth to the object, the brass piece P, into which the stem I is made fast, slides along a groove made in the front face of the cross-bar E F, until the adjustment for azimuth is complete. This sliding motion, being manual, may be either quick or slow, as the observer desires; therefore, when a body in motion is once in the field of view, it may be followed without difficulty, by pushing the sliding-piece P in a proper direction. The quick and slow motions for adjustment in altitude are separate, and are thus produced; first the thumb-screw K is turned back, so as to let the rod M N ascend freely, till the altitude is nearly right, when it is fixed, and then the piece L is turned, backward or forward, as the case may require, with the right hand, while the left slowly slides the piece P, until the object is in the middle of the field; and when distinct vision has been properly obtained by the small tube at the eye-piece of the telescope, the pieces L and P, held respectively in each hand, will always afford the means of keeping the object in the proper part of the field; and though the support has but two legs, yet its connection with the support at the object-end, through the heavy tube of the telescope, will always keep it in its place when the adjustments are settled. It will not be necessary to describe any more stands, of which a great variety might be produced, that have been devised for refracting telescopes, because we presume that our readers will be able, after what we have said on this subject, to select such as may best suit their respective purposes.

We come now to describe the portable patent achromatic telescope, without a stand, that was invented by Dr. Brewster, and is sold under the patent by Mr. Harris, optician, in Holborn, London. The construction of this telescope, of which we have already explained the theory, is two-fold, and may be explained by *figs. 4. and 5. Plate XXX.* In *fig. 4.* the tubes are supposed to be transparent, or otherwise so divided, that the interior parts may be seen in their respective situations; A B C D is the outermost tube, of ma-

hogany, with brass ends, containing an achromatic object-glass, A B, at its exterior end; E F G H is the next tube of brass, sliding smoothly into the mahogany one, without lateral shake, and may be called the second tube: into this tube the third tube I K screws; and in its turn receives the fourth, or terrestrial eye-tube L O, containing the pair of field-glasses L M, and pair of eye-glasses N O; all which tubes slide into the space of twelve inches, (including the cap,) to fit the pocket. The principal object-glass, A B, is an inch and seven-eighths in diameter, and has a solar focus of 18.5 inches; and if there were no other glasses but the four contained in the terrestrial, or fourth tube, this would be nothing more than an ordinary portable or pocket achromatic telescope: but at I, in the second tube, is screwed a second object-glass of the achromatic sort, the diameter of which is one inch and three-eighths, and its solar focus 14 inches. When the second tube, E F G H, is pushed into the wooden tube A B C D, the second object-glass, I, approaches the principal object-glass A B; and when the third tube, I K, is also pushed in, the two object-glasses come nearly in contact at the end A B of the telescope: in this situation, the compound focus of the two object-glasses, by

the theorem $\frac{F \times f}{F + f}$ is about eight inches, which is the

shortest possible; and in this state of the tubes, when the eye-glasses are adjusted for distinct vision, the power is the smallest possible; but when all the tubes are drawn out, the distance between the object-glasses, and consequently the power, will be the greatest possible, because the converging rays coming from the principal object-glass A B, will have passed through one half of the tubes before they fall on the second object-glass, and undergo a second refraction, so as to come to a shortened focus. In every intermediate position of the object-glass I, the power of the telescope, that is, the compound focus of the two object-glasses, will be determined according to their intermediate distance, by the

theorem $\frac{F \times f}{F + f - d}$. Thus in every new position of the

second object-glass I, the telescope will have a new power, and these powers might be marked by a scale running lengthwise along the second and third tubes which separate the two object-glasses; but the inventor has made another use of this property, by converting it into an *optical micrometer*: he has fixed two parallel wires in the focus of the eye-piece, and also two points of metal, to include a larger angle, in a direction at right angles to the former; so that when one pair includes a horizontal angle, the other will include a vertical one; an experiment is then made by actual measurement, of a divided scale, placed at a measured distance, to ascertain what is the angle measured by the points in the eye-piece, when the object is seen between the parallel wires in each of the extreme positions of the second object-glass I, and strokes are marked accordingly, as the boundaries of the intended scale, the end of the next contiguous tube being the index; thus in the instrument before us, the extreme points or strokes of the scale *a b*, in *fig. 5.* measure 110' and 218' respectively, at an interval of 15½ inches; and as it has been determined, both from theory and practice, (see Dr. Brewster's *Treatise on New Philosophical Instruments*,) that the scale of measures is a scale of equal parts, these 15½ inches are divided into 108 (218.—110) minute spaces, while each minute space is bisected into spaces of 30", which might again be bisected by the eye, if the adjustment for vision could be made so nicely as to admit of such estimation. Hence it is easy to conceive how this telescope will measure any angle subtended by a distant object of unknown dimensions,

sions, between 110' and 218', within the accuracy of 30": it is also easy to conceive, that, the angle increasing as we approach an object, the same object may be made to fill the field between the measuring points in a new station, provided the distance between the two object-glasses be so altered, by trial and adjustments, that the exact power is found such as will command this condition, and the new angle at the second station will be indicated, as the old one was at the first; and when the distance between the stations is measured in a right line leading directly to or from the object, the difference of the angles will afford data for determining the distance of the object from either station. For example, supposing the tangents of small angles to be equal to the angles themselves, which they are very nearly, let us call the greater angle m , the smaller angle n , and the distance between the stations a ; then, as the distances of the object from each station will always be inversely as the measured angles, we have $n : m$ (of the angles) for the ratio of the distances, and the real difference of the same distances by measurement of the interval; therefore, by one of the simplest

theorems in algebra, we have $\frac{a m}{m - n}$ = the greater distance,

and $\frac{a n}{m - n}$ = the smaller distance: thus, if we suppose the

first, or smaller angle = 46', and the second, or nearer = 68',

with the interval 120 feet, we shall have $\frac{120 \times 68'}{68' - 46'} =$

$\frac{8160}{22} = 370.9$ for the greater distance, $\frac{120 \times 46'}{68' - 48'} = \frac{5520}{22}$

= 250.9 for the smaller, and the difference, as before, 120.

But it will be seen in a subsequent section of our article, that to determine distances from small angles with great accuracy, the value of a single second ought not to be neglected; and that a correction for want of parallelism, at short distances, is necessary for obtaining the true angle, whenever that is wanted. The author, however, has shewn, that the correction in question will vary nearly with the varying length of the telescope, and will not affect the ratio of the angles measured, on which the respective distances depend; but this coincidence of the correction with the length or power of the telescope, does not obviate our objections where real measures of angles are required, and where extreme accuracy is necessary for the success of the operation. But we have said the construction is twofold: it is extremely difficult, if at all possible, to hold the telescope so steady without a stand, that the angle, contained between the two fixed points in the focus of the piece, can be measured with precision; and this difficulty probably led to the substitution of the divided object-glasses, seen in fig. 6, and edgewise in fig. 7, for the second object-glass I, which we have described. If this divided object-glass, screwed into the second tube at I, had precisely the focal distance as the entire one, and had the centres of the semi-lenses brought exactly into contact, the same scale and the same mode of taking the measure of an angle, would apply with it as with the one we before denominated I; likewise the points in the eye-piece would be necessary. But to do away the use of such points, and to render the instrument equally useful without as with a stand, the second object-glass that we have now to describe, as constituting the second construction of the telescope, was divided in the centre diametrically, and had its centres removed from each other, so that each semi-lens forms a separate image of the object viewed. In this construction, two points may be fixed on in any object, and when the tubes are so drawn out, that point a in one image coincides with point b in the other,

as in Dollond's object-glass micrometer, then the angle subtended by a line connecting the points a and b will be indicated on the second scale, or scale cd , in fig. 5. This scale in our instrument begins with 11', and ends with 75'; so that the length of 15½ inches, being divided into 64 (75 - 11) spaces, admits of these minute spaces being subdivided into three of 20" each; and if the adjustment for distinct vision would allow these to be bisected by estimation, the smallest quantity to be measured would be 10" on this scale, which is indeed as small a quantity as the power of the telescope is capable of distinguishing; and therefore a longer scale would have been of no greater use. The peculiar advantage of this construction is, that, as in Hadley's sextant, a motion in the instrument does not injure the accuracy of the observation, or impede the operation of taking it, but affords the opportunity of re-examining the exactness of the apparent contact. Hence the use of this instrument affords a pleasing exercise, and the necessity of a stand is entirely obviated. We have the authority of Tully, the only maker, to say, that his grace the duke of Wellington had one of these telescopes, with silver tubes, presented to him by a friend, and there is reason to infer, that his using it as a coming-up glass gave him the advantage of ascertaining, better than any of his staff, in what direction the enemy was moving on certain critical occasions. For when it is ascertained by observation, whether the angle subtended by a man in motion is increasing or diminishing, it is easy to infer whether the man is approaching or receding, though the exact measure of the angle be disregarded. And at sea it is equally easy to ascertain whether a ship is gaining or losing ground in a chase, when two points in a mast can be distinguished. When this patent telescope has the divided object-glasses as the sliding one, the two images appear exactly similar to those in Dollond's divided object-glass micrometer, but the range of scale is much greater: if Dollond's has any advantage over this, it is, that the power of his telescope is usually greater, and that the measures taken at different stations do not depend on two adjustments of the tubes longitudinally, though it is necessary always to have distinct vision, when the edges of the images are brought into contact. We consider that neither of the constructions of the patent telescope, on its present scale, is competent to the measurement of distances from one station with sufficient accuracy; neither has it a range of scale sufficient to make it generally useful for all angles. The writer of this article has had the divided object-glasses made to have their centres adjustable to different distances from each other, so as to be capable of measuring all small angles from 1' up to 75', and to be estimated by the same scale in the different positions, the value of the first and last positions of the tubes being determined experimentally for each position of the semi-lenses, and the marks for the positions being so made, that when the scale runs out in the first position of the semi-lenses, the same value shall begin the scale at their next position; and thus a succession of minutes is continued from unity to the extreme end of the scale at the last position of the glasses; consequently one such instrument is capable of doing as much as several instruments with different pairs of semi-lenses can do, when put in a fixed position according to the patent. But after all, the initial and final values of a scale of a given length must depend on the difference of the focal lengths of the principal and sliding object-glasses; and, therefore, to observe the nice variations in the diameter of the sun or moon, it would be desirable, that the whole scale should measure only about 5', viz. from 28' to 33'; and then, if the telescope had power enough, the subdivisions of the scale might ascend by single seconds. Indeed it is yet a defi-

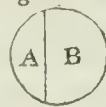

TELESCOPE.

defideratum in astronomical instruments to obtain an unobjectionable, and at the same time an easy method of measuring, by a micrometrical telescope, the distance between two very small stars, so near to each other as to be called *double stars*; for when so much extraneous light is admitted into the telescope as to shew the spider's lines, or scales of a mechanical micrometer, the minute stars vanish; and, when optical micrometers with double images are used, the light is so divided between the images, that the star also vanishes, in this case, from want of light. Dr. Maskelyne's prismatic micrometer is, perhaps, less liable to this objection than any other, but is not yet brought into common use.

Before we dismiss this part of our article, we beg leave to state, that about a hundred years ago, De la Hire contrived a method of giving different values to a pair of wires fixed in the focus of the principal object-glass of a telescope, by means of another moveable object-glass; and also that about the year 1771, Mr. James Watt, celebrated for his improvements on the steam-engine, not only contrived the same thing, but actually made the measurement by a longitudinal scale marked on his tube, nearly as done by Dr. Brewster. Mr. Watt's claim to *originality*, we believe, is undisputed, and may be proved both by his letter on the subject to Mr. Smeaton, written near that time, which letter is still in existence; and also from the circumstance of his having about the same time described his new instrument to the late Mr. Ramsden. With these prior inventions, however, we are well assured Dr. Brewster was not acquainted at the time of his taking out a patent, in conjunction with Mr. Harris, the present vender of the patent telescope; and therefore he also is entitled to the merit of *originality*; and moreover appears to have the sole right to the idea of converting it into a general micrometer, of applying it to the divided object-glass, and of converting a Gregorian or Cassegrainian telescope into a micrometer, without any additional lens or mirror. Mr. Watt never made much use of this micrometrical telescope, the impression on his mind being, that the scale ought not rigidly to be a scale of equal parts, which Dr. Brewster has since demonstrated to be the case, and his line of business not leading him to finish all the adjustments for real use.

This ingenious gentleman had previously, *viz.* in the year 1770, constructed a micrometer, with a pair of parallel horizontal wires, crossed by a single wire at right angles, in the principal focus of an ordinary telescope, which acted as a micrometer for determining distances at one station thus; a twelve-foot rod had a circular disc of wood, eight inches in diameter, painted white, that was crossed by a red horizontal line of an inch in width, which disc was made to slide along the rod, while another similar disc was fixed fast about a foot above the ground, when the rod stood in a vertical position; then, at any unknown distance, the sliding disc was lowered till one wire of the telescope covered its red line, while the other wire covered the red line of the fixed disc; and then a scale upon the rod, graduated by experimental measures, indicated the distance by inspection to within $\frac{1}{125}$ part of the whole. This instrument was used with a telescope of only twelve inches focal length, and an eye-glass of an inch and a half focus, so that the magnifying power was only eight times with this instrument. The survey of the intended canals of Crinan, Gilp, and Tarbert, was made by Mr. Watt in 1772, as well as the survey of the canal running from Inverness to Fort William, called the Caledonian canal, in 1773. This contrivance was shewn to several friends, and amongst them to Mr. Smeaton, though an account of it has never before been published. In the year 1778, a Mr. Green applied to the Society of Arts in the Adelphi for a premium for a similar

invention; on which occasion, Mr. Smeaton advised Mr. Watt to attend at the Society's rooms, to state the *priority of his claim*, which was accordingly done; but as Green's telescope had more magnifying power than Mr. Watt's, *viz.* 40, and was supposed on that account to be more accurate in determining distances, the claim of priority was ceded in Green's favour, and Mr. Watt's invention was suffered to go unnoticed by the Society.

A double-image micrometer was also invented by Mr. Watt in the year 1771, which, as it has never been described, we shall make no apology for introducing here, in company with his other ingenious inventions. This instrument consisted of a circular disc of glass, whose plane sides were not strictly parallel, but formed with each other an angle of one or two degrees, say a wedge or prism of one or two degrees. This disc or prism was cut by a diamond, at right angles to the slope of the prism, into two unequal segments thus;  The lesser piece, A, was fixed, while the larger piece, B, was moveable upon the diamond-cut line, as upon an axis or hinge, as seen in this plan, in which the dotted lines shew one of the positions into which B may be moved.  When the two segments remain in the same plane, they refract all the rays, which pass through them equally; but A remaining fixed, and B moving upon a centre, as drawn in dotted lines, the rays which pass through B, will be more refracted than those which pass through A, and this will vary with the angle which B makes with A. This divided prism being fixed in the focus of (or before) the object-glass of a telescope, two images are formed of every object by which its diameter may be measured. An index and divided sector of a circle serve to measure the comparative refractions. This instrument, however, has the fault, that the divisions are not equal parts for equal angles, and moreover the prisms would require to be achromatic, where high magnifying powers are required.

It was not till the year 1777, that the abbé Boscovich published an account of the prismatic micrometer of the abbé Rochon made of rock-crystal, with double refraction, and also of his own improvement, or substitution of glass prisms, where one of them revolved round an axis of motion like Mr. Watt's; nor was it till the same year that Dr. Maskelyne published his account of a prismatic micrometer, that measures a small angle by the refracting angle and the distance of the prisms from the focus of the object-glass conjointly; where the length of the telescope was the scale of measurement. See Phil. Transf. 1777.

Reflecting.—We proceed in the next place to describe the construction of reflecting telescopes. *Fig. 1. Plate XXX.* shews the figure of a reflecting telescope of either the Gregorian or Cassegrainian kind, for their external appearance and mode of using are the same, though we have shewn that their small specula are differently formed. After the minute description that we have given of the stands for achromatic reflecting telescopes, we may avoid prolixity, by giving a less minute account of those that have been appropriated to reflectors, where the uses of the same parts are the same: A B is the main tube of a reflecting telescope of moderate size, which may be either with or without a finder, as the power may require, mounted on the tripod G F; at A is the open aperture, and a little short of it, within, is the small speculum, drawn in or out by the screw C, which is connected with a longitudinal bar of metal, into which the heel-piece of the stem of the small speculum slides, so as to be taken away or put in at pleasure; within the interior end B of the large tube is the perforated large speculum, always concave, and of a proper figure to suit the face of the

TELESCOPE.

the small speculum. This large speculum is put in with some liberty, as is also the small one in a box containing a spiral spring acting against it to prevent tremors; B is the eye-piece of the Huygenian kind, of which there are usually two or three, according to the size of the instrument. The semi-circle D is racked, and the handle H turns the screw that gives elevation, while the handle I gives the horizontal motion, by its screw driving the racked horizontal plate E; both which are clearly seen in the figure. The vertical motion takes place at the centre of gravity of the tube at the top of the frame between E and D, and the horizontal motion is from an axis in the centre of the racked plate E, which axis has a long bearing down a tube to G, under the junction of the three legs. The three-barred bracing piece F has a joint at each leg, and also at the circular brass plate in the centre, so that a little force applied under this plate will raise it, and allow the legs to come together into contact, as well as the three arms that keep the legs open when the stand is used. This mounting is very portable and steady, particularly when the tube is short, and is every way convenient for use, except that both the vertical and horizontal motions are slow motions, the former of which is tedious when a great change of altitude is wanted in a given time, but the latter is in some measure remedied by the portability of the stand, which may be easily turned altogether, to face any particular object.

When the length of the tube is three feet and upwards, and proportionably wide, *fig. 2.* represents a stand that is greatly to be preferred to that represented by *fig. 1.* We shall put the same letters of reference to the same parts, though there is a difference in the constructions that may require explanation. This stand was contrived and first made by Tulley, who, we understand, claims also the invention of the three-armed brace F, in *fig. 1.*, above described. The contriver has evidently contemplated all the requisites for a good construction, and has succeeded in the execution of his plan: A B, as before, is the main tube, B one of the eye-pieces, C the adjusting screw for distinct vision, hid in our drawing behind the tube; but in place of it is seen the finder, attached above the eye-end of the main tube. At D is a sliding-piece of metal with a cylindrical hole, through which the round rod H D passes, and to which it may be fixed, by the pressing screw D, in any given elevation; to this sliding-piece D, two rods D K, D K, are attached by two joints, and two other joints attach them below to the frame E K, so that these rods K, K, are at liberty to rise and fall as the tube is elevated or depressed, but not until the sliding-piece at D has moved along the rod H D. When the piece D is fixed to the rod by the screw of pressure, it forms a point of bearing for the tube at a distance from the centre of motion, which is at the centre of the tube's gravity above the frame of brass work, seen in the figure; thus the telescope is kept steady by two points of bearing in every degree of elevation, though these points will recede from each other gradually as the telescope is depressed towards an horizontal position. When the screw at D is turned back, the motion is sufficiently quick; but when it is fast, the slow motion is produced by the handle at H; for while this handle turns the rod, a screw cut on its interior end works in a fixed cock, near H, that has a female screw within it, and draws the sliding-piece and rod together towards the eye, and thus elevates the tube, while the joints of the rods K, K, allow a corresponding elevation in them; so that, without undoing the screw at D, a slow motion up or down is produced by merely turning the handle H, which motion, being free from jerks, is very pleasant. Between the brass frame bearing the telescope and the large wooden frame E F,

are three circular plates, the uppermost of which is attached to the brass frame, or may be laid to form the basis of it, and has an axis of steel fast in its centre; the second circular plate is racked at the concave edge all round, and has a circular hole in the centre, just large enough to receive the steel axis we have mentioned; the third circular plate forms the top of the wooden tripod, and has also a hole in its centre, just sufficient to admit the steel axis above described; but its diameter is somewhat less than the diameter of the racked plate next above it, so that a rim, made fast to the racked plate, surrounds it, in the manner of a box-lid; but there is no other fastening of these three plates together, than the pressure occasioned by the superincumbent weight of the telescope, and of its subjacent frame E K K: the axis, or screw, of the handle I is made fast to the uppermost plate of the said frame, and takes hold of the notches in the racked plate below it, so that when the telescope is turned round in azimuth, by a quick motion, it takes the frame under it, and also the racked circle, round along with it, while the stand or wooden four-footed frame E F stands quiescent; but when the quick motion is finished, the handle I is still in its place at the eye-end of the tube, and turning it round, will give the requisite slow motion; for turning the handle, in connection with the racked plate, turns the superincumbent frame and telescope, without any motion being given to the racked plate itself, which is now kept down to its place by simple pressure of its load above. The stand, or large wooden frame, is braced in all directions, as may be seen in the drawing, and might be advantageously made of cast-iron, as it is not contrived for the convenience of portability.

The best stand for the Newtonian telescope is that which is represented by *fig. 3.*, in which A is the elevated mouth of a seven-foot tube, and B the place of the large speculum, that reflects the rays of light back to the small diagonal plane metal near C, which, by a second reflection, brings them to a focus at the eye-piece below C, as seen in the drawing. Above C is the finder, the upper end of which has a small achromatic object-glass, and the lower end the eye-glass. The upper end of the tube rests on a support D, that is capable of being raised or lowered slowly by a pinion on the axis of the handle under D, while the lower end rests on the horizontal bar of the frame E F, that is suspended by a pulley over F; the four pivots *a, b, c,* and *d,* of the said frame, sliding in the open grooves, seen near those letters, in the main frame, keep the small frame in any given situation, and allow a free motion, first down the vertical, and then down the inclined pieces, that compose the main frame, as low as to G and H; and when the lower end of the tube has been depressed into this situation, the tube may have an elevation approaching towards the zenith: for not only is the upper end elevated by the handles at J for the quick, and at D for the slow motions; but the lower one is depressed by the handle at I, round which the cord is coiled, that goes round a fixed roller at K, and two others at L and M, before it embraces the pulley N, and is hooked to a pin at O, above the frame. The rest of the main frame is so clearly exhibited in the drawing, that no farther description of it is necessary. In some of the instruments of this construction, when the handle J is omitted, and a quicker motion in altitude is required, and also a greater elevation than can be given simply by the handle at D, the second square item that carries the pinion of the handle is raised by hand, and kept to its elevation by means of a second rack, which is set at liberty by pressing a button at P, connected with the spring-catch of the rack, when this squared item is lowered again, all which motions will be readily comprehended by

any person tolerably acquainted with the mechanism of rack-work. The quick motion in azimuth is given by sliding the lower end of the tube gently along the bar on which it rests, or by moving the whole frame, which moves on castors; but the slow motion is produced by the screw at D. It is scarcely necessary to add, that the eye of the observer is applied to the *side* of the tube near its mouth, when the finder has pointed the tube properly to its object. This stand was contrived by sir William Herschel, whose experience in the use of various stands directed him to prefer one that is not liable to propagate vibratory motion to the large speculum, and that has a point of support near the upper extremity of the tube. We have, however, seen a six-feet reflector very steadily supported on a frame similar to that exhibited in *fig. 2*; and the composer of the present article has a Cassegrainian telescope, with a three-feet tube, fixed between the cheeks of one of the doors of his observatory, which turns round with the moveable dome in azimuth, and which elevates in altitude on two pivots resting in the notches of a pair of brass plates let into the said cheeks; which mode of mounting is not only convenient for celestial observations, but is remarkably free from tremors, which advantage may be owing partly to steadiness of position, and partly to the mouth of the tube being nearly two feet advanced into the open air. If the dome had not a remarkably easy motion on three loose ebony balls, placed at equal distances, this mode of mounting a large telescope would not afford a slow adjustment for motion in azimuth, which it now does with facility.

It is always interesting to a man of science to know by what progressive steps a great undertaking is accomplished, as well as to learn under what impression the original idea was entertained of forming the plan of operations. When sir William Herschel, who was brought up a musician, resided as organist at Bath, the natural bent of his mind led him to cultivate the pleasing science of optics, and to study the theory of mechanics so far as to enable him to amuse himself with attempts to construct a reflecting telescope: his success, in an undertaking of considerable difficulty, increased with his endeavours to attain some degree of excellence; and though at first he was satisfied to pick a tolerable speculum out of some dozens at which he had laboured; yet, feeling that his experience began to give him facilities both in the contrivance and execution of his manipulations, he proceeded by degrees to construct specula of seven, ten, and even twenty feet focus of the Newtonian form, to the number of more than 400, besides several of the Gregorian kind: but as yet he was unacquainted with any certain practical method of giving a parabolic curve to the face of his metal; on which account he selected, by trial, such specula for use as he found most perfect in figure, and repolished the remainder. In all these operations there was much room for experimental observation, and the time was not expended in vain. To a mind like Herschel's, even a failure roused a feeling for a new enterprise; and it was no small step towards advancement, to have perceived the cause of unsuccessful measures: the object being attainable, the means were to be found by skilful perseverance. Nor were the labours of our optician to be confined to the formation of a speculum; his mechanical skill was directed to the contrivance and execution of various stands for telescopes of an unusual length; and in the year 1778, he produced that which is now usually applied to the Newtonian telescope, and which we have just described as represented by *Plate XXX. fig. 3*. By the year 1781, Herschel (best known by this title at that period) felt such confidence in

his improved methods of proceeding, that he erected a stand for a thirty-feet reflecting metal of 36 inches aperture, and succeeded in casting it; but to his mortification the metal cracked in the cooling. The disappointment attending this accident must have been severe, but did not damp the ardour of the mechanical adventurer, in which light, no doubt, the enterprising contriver was now viewed. A second melting of the same metal was immediately determined upon, and a furnace was constructed for the purpose, which unfortunately gave way, and the liquid metal blew up the pavement. The mortification consequent on this second accident only plunged our adventurer the deeper, that he might rise the higher in his next attempt. During an interval of some respite from optical and mechanical labours, the astronomer, however, was not asleep; and while observations were making on the rotations of the planets, with telescopes of the Newtonian form, of 7, 10, and 20 feet focal length, the little planet, at first supposed to be a comet, from its having a visible magnified disc, was discovered. This lucky event rekindled the optician's ardour, and at the same time introduced him to the notice of his majesty; who, by his liberal patronage, promoted the views of this amateur instrument-maker, and afforded facility to his future operations.

In the year 1782, a good twenty-feet reflector was finished with a large aperture, and mounted on the Herschelian stand for admitting of *front observations*, for which it is found very useful. The forty-feet telescope, or master-piece of mechanism, which is more immediately the object of our examination, was begun at Clay-Hall at the latter end of the year 1785, when, through the mediation of the president of the Royal Society, the support of regal munificence had been graciously promised; and, when the various portions of the bulky structure, which employed forty workmen of different denominations, had been removed to Slough, near Windsor, the foundation was begun, which was to be the site for the largest telescope that had ever been pointed to the heavenly regions. We will not detain our reader by describing the details of masonry, carpentry, and smith's work, which have occupied eighteen large plates, in the second part of vol. lxxxv. of the Philosophical Transactions, for their explanation, but describe so much of the instrument, and of its appendages, as are useful in making actual observations.

The best view for general representation of the Herschelian telescope, is that which has been given in plate 24. of the volume just named, which therefore we have copied into our *Plate XXXI. of Astronomical Instruments*, with some slight alterations arising out of subsequent improvements or curtailments of unnecessary appendages. This view, taken from a station to the south-west of the erection, represents the telescope elevated in the meridian line, and affords the means of seeing the front parts of the instrument, and of its numerous appendages; but does not allow the mechanism that supports the inferior end of the tube, and that gives motion in some of the adjustments, to be explained by a reference to their parts, and therefore must be comprehended from a verbal description. The foundation on which the frame-work of the forty-feet telescope is erected, consists of two concentric circles of brick-work, one 42 and the other 21 feet in diameter, both sunk $2\frac{1}{2}$ feet under ground, and tapering from the breadth of 2 ft. 3 in. below, to 1 ft. 2 in. above, where they are capped with paving-stones of $12\frac{1}{2}$ inches wide, and 3 thick. In the centre of these circles, is fixed fast into the ground by brick-work, and opposite braces of wood, a vertical beam, as a centre of motion, round which the whole structure

TELESCOPE.

may have a circular motion in azimuth, the plane of the outer circle being made perfectly level. The platform that connects the different parts of the frame-work below, has three principal horizontal beams lying parallel to each other, and three others lying parallel, crossing the first at right angles, besides various bracing-beams, that tie the whole compactly together, by iron bolts passing through the places of crossing. In our drawing, the outer circle of brick-work and masonry is denoted by the letters A B, and the circumference of the platform of wood by C D: under each opposite end of the six main beams is fixed a roller, of six inches in diameter, and eight long, having each a strong iron frame bolted into the end of its respective beam; so that the outer circle has twelve rollers: but these were not sufficient to bear the whole at 21 feet from the centre of motion; therefore eight more rollers, nearly equidistant, were fixed to strong parts of the platform, so as to be borne by the inner circle of 21 feet diameter; and thus the whole platform, with its superstructure, is capable of making a revolution, when sufficient force is applied round the central vertical beam, that enters a hole at the junction of the two central main beams, and that ascends but a little way out of the ground. Six out of the twelve rollers of the outer circle are seen between A B, the brick-work, and C D, the circular edge of the platform, and the rest may be imagined, not only on the remainder of this circle, but also on the inner circle, which is concealed. In these rollers, it is of great importance that the axes of motion all point towards the central beam round which they carry the platform, and also that their diameters and frames be precisely of like dimensions, otherwise they will not bear alike on the basis of masonry. At twelve feet distance from, and all round this moveable platform, are fixed fast into the ground eight equidistant posts, to an opposite pair of which the ends of a long pliable rope are hooked, that give the motion in azimuth; which rope, being conducted over two separate pulleys, fixed upon the platform, at opposite sides of the centre, has its ends turned in the direction of tangents, that point in opposite directions to their respective posts. The middle part of the rope is made to pass round one of the spokes of a large wheel, carried by the platform, before it winds round the axle, so as to coil up both ends of the rope equally; which rope therefore pulls by both tangential ends alike, so as to apply an equal force at each opposite pulley, while the resistance of the posts produces the requisite motion, without a strain on the centre. This mechanism gives the operator a great mechanical advantage. That part of the platform C, which connects the extreme ends of the three longitudinal beams, over the rollers at A, is made strong, and is the support for a pair of double ladders, that are seen ascending to the summit of the whole frame-work, one on each side of the large tube E; and at D is another similar support for two other double ladders, which, ascending in like manner, meet the former ones, and cross into them in such a way, as to admit of being bolted together at the points of crossing. These ladders are propped by other shorter ladders, as seen in the figure, and some upright masts, of which one is seen erected over the roller at B, ascend in like manner, and afford the means of obtaining horizontal braces at different heights, all round the frame, except where the elevated end E of the telescope requires an opening to be left between the front ladders for its different degrees of elevation. The transverse beam F G, which lies horizontally over the crossings of the double ladders, and is bolted to them, receives the hooks of the different pulleys, which we shall shortly have occasion to describe, at the same time that it connects and braces together all the ladders at their upper extremities. These ladders are

each 49 feet 2 inches long, so that the height of the transverse beam F G must be $\sqrt{49 \times 49 - 20 \times 20} = 45$ nearly, and will therefore admit of the long tube, of 40 feet in length, to be raised into a vertical position under it. Below the mouth of the large tube, a gallery H I, with its attached brackets K and L, rests upon the slopes of the interior halves of the double ladders, at K and L respectively, and may be made to slide up or down, into any state of elevation, by two systems of pulleys, and ropes going round the blocks hooked at the junction of each pair of ladders, to the transverse beam F G, as may be seen in the figure; and when this gallery is lowered to the landing of the pair of steps M, a party may be admitted into it to gratify their curiosity, the floor being 13 feet 6 inches by 6 feet $1\frac{1}{2}$ inch, and palisaded on the front, as well as partly at both ends. The bases, or sliding parts of the brackets, are prevented from slipping aside by lateral rollers of brass, acting against the straight sides of the middle pole of each double ladder, while other rollers of the same metal, acting under them, diminish their friction, when drawn up or let down by the pulleys. In the framing of these brackets, it was necessary to introduce contrivances for allowing some deviation of the gallery from an exact level, in case one of the brackets was elevated by its pulley faster than the other; which contrivances are not easily described without a reference to the drawings of the separate parts in the original account, or without inspection of the parts themselves.

The tube of the telescope, which is 39 feet 4 inches in length, and 4 feet 10 inches in diameter, is made entirely of iron; it having been ascertained that a wooden tube would have exceeded an iron one in weight by at least 3000 lbs. The sheets were first put together by a kind of seaming, that requires no rivets; and when the sides of the iron platform were cut straight, it was lifted by proper tackle into a hollow gutter, and then brought gradually, by various tools, into a cylindrical form. Various hoops are fixed within the tube, and longitudinal bars of iron, connecting some of them, were attached to the two ends of the tube, by way of bracing the sheets, and keeping the shape perfect when the pulleys are applied to give the necessary elevation at the upper end, and that the speculum might be kept secure in its bed at the lower end. The hoop by which the upper end of the tube is suspended is eight inches broad, and thicker than the rest; and the system of three pulleys, seen at N, with each a double block, has a corresponding set at O, hooked to the transverse pole G F; and the bars to which the blocks are hooked are so bent, that the moving ropes will not come in contact; nor will the elevated tube have its vertical motion disturbed by the tackle, either in ascending or descending, which was an important precaution. The lower end of the tube is firmly supported on rollers, that are capable of being moved forwards or backwards by a double rack, moved by wheels and pinions at R, which we shall not attempt to describe minutely; but the use of which every mechanic will comprehend without particular explanation. Originally there were several appendages near the mouth of the tube sliding by pulleys, or fixed to the tube, for the purpose of regulating the *swings* taken by this instrument; but as the twenty-foot reflector is now used for this purpose, they are taken off, and have been omitted in our drawing. By an adjustment at the lower extremity of the tube, the speculum is turned to a small inclination, so that the line of collimation is not coincident with the longitudinal axis of the tube, but crosses the tube diagonally, and meets the eye in the air, at about two inches from the edge of the tube. Hence no part of the head intercepts the incident rays, and the observation

TELESCOPE.

tion is taken with the face looking at the speculum, or by what the author has called, by way of distinction, the *front view*, the back being always turned to the object to be viewed. Besides the pulleys of elevation, and of azimuthal motion, there are others for the purpose of communication, as well as speaking-pipes, repeating-bells, and signals by clock-work, which cannot be clearly comprehended without inspection, or numerous drawings to be referred to; but the dexterity of the observer has rendered some of these superfluous. The large speculum is enclosed in a strong iron ring, braced across with bars of iron, and an enclosure of iron and tin sheets makes a case for it; it is lifted by three handles of iron attached to the sides of the ring, and is put into and taken out of its proper place by the help of a moveable crane, running on a carriage, which operation of course requires great care. Three small vanes attached to the edge of the tube at the mouth, assist to put the line of collimation right, when they are seen reflected from the speculum to the eye-piece. We visited Slough lately, with a view of examining all the minutiae of the stupendous apparatus that is rendered necessary for the management of this huge telescope, and that can only be well described on the spot, and found the substance of a letter written by the late Mr. Smeaton on this subject, immediately after a visit for the express purpose of inspecting the apparatus then in existence, so accurate, that we avail ourselves of this source of information; and as the letter which is before us is a copy taken from the writer's own manuscript, we have no doubt of its authenticity. It relates however principally to the twenty-feet instrument.

Gray's Inn, Nov. 4th, 1785.

"My dear friend,

"Since my last, I have been to pay my visit to Mr. Herschel, and according to my promise, proceed to give you some account of what I have seen; and indeed he has so much originality about him, as well as natural ingenuity, accompanied with great readiness and dexterity, that to enter into the detail would be far to exceed the bounds of a letter; I will therefore enter into the great outlines, and fill up as I can. You must know that, till this visit, I have held the doctrine about telescopes that I believe is the common one; that, having fixed upon a proportion that you by experience find to do well in any one species of telescope, what you are to expect from any other size of the same species, is in proportion to the square root of the length; so that increasing the length four times, your telescope will allow you to take an image of double the diameter; every point of it being illuminated with the same quantity of light, and painted with an equal degree of distinctness and precision. This idea and expectation I carried with me to Thornhill, and carried the same to Clay-Hall; but I did not bring it back with me. Mr. Herschel's doctrine will illustrate his pursuits better than minute descriptions. Whatever his doctrine originally was, experience has taught him that large surfaces of speculums are not to be ground and polished so as to preserve so accurate a figure as those of a small or moderate size; he therefore divides the maximum that telescopes may be expected to bring out, into three distinct classes; first, the greatest possible degree of magnifying power, where there is a sufficiency of light; secondly, the greatest degree of distinctness, where there is also a sufficiency of light, but where the natural size of the object does not require the greatest degree of magnifying power; thirdly, the greatest degree of light, where the objects are naturally obscure, which will afford discoveries that cannot be brought out either by great degrees of magnifying power,

or a capacity of distinctness, where, on these accounts, a sufficiency of light is wanting. In conformity with this doctrine, his principal discoveries have been made upon the stars, where the greatest degree of magnifying powers have been required, and used with his original telescope of seven feet focal length, which he has pushed to between six and seven thousand times. The greatest discoveries have also been made with these, where the greatest distinctness has been required, and a moderate degree of magnifying power; the diameter of the speculum of this telescope being no more than $6\frac{1}{2}$ inches: and also, for the same purpose, he finds his ten-feet telescopes applicable, the diameter being 9 inches; but for objects naturally obscure, he can distinctly see an object with his twenty-feet telescope the diameter 19 inches, (which is seldom charged with a magnifying power of more than 200 times,) which the others will not reach. With this telescope he is now and has been for some time past at work, as he calls it, *sweeping* the heavens. The whole apparatus can upon occasion be turned to any azimuth, but is chiefly used with the telescope turning in the plane of the meridian. The inferior or speculum end of the tube is supported immediately upon the ground; the other end of the tube is raised and lowered by a tackle, supported at top upon a double equilateral triangle (or thereabouts); the observer is also hoisted up in a chair, that works on rollers, upon the inclined legs of the triangle next the eye-glass; and the eye-glass is brought to answer to this straight line by sliding the butt of the telescope near the centre of the whole machine; and by the same means it can be put into a vertical position. The raising the chair and the sliding of the butt are done by separate tackles respectively, touched only occasionally; but the main tackle that raises the telescope, when brought to its intended elevation, that is, polar distance, is worked by a distinct motion, that causes it to rise and fall alternately through a space of two degrees of the meridian, which being done with some degree of briskness, a plot in the heavens is examined at once of two degrees broad, the motion of the heavens in AR bringing on the objects in succession. By way of register, large sheets of paper are prepared, marked and numbered, being ruled into parallel long and cross lines at a quarter of an inch distance; a small square of this kind representing a quarter of a degree in AR and declination: all those that are examined being marked with a cross, and those that have been seen, but not fully examined, with a stroke one way; and when afterwards seen to satisfaction, the cross is completed. The place and species of the object are also marked upon the paper. In this operation, three persons are concerned; a labourer works continually the handle backwards and forwards for performing the destined range; and in this he is prevented from ranging too little or too much, by a small piece of machinery, that strikes a bell at each end of the range; he also stops on notice; and if any thing comes requiring this notice, and the object to be pursued, the telescope can by an apparatus, which occasionally heaves it from its meridian bearing, pursue it in right ascension for near a quarter of an hour; and that there may be no need for the observer's eye to be taken from the eye-glass, an assistant (Mr. Herschel's sister) sits in an adjacent room with the squared sheet before her, who notes down and in a book writes what is dictated. The time she has by the clock facing her, and the polar distance by a piece of machinery, which continually shews the degree and minute, and is worked by a string actuated by the telescope in rising and falling, which comes into the room, and winding round a barrel, performs the requisite motions. The telescope is set to its

altitude by a small quadrant fixed over it, and the correspondent index is regulated answerable to the stretching of the cord of communication, by observing the first known star that passes of Flamsteed's catalogue. By this means, what has been done and what is to do is distinctly seen by the sheets. In this way, many hundred nebulae have been discovered, not only unknown before, but which no ordinary telescopes will reach. The speculum of the great telescope of 40 feet is cast, but was not got home; it is four feet diameter, and about 1050 lbs. weight. Mr. Herschel tells me there is a warehouse in Thames-street, where they keep for sale metal ready made into ingots, of which they have two sorts, what they call white metal and bell-metal; I suppose such as the bells of clocks are made of, but he did not know exactly their composition: for his speculum, they put two ingots of bell-metal to one of white metal. He thinks it a lower metal than what he used for his former specula of 19 inches, viz. $7\frac{3}{4}$ ounces of tin, to 20 ounces of copper. I am not sure, however, whether I remember right, but you probably will guess. He does not propose it to magnify more than the present one of 19 inches, but to take the whole advantage in light, he makes all his specula flat upon the back side. The thickness of this last great one at the edge was to have been two inches, but by some shrinking in the mould, and particularly in the middle, I understand it is not there above $1\frac{1}{2}$ inch, and also less at the edge than it was to have been, so that it is hollow in the back as well as face; but as it came pretty well upon the face, he promises to make use of it; and when he has got thus furnished, he promises to cast another, having duplicates of all he makes, so that while one is in use, another can go to the polisher. They are made to be enclosed in brass boxes, and their weight lays simply upon several thicknesses of cloth, and are polished in these boxes, and are made to go in and take out so conveniently, that they are very frequently put into their tubes and tried with an object while under the operation of polishing; and to these frequent trials he ascribes the principal cause of his success in these operations.

* * * * *

I remain, dear sir,
ever your's,
J. Smeaton.

We have only to add farther, on this subject, what we learnt in a conversation with sir William Herschel, that he prefers single lenses, before what are called achromatic eye-pieces, from an idea that more light is thus had for both his 20 and 40 feet reflectors, and that greater power may thus be obtained for his smaller instruments. We have, however, to regret, that his mode of giving the parabolic curve to the great speculum, by mechanical means, must for the present remain a secret, for the disclosure of which we feel that we have no right to ask, while there is an existing manufactory that might be injured thereby. The peculiar advantage of the Herschelian construction is, that there is no light lost by a second reflection, and that the large quantity of polished surface reflects more rays than can be collected by any other means. The weight of the metal, which is very brittle when of the best mixture, made it necessary to have a prevailing portion of copper in the large speculum, which is, therefore, liable to be the sooner tarnished, and to require more frequent polishing than would have been requisite, if the best proportion for brightness could have been preserved in the ingredients of the compound metal: but what is defective in quality, is compensated by the quantity of polished surface. It is hardly necessary to inform the practical astronomer, that when the

greatest powers are used, both the light and the field of view, and consequent time of apparent passage through the field, are proportionably diminished. We understood the ingenious and dextrous observer to say, that instruction and practice are necessary to enable any other person to follow a star or planet with the forty-foot reflector; for that a heavenly body seen with one of the highest powers does not continue in the field more than a few seconds of time, unless the motion of the tube is regulated so as to keep pace with the apparent motion of the body; and this is probably the reason why few persons have been in a situation to form an estimate of the merits of this transcendent instrument. For the detail of all the parts, see vol. lxxxv. of the Philos. Trans. of London, part ii. 1795.

5. *On the Powers, &c.*—After having described the most convenient constructions of a telescope, of both the dioptric and cata-dioptric kinds, we proposed to shew how their powers may be practically varied and estimated. We have already seen, in our section on the theory of telescopes, how the powers may be calculated, when the focal distances of the glasses are known. In telescopes with one object-glass, or concave speculum, and one eye-glass, the solar foci of which may be called F and f respectively, the power P may be always expressed by $\frac{F}{f}$; but F varies inversely with the

distance of an object viewed, while f remains the same, therefore the power P will vary also inversely with the distance. So long ago as in the year 1740, Benjamin Martin, to whose ingenuity the practical opticians of the present day are much indebted, proposed to determine distances at one station by this variation of power in a long telescope; but as the distance increased, the proportional elongated portion of the sliding tube containing the eye-glasses became so small, that the scale was too limited to be of any real use. We mention this circumstance, merely to shew that the same telescope with the same glasses has its powers naturally varying with the distance, but in an inverse ratio, until the incident rays become parallel in consequence of the great distance of the radiant object; hence we may account for the reason why the famous Short attributed to his telescopes powers which they did not possess, when directed to very distant objects. But, generally speaking, when we say that a telescope magnifies fifty times, we are understood to mean, that it enlarges the diameter of the sun, or of some distant object, so many times; because in this case F and f remain both unaltered. (See LENS, 5.) But when the object viewed is at no great distance, calling the elongated portion of the solar focus e , and the distance d , Martin has shewn that

$e : F :: F + e : d$, or that $\frac{F + e \times F}{e} = d$; and he proposed to determine the quantity of e in all situations by mechanical measurement.

Now supposing the power to be considered as always determined from the solar focus of an object-glass or speculum, in telescopes of the simplest construction, this power, where the object-glass or speculum remains the same, can be increased only by shortening the focus of the eye-glass or eye-piece, when it is composed of two glasses; but there is a limit in the power of dioptric telescopes constructed with single object-glasses, which depends on the prismatic and spherical aberrations, beyond which limit *indistinctness* takes place; and even in good achromatic and reflecting telescopes, the eye-piece may be shortened until a deficiency of light renders the increased power of little use, and thus fixes a limit to useful power.

After a power is fixed on, in the use of a simple telescope,

TELESCOPE.

scope, such as admits of sufficient light, and allows a field of view large enough to contain the images of the object to be examined, the magnitude of this power may be ascertained by different means, besides $\frac{F}{f}$, which expression is better cal-

culated to explain the theory than to define the practical result; for it is not an easy matter to measure precisely the *exact* compound solar focus of an eye-piece composed of two glasses, nor yet that of a single lens, when its focus is short, and consequently its substance considerable in thickness. Neither is it easy to obtain the *exact power* of a terrestrial eye-tube constructed on the principles of a compound microscope. The first practical method of measuring the total power of a telescope, that we shall describe, is extremely simple, and is applicable to telescopes of all constructions, however complex the calculation by theory may be, and gives the result with very little trouble. Whatever be the diameter of the object-glass or speculum of a telescope, in inches and parts, the diameter of its image, or luminous disc, formed in the anterior focus of the eye-piece, by the condensed rays, will bear the same proportion to that diameter, as the focal length of the eye-glass or glasses jointly, bears to the focal length of the object-glass or speculum; these diameters, therefore, may be substituted for the two foci of the respective glasses, or speculum and its eye-glass, in determining the power. Different methods of measuring the luminous disc have been proposed; a nicely divided slip of mother-of-pearl, fixed in a small piece of tube bearing a magnifier at the opposite end, forms a simple instrument, which has been called the pearl dynameter, (from *δύναμις*, of power, and *μετρον*, a measure,) and which answers the purpose very conveniently, when sliding within another short tube for the sake of adjustment, as is seen in fig. 9. Plate XXIX.

Suppose that the disc of a telescope, with an object-glass of 3.25 inches diameter, measures $\frac{1}{200} = \frac{1}{1000}$ of an inch by

the pearl dynameter, then $\frac{3.25}{.06} = 54\frac{1}{2}$ is the power required

to be measured: and if the same disc had been measured with a reflecting telescope of 7.5 inches diameter of the large speculum, whatever its construction in other respects,

the power would have been $\frac{7.5}{.06} = 125$. The correctness of

this simple method will depend on the accuracy with which the respective diameters of the disc and object-glass, or speculum, are taken, and the distance to which the telescope is adjusted for distinct vision. The powers of the four achromatic telescopes, for which we have adapted our Tables I. and II. in the next section, were taken in this way, when Troughton's micrometer was applied as a celestial eye-piece, and were determined to be as follow: *viz.*

In.		
30.15	focus	$\left\{ \frac{2.05}{.0663} = 30.5 = \text{power.} \right.$
45.75	ditto	$\left\{ \frac{3.3}{.077} = 45.3 = \text{ditto.} \right.$
63.5	ditto	$\left\{ \frac{3.5}{.0512} = 63.5 = \text{ditto.} \right.$
118.8	ditto	$\left\{ \frac{3.000}{.052} = 120.0 = \text{ditto.} \right.$

These powers, if the data had been taken with perfect accuracy, would have been respectively to each other as the focal lengths of the object-glasses directly, which they are nearly, or inversely as the values of the micrometrical screw, which values have been tabulated, as will be seen in our

subsequent section; therefore, when the power of one of the telescopes is obtained accurately by the pearl dynameter, the powers of all the others may be had from the micrometrical values, by reciprocal proportion. Before, however, the dynameter is used, it will be necessary to adjust the eye-piece to distinct vision when viewing a remote object, otherwise the disc will be too small, and the power larger than when celestial observations are taken. Also, to avoid mistaking the anterior glass of the eye-piece for the disc or diminished image of the object-glass, a slip of paper may be stuck on the centre of the exterior face of the object-glass, the image of which will appear on the centre of the disc, and assist the adjustment of the dynameter to its true place of distinct vision, which is essential at the moment of taking the exact measure of the disc. If one of the celestial eye-pieces has got a divided slip of pearl, as recommended by Cavallo, to be used as a micrometer, the interior lens may be taken out, and then the eye-piece will become a dynameter for measuring the powers of all the other eye-pieces, whether celestial or terrestrial, in the way we have here described; but it will be more convenient to use one with a sliding tube of adjustment for distance, as made by T. Jones, of Charing-Cross.

As this dynameter has lately been constructed in an improved manner, by the maker we have just named, and as it has never been described, we will here give our readers a short account of its improved construction. Fig. 9. of Plate XXIX. represents this neat little instrument of nearly its full size, where *a*, *b*, and *c*, are so many small tubes within one another: the shortest tube, *a*, contains the two plano-convex lenses *f* and *g*, which constitute what we have called the positive, or Ramsden's eye-piece, with the two curved faces opposed to each other; and as this eye-piece screws into the tube *b*, near the end *g*, it may be considered as a part of this tube, when screwed into its place: the tube *b* has a slip of the mother-of-pearl, *d d*, very delicately made, and screwed fast across a diaphragm near its remote end, at such a distance from the lens *g*, that the screw of the eye-piece *a* will adjust the pearl for distinct vision, as an object in the compound focus of the eye-piece, for any eye that may have occasion to use it. The slip of pearl is divided into such minute parts, that 500 of them are equal to an inch, and yet the eye-piece has power enough to give a clear view of them, and to enable the eye to count the dividing strokes, of which every fifth is of double, and every tenth of four times the length of the subdividing strokes. When the scale is rendered clearly visible and legible, by the screw of adjustment, the tube *b* is inserted into the outermost tube *c*, which has a diaphragm and covered hole at *e*, and when this hole is uncovered, tube *c* is brought into contact with the eye-piece of the telescope, centre to centre, so as to receive the pencil of condensed rays, that usually enters the eye of a spectator; then, if the image of the object-glass of the telescope formed at the place of the eye, is not well defined on the slip of pearl, tube *b* must be pushed into tube *c*, till this will be the case, and then the number of divisions and sub-divisions of the pearl scale, that the little luminous circle exactly covers, will give the measure required; and if the number read be *doubled*, because they are 500th parts of an inch, they will then be so many parts out of 1000, and will therefore be decimal parts of an inch; the denominator being considered = 1000.

Another method of ascertaining the powers of a telescope, when a dynameter is not at hand, is by what is called *false vision*, which requires a little practice before it can be applied with success. By this method, one eye views the magnified image of a distant object in the telescope; and the

TELESCOPE.

the other eye, being also used, but *out of* the telescope, projects that image upon a horizontal line, bounded by some observable distinct marks, that can be known again: then as often as the angle subtended at the place of observation by the object, of which the image was observed, is contained in the angle subtended by the horizontal line into which it was projected, so much does the image apparently exceed the object; *i. e.* so much does the telescope magnify. For instance, suppose that forty bricks in the wall of a distant building appeared just to occupy the whole field of view of any telescope, and that the angle subtended by those bricks measured 50', by any other instrument, which would be the case at the eighth of a mile very nearly; then suppose that the horizontal line covered by the forty magnified bricks, or by the luminous circle of the field of view, was bounded by two trees, and subtended an angle of 41° 40'; on these

suppositions, the power would be $\frac{41^\circ 40'}{50'} = 50$: and in

this way, but not so well as by the pearl dynameter, a telescope composed of any number of glasses, or specula and glasses, may have its power determined, without any regard to the radii of the glasses or specula, or to their respective positions. Should the results of the two methods accord, it may be taken for granted, that the determination arising from the average is sufficiently accurate. The powers of the four telescopes with the same eye-piece, which we have before mentioned, were taken again by this second method, and found to be as in the subjoined statement; *viz.*

In.	30.15 focus	-	{	681'	=	30.9
				22'		
	45.75 ditto	-	{	681'	=	47.0
				14'.5		
	63.5 ditto	-	{	681'	=	64.8
				10'.5		
	118.8 ditto	-	{	681'	=	121.6
				5'.6		

In taking these measures, it was found convenient to make use of the space included between the two spider's lines of Troughton's micrometer, instead of the whole field of view; which substitution not only prevented distortion, by confining the objects to the middle of the field of view, but diminished the angle to be projected within the dimensions of the pupil of the eye, so that the head did not require to be turned from its first position in making the projection. Two painted staves were stuck into the ground at about 700 feet from the eye, at such a distance from each other, that they could both be seen within about one-half of the field of view; the spider's lines were then opened till they coincided with the two staves, when projected upon them by false vision, and the value of the revolutions was then found to be as above stated. This was done with the telescope of 30.15 inches focus; but the same projection would have taken place at the same opening of the lines, with any of the other three telescopes at the same distance from the staves; therefore it was not necessary to repeat this operation with the other telescopes, because the respective values of the same opening, or number of revolutions, are given in our Tables I. and II., as will be seen presently, for all the telescopes, as so many divisors for the common dividend. Thus Troughton's micrometer may be used with great advantage in determining the power of any telescope to which it is adapted; and even Cavallo's may be substituted for the same purpose, when that eye-piece is used to which it is appropriated. But the most convenient, as well as most ac-

curate dynameter that we have seen, is that which has an eye-glass divided, so as to form two images of the luminous disc, when the centres of the semi-lenses are separated by a screw with a divided head. This double-image dynameter was invented by Ramsden, probably soon after Dollond's object-glass micrometer was invented, and is now made by G. Dollond, and also, with some variation, by Thomas Jones, of Charing-Cross, who was a pupil of Ramsden's school. As this elegant and useful little instrument has not been described, we shall introduce a short account of it in this place. *Fig. 12. Plate XXIX. of Astronomical Instruments,* represents the exterior appearance of Mr. Dollond's construction, and *fig. 14.* its plan, when the covering plate is taken off; in both which figures the same letters refer to the same parts. The frame that contains the screw is denoted by *a*, and *b* is the interior or sliding-tube of brass, made fast to the said frame, having the divided lens at the eye-end, near the letter of reference *a* in *fig. 12*; and *c* is the outer tube, which is placed in contact with the outermost eye-glass of the telescope, when the luminous disc is to be measured, and admits of adjustment of the tube *b* to distinct vision of the disc: *d* is a milled head of a concealed screw, which separates the two semi-lenses until the luminous disc is seen double, with the opposite edge of each disc nearly in contact, as in *fig. 13*: *e* is the divided head of the screw, or micrometrical head, with 100 divisions properly numbered; and *f* is the scale for indicating the number of revolutions of the screw, as the divided head *e* does the parts of a revolution. The axis of this screw is made fast to the frame, so as not to move from its situation while it revolves, and is of bell-metal; it is made hollow within, and is tapped to a thread of the same fineness as that of the exterior screw; then a smaller screw of steel enters the tapped tube, as seen in *fig. 14*, and has its other end pinned fast to the piece of brass *g b*, at the point *g*, which piece carries one half of the divided lens, while the other half is carried by a similar piece, *b h*, to which the scale *f* is also screwed fast. The foot-piece of *b h* is tapped, so as to receive the thick screw of the axis; and a bent spring of metal, *i h*, bears against both pieces, *g b* and *b h*, so as to keep the screws connected with them free from shake. During this description of the concealed parts of the frame, the mechanical reader will have anticipated, that when the micrometer head, and nut *d*, made fast to the axis of the thick screw, turn together in the direction that makes the figures increase, the thick screw will draw the piece *b h*, and with it the scale *f*, and one semi-lens, towards the nut: but as the small screw of steel is a left-handed screw, *i. e.* has its thread winding in a contrary direction, and is fast to the piece *g b*, it will recede from the nut, and take the other semi-lens in a contrary direction, so that the centres of the semi-lens will separate with a velocity equal to the sum of the contrary motions of the two semi-lenses; and as these centres recede, the original disc will become a double disc, as in *fig. 13*, and may by separation be made two discs, when the semi-lenses are removed to their greatest distance. Hence, when the value of one revolution is known, the amount of any given number of revolutions and parts is had, as being multiples of that revolution. In the dynameter before us, there is a disc of thin horn or ivory, just $\frac{1}{16}$ th of an inch in diameter, in the sliding-piece that closes the aperture of the exterior end of tube *c*; and five revolutions of the screw just divides this disc into two contiguous ones, so that each subdivision of the micrometer *e* is just $\frac{1}{320}$ th of an inch, and when doubled, may be put down in decimal numbers. But there is another use of the horn disc, besides that of giving a value to the micrometer; it

TELESCOPE.

so much resembles the luminous disc formed by the image of the object-glass which is to be measured, that the mode of dividing this disc by the screw may be illustrative of the mode of application to the measurement of the actual disc formed with distinct vision, by the refracted rays that have passed through the eye-tube of a telescope.

This instrument forms, besides, a pleasing microscope not only for viewing, but for measuring too, the real dimensions of any microscopic object; and when applied to a nicely divided scale, it may be ascertained whether or not the horn disc is exactly $\frac{1}{10}$ th of an inch in diameter; *viz.* whether or not five revolutions of the screw will bring the strokes that include $\frac{1}{10}$ th of an inch into exact apparent coincidence; for if not, a correction depending on the excess or deficiency must be applied to all measures of a luminous disc, that are to determine the total power of any telescope; or otherwise the two lenses of the eye-piece must have their *distance* between them so adjusted, that five revolutions will exactly measure $\frac{1}{10}$ th of an inch; for as the two semi-lenses, when brought to have their centres coincident, constitute one of the two lenses of a positive eye-piece, as in the pearl dynameter, and as in Troughton's micrometer, we have shewn that altering the distance between these lenses, will alter their compound focus, and consequently their magnifying power, on which the apparent magnitude of the luminous disc depends. In using this instrument, the eye is applied above the centre of the tube *b*, over *a* in *fig. 12*, and the tube *c* is used, as in the pearl dynameter, for adjustment for distinct vision of the discs.

When Ramsden first made the double-image dynameter, as now constructed by Mr. Dollond, and as we have here described it, he found that there was some play in the screws after they had been in use for some time, so that they would not immediately obey the direct and retrograde motions of the nut *d*; and that the loss thus arising affected the measure by the semi-lenses, which did not move contemporaneously; but in the instrument under our examination there is no fault of this kind.

The dynameter which Ramsden considered as an improved construction, as it regards the imperfection just noticed, is now made by his pupil Thomas Jones, who, we have said, has also improved the pearl dynameter already described. *Figs. 10.* and *11.* represent the interior parts of Thomas Jones's dynameter, which we have also before us; there is no frame *a* here, but the tube *b* contains the lenses of the eye-piece, of which that next the eye is divided, as in Dollond's instrument; and the tube *c* is the same, except that it carries a lens *k*, with which the divisions on the scale *f* are read, when the dynameter has its position reversed, after the measurement is finished. The nut *d*, and divided head *e*, are also the same as we have described; but the semi-lenses are not fixed in sliding-pieces of metal, such as we have described; neither is the screw similar to what we have above noticed. Within the tube *b* is an interior tube of much smaller diameter, and nearly of equal length, which is divided longitudinally into two similar halves, which turn on separate pivots in a gimbal, or moveable ring, within the remote end of the tube *b*, and each semi-lens is fixed in the nearer end of its own semi-tube. These semi-tubes are marked *m* and *n* respectively in *fig. 10*, and one of the pivots in the ring is at *o*; the other being at the opposite end of the diameter of the ring: the extreme ends of the pivots turn in the tube *b*. The section of the semi-tubes, holding the semi-lenses, is seen in *fig. 11*, together with the micrometer head and nut. The axis of the screw is of bell-metal, and solid: the end nearest to the micrometer head has threads of double fineness to the end within the tube, and

the action is so ingeniously contrived, that the semi-lenses are moved in contrary directions by the same screw, notwithstanding the threads all incline one way. The cylindrical nut *g* is tapped for the finer thread; and as this nut is screwed fast to the tube *b*, as seen in *fig. 11*. more plainly, the forward motion of this axis has its velocity guided by this fine part of the screw; and the end that enters the tube, presses against a stud *h*, made fast to the semi-tube of the semi-lens *1*; and a longitudinal counteracting spring concealed in tube *b*, and made fast to it at the lower end, allows the semi-tube to recede, but presses it close to the end of the screw; then another stud *l*, made fast to the semi-tube of the semi-lens *2*, is tapped for receiving the coarser thread on the axis of the same screw, which thus gives a double retrograde velocity to this semi-tube, compared with what it receives from the push of the finer screw; and as there are two threads in the fine screw for one in the coarse one, and as both are cut on the same axis, the apparent motion of the semi-lens *2*, is actually the difference of two contrary, but contemporaneous motions; and these motions are so slow, that five revolutions are equal to $\frac{1}{10}$ th of an inch, and consequently the reading is in decimal numbers already. Otherwise, this dynameter is applied exactly as we have above explained.

Besides these dynameters, we have examined a double-image one by Dollond, in which the micrometer head was divided into forty parts, and in which the ivory disc was only $\frac{1}{10}$ th of an inch, so that 2.50 revolutions measured the disc, and a double measure might be obtained by making the contact of the two discs first to the left and then to the right, in order to make the error of zero vanish, in which case half the sum of the two measures was the true measure corrected for the opposite errors of zero, and the graduated circle or head of the micrometer turned stiff on the axis of the screw for adjustment to zero. This instrument professed to have $5 \times 40 = 200$ divisions in $\frac{1}{10}$ th of an inch, and consequently only 2000 in an inch; but on examining the value of a revolution with a fine scale, we found that 198 divisions measured $\frac{1}{10}$ th of an inch: we will therefore exemplify the use of this instrument, by shewing how the correction for the imperfection of the scale may be applied in actual practice. In the first place, the screw is turned in a retrograde direction until contact of the two discs takes place to the left of the original single disc; in this situation the 40 on the divided head must be put to zero, or the lozenge marked as a pointer to the micrometer head, and the stroke indicated on the small scale *f*, by another lozenge or index, must be noted; then turn the screw, first till the two discs unite in one, where a single measure might be taken, and then till they are again in contact to the right; in which situation, the whole diameter of one disc will have crossed the whole diameter of the other, and therefore the screw and its parts will give a double measure of the real diameter. In an actual trial of a telescope, this double measure was found to be two revolutions of the screw, and 37 parts of the head, or $\frac{37}{40}$ of another revolution; and on an average of several trials, $\frac{1}{10}$ th of an inch was found not exactly equal to 200, but to 198 of the divisions of the head, as we have stated above; then $\frac{198}{200}$ of $\frac{1}{10}$ th of an inch was the double measure of the disc; or $\frac{198}{200} \times \frac{1}{10} = .0295$ of an inch was the single measure; and the diameter of the object-

glasses being 3.24 inches, we have the power = $\frac{3.24}{.0295} =$

110.1 with great correctness, the telescope having been previously adjusted for viewing the solar spots. This was the determination of the power of our telescope of 63.5 inches focal distance, when No. 4. of the celestial eye-pieces was on; and in the same way all the other powers, celestial or terrestrial,

trial, may as readily be obtained. T. Jones's construction is however more convenient for use, and is more accurate, though it measures only one disc, unless the power be great, and consequently the disc small. The divided head is fixed fast to the axis of the screw, and is divided into 100 parts, 500 of which measure exactly $\frac{1}{100}$ th of an inch, so that the inch is sub-divided into 10,000 of these parts, and the decimal numbers are read off at once without calculation: thus, when the disc is adjusted to appear single and well defined, the index, which is the edge of the scale *f*, stands at 100, or zero of the micrometer head, and the edge of the circular rim of the head is coincident with the first stroke of the scale; but when one revolution of the screw has taken place, the said edge is found coincident with the second stroke of the scale, and so on, as the divided head revolves; when the two discs were brought into contact, the quantity indicated, as seen through a lens *h*, was 2.95, viz. two revolutions, and $\frac{95}{100}$ on the head of the screw; but in this instrument, five revolutions, we have said, are equal to $\frac{1}{20}$ th of an inch, and therefore one revolution = $\frac{1}{400}$, consequently $\frac{2.95}{400}$, or .007375 of an inch, is the measure, as before; so that all that is requisite to do, in registering the measures taken with this instrument, is to prefix a cipher to the figures read off by inspection, and then the decimal quantity; or divisor, is had, without further calculation, for a telescope of any aperture, either dioptric or cata-dioptric, and of any construction.

In both Dollond's and T. Jones's dynameters the disc is seen without distortion and without prismatic colours, and the instrument forms a single microscope of the most useful kind; for, by the latter in particular, small objects may have their dimensions taken to the accuracy of $\frac{1}{100000}$ th part of an inch, and at the same time the figures may be had by inspection, from the scale and its parts, to form places in decimals when a cipher is prefixed, as we have above explained. The powers of our four telescopes, with the eye-piece of Troughton's micrometer, were found by T. Jones's double-image dynameter agreeably to the subjoined statement; viz.

In.			
30.15 focus	-	$\left\{ \begin{array}{l} 1.50 \\ .049 \end{array} \right.$	= 30.6 = power.
45.75 ditto	-	$\left\{ \begin{array}{l} 3.50 \\ .076 \end{array} \right.$	= 46.0 = ditto.
63.5 ditto	-	$\left\{ \begin{array}{l} 3.25 \\ .0504 \end{array} \right.$	= 64.5 = ditto.
118.8 ditto	-	$\left\{ \begin{array}{l} 3.000 \\ .0252 \end{array} \right.$	= 119.0 = ditto.

In all the three determinations of powers, the adjustment for vision was to a distant terrestrial object, and consequently these are somewhat too great. From the experience we have had of these different modes of ascertaining the powers of a telescope, we have no hesitation in giving the preference to the double-image dynameter, in which the two images may be brought into very nice contact: whereas in the pearl dynameter, which is also very good, something is always left to estimation in taking the fractional part of a division; and when *false vision* is used, the adjustment of the eyes to different distances, one within the telescope and the other without, at the same time, leaves considerable uncertainty in the size of the projected field of view, which will vary according to the state and position of the eye in every trial. We mention this last circumstance as worthy of consideration, because several micrometrical determinations of the distance between double stars have been made, particularly by sir W.

Herschel, where the power of the telescope determined by *false vision* is made in effect the scale of the measure; consequently if the power is not accurately assigned, the measure of the angular distance depending on it will be proportionably erroneous. Astronomers, we repeat, are yet in want of an unobjectionable mode of measuring the angular distances of very small double stars, which cannot be seen when extraneous light is admitted into the telescope, and which therefore have hitherto been projected on two luminous points, placed at measured distances from each other, for the purpose of ascertaining the apparent celestial interval in its magnified state, from a comparison with a known terrestrial interval in its unmagnified state, which method is liable to considerable uncertainty, and can only be admissible upon the principle of its admitting of an average taken from a succession of measures under different circumstances.

We have already explained, in our preceding section, how the powers of any telescope that has a terrestrial eye-tube, may be varied by the application of the celestial eye-pieces to the eye-end of this, by the help of adapters, and therefore we shall only say further on this part of our subject, that however the power is varied by changes of position of the eye-pieces, or by additional field-glasses, any of the dynameters will give the total power, under any of the dispositions, by the simple measurement of the disc, which we have explained; but should there be any doubt about the exclusion of the rays incident on the extreme circular edge of the object-glass by the diaphragm, or by Troughton's new illuminator, a measured circle, or long slip of paper, stuck to the face of the object-glass, must necessarily be substituted for the glass itself, which we were obliged to do with three out of the four of our telescopes, and then its image at the eye must be substituted for the disc, that we have hitherto described as the true image of the glass itself, which it will be only when all the rays are transmitted and refracted to a focus at the place of the said disc or image.

In all refracting telescopes, that are not achromatic, of which indeed very few are now made, the indistinctness of an object is directly as the area of the aperture, and inversely as the square of the focal distance of the eye-glass, when this is single, because the aberrations are proportional to these data; but in a reflecting telescope, the indistinctness will be, with spherical curves, as the sixth power of the diameter of the large speculum directly, and as the fourth power of its focal distance inversely, and also as the square of the focal distance of the eye-glass inversely.

The light in any telescope, refracting or reflecting, if we disregard what is lost by reflection, is directly as the squares of the linear apertures, and inversely as the square of their linear amplifications.

In refracting telescopes of various lengths, not achromatic, a given object will appear equally bright and distinct, when their linear apertures, and the focal distances of their single eye-glasses, are severally in a subduplicate ratio of their lengths, or focal distances of their object-glasses: and then also their linear amplifications will be in a subduplicate ratio of their focal lengths. But in reflecting telescopes; and in the best achromatic refractors, of various lengths, a given object will appear equally bright and equally distinct, when their linear apertures, and also their linear amplifications, are as the square-square roots of the cubes of their lengths; and consequently when the focal distances of their eye-glasses are also as the square-square roots of their lengths. See Smith's Optics, p. 140, et seq.

6. Measures taken by Micrometrical Telescopes.—Though the primary use of a telescope is to render a distant object visible,

TELESCOPE.

visible, by amplifying the visual angle, yet its application to the measurement of small angles was an object that engaged the astronomer's attention at no great distance of time from its invention. When the apparent diameters of the planetary bodies had once been increased, so as to subtend an appreciable angle at the eye of the observer, it soon became a matter of interest to measure those angles in their enlarged state. We have already given the description of the different MICROMETERS that have been successfully applied to a telescope for the purpose of measuring minute angles, and terrestrial distances corresponding thereto; but we have reserved our account of the means proper to be used in these operations, as constituting a portion of our present article. We propose to illustrate the use of a few of the most accurate and useful micrometers by such examples, as will suffice to render the application of any other micrometer intelligible.

When an object to be viewed is remote, the rays of light which proceed from it may be considered as coming from it in parallel lines, and in this case the focus of the object-glass, or speculum, is the shortest possible; consequently, the power of the instrument depending on this focal distance, is the smallest possible with the same eye-piece; but the rays which proceed from a near object, come to the object-glass or speculum *diverging*, and consequently do not come to a focus so soon as in the former case; so that the *power* is greater than when a distant object is viewed. This variation of power depending on the distance of the object viewed, is accompanied by a new adjustment of the eye-piece for distinct vision in every telescope of considerable magnitude; and the longer the focus of the object-glass is, the greater is the variation of power with the same variation of distance. Hence the angle that is measured by any of the micrometers attached to a telescope, is the true angle only when the object subtending that angle is remote; and a correction, depending both on the distance and focal length of the telescope, becomes necessary for converting the *apparent* measured angle into the *true* one. To a want of attention to this circumstance in the practical application of micrometrical telescopes to the measurement of terrestrial distances, is principally to be attributed the failure of their success; and celestial objects have consequently engrossed their utility almost exclusively. We conceive, therefore, that we shall render our readers an acceptable service by shewing, not only how small celestial angles may be measured by a telescope fitted up with an accurate micrometer, but also how terrestrial angles, subtended by objects at various distances, may be ascertained, and their corresponding distances be obtained with great accuracy; and that by simple vision at one station, when the distance is not very considerable. The composer of the present article has made experiments with different micrometers adapted to telescopes of various lengths, and can therefore illustrate the theory by actual examples in sufficient variety.

Celestial Measures.—When a micrometer of any description, mechanical or optical, is proposed to be used with a telescope, it is necessary that the value of one of its divisions be ascertained with that identical telescope when viewing a remote object, such as a heavenly body; or otherwise, that a correction for distance be applied previously to the determination of such value. We will first suppose the object at a sufficient distance to require no correction for want of parallelism of the rays of light, and will shew how to appreciate the micrometrical scale for such remote distance without correction. The diameter of the sun has been so well ascertained by actual measurement of the best instruments, from month to month, and from year to year, that it

may be taken from the Nautical Almanac, or *Connoissance des Temps*, on any given day, as a standard, from which the value of a corresponding number of divisions on the scale of the micrometer may be assigned with great accuracy, after allowance is made for apparent variation in the sun's diameter by altitude; and when the number of minutes and seconds corresponding to a certain number of divisions on the scale is ascertained, the value of one division is readily obtained by dividing the whole number of minutes and seconds by the whole number of divisions that measure the said quantity: and then whatever may have been the error of the observation, as affecting the whole scale, the quantity of it belonging to one division will be only $\frac{1}{30}$, $\frac{1}{40}$, or $\frac{1}{50}$ of the whole, accordingly as there were 30, 40, or 50 divisions in the scale that corresponded to the correct diameter of the sun. For instance, on the 7th of August 1815, the sun's diameter was measured at noon by a Troughton's micrometer, attached to a five-foot refracting achromatic telescope made by Tulley, and was found to be equal to 60.65 turns of the screw, when taken in a vertical direction, while the sun passed horizontally between the two parallel spider's lines in the focus of the eye-piece. In this situation the altitude of the sun was so great, that the difference between the refractions of the upper and lower limbs was insensible, and therefore may be neglected in the calculation of the value of the scale of notches that indicate the revolutions of the screw. On this day, the semi-diameter of the sun, as given in the Nautical Almanac, was $15' 48''.3$, and the notches corresponding to the sun's diameter were 60.65,

or 60 entire notches, and $\frac{65}{100}$ taken from the divided head

of the screw; then $\frac{15' 48''.3 \times 2}{60.65} = 31''.27$ is the value of

one notch, or revolution of the screw, according to this observation. Again, on the 15th of October, of the same year, the sun's diameter, at nine o'clock A. M., was found equal to 61.50 revolutions of the same screw, used with the same telescope, when the sun's semi-diameter is given $16' 4''.8$, or the diameter $32' 9''.6$; but at the low altitude at which this measure was taken, the difference of the two refractions of the upper and lower limbs amounted, by the table of refractions, to $2''.6$, to be subtracted from the real to produce the apparent diameter, because the vertical diameter was contracted by this quantity, the lower limb being more elevated by refraction than the upper one; therefore, according to

this observation, the value comes out $\frac{32' 7''}{61.5} = 31''.33$ for

each revolution; hence the average of the two measures, taken at different times, and at different altitudes, is

$\frac{31''.27 + 31''.33}{2} = 31''.3$, which determination accords with

measures taken at other periods, and also with terrestrial measures subsequently taken, as will appear hereafter.

When this value of the micrometer's revolutions was ascertained, the solar focus of the object-glass was exactly measured, and found to be 63.5 inches. Three other achromatic telescopes were then procured, and had the same micrometer adapted to them respectively, by as many rings of brass, which had each a male and a female screw: the former to screw into the tube of its telescope, and the latter to receive the coarse thread of the micrometer; which rings we have called *adapters*. The focal lengths of the respective object-glasses were found by accurate measurement to be 30.15, 45.75, and 118.3 inches; and the corresponding

TELESCOPE.

values of the micrometer's revolution, found as above described, were 66".0, 43".5, and 16".8; viz. exactly in the inverse proportion of their focal lengths, as the theory requires. Hence, when the value of the micrometer is known with a telescope of a known focal length, its value may be had, when applied to any other telescope of a determined focal length, by reciprocal proportion; for as 30.15 in. : 63.5 in. :: 31".3 : 66".0; and conversely, when the values are known, and the focal length of one of the telescopes, the focal lengths of all the others may be determined; which is

equally the case with the powers, depending solely on the focal lengths when the same eye-piece is used with each. When the values of the micrometer screw had been determined, both by measurement of the sun, and by mutual comparison of the focal lengths of the four achromatic telescopes, the two following tables were constructed to facilitate the use of the micrometer with any or all of the said telescopes, which we subjoin as a specimen by which other tables may be constructed by the simple arrangement of the multiples of the value of unity.

TABLE I.—Values of entire Revolutions of the Micrometer's Screw, with four different Telescopes.

The use of these tables will be best understood from a few real examples.

1. The sun's diameter was taken by Troughton's micrometer, applied to the telescope of 45.75 inches focal length, on the 27th of May 1815, when his altitude was so high as to require no correction for the difference of the two refractions of the lower and upper limbs, and was found equal to 43.62 turns of the screw: then by Table I. $43 = 31' 10''.5$, and by Table II. $.62 = 26''.9$, the sum of which is $31' 37''.4$, the diameter given in the Nautical Almanac being $31' 37''$. In this observation the thickness of the spider's line was allowed for.

2. On the 7th of August 1815, the sun's diameter at noon measured 60.60 turns, when the micrometer was used with the telescope of 63.5 inches focal length; whence we have 60 in Table I. = $31' 18''$, and .60 in Table II. = $18''.8$, making together $31' 36''.8$, the diameter in the Nautical Almanac for that day being $15' 48''.3 \times 2 = 31' 36''.6$. When these measures were taken, the telescope was on an equatorial stand, and the parallel lines were so placed, that the sun's body passed along the space contained between them, without any apparent variation of

altitude, which position is necessary in every observation taken with Troughton's micrometer, when the object has an apparent motion.

3. On the 14th of August 1815, the moon's diameter was measured about 9 P.M. not far from the meridian, when her altitude was about 18° , with Troughton's micrometer, attached to the telescope of 45.75 inches focus, and was found equal to 41.52 turns of the screw; the horizontal semi-diameter, according to the Nautical Almanac, being at noon $15' 4''$, and at midnight $15' 0''$, consequently at the time $15' 1''$. To the horizontal diameter $30' 2''$, add the augmentation at 18° altitude, (from Table IV. of the requisite tables,) viz. $5''$, and the diameter in altitude will be $30' 7''$. Now from Table I. take the value of 41 turns = $29' 43''.5$, and from Table II. take the value of $.52 = 22''.6$; the sum of which two values will be $30' 6''.1$, which must be increased by $5''$, the difference of refraction at 18° , and $18^\circ 30'$ of altitude; so that the diameter, when the reductions are all made; is too great by $4''$ nearly, which error may be in the lunar tables, or in the observation, which was made when the moon's age was only eleven days, and therefore under an unfavourable circumstance; for

TELESCOPE.

for in this situation the illuminated portion of the moon is always apparently larger than the dark portion.

4. The sun's diameter was again taken at nine o'clock A.M. on the 15th of October, with the telescope of 63.5 inches, and was found equal to 61.56 turns; when the altitude was such as to require an addition of 2".6 for the variation of the refraction in half a degree of altitude; and here we have from Table I. $60 + 1 = 31' 18'' + 31''.3 = 31' 49''.3$, and from Table II. $.56 = 17''.5$, making, together with + 2".6 the correction, the sum $32' 9''.4$, the diameter given in the Nautical Almanac being $16' 4''.8 \times 2 = 32' 9''.6$.
